Research Associate (normally with some post-doctoral experience) in the Physics Department, to assist in a programme of work on optical masers—The Principal, Royal Holloway College (University of London), Englefield Green, Surrey (August 15).

Research Engineer or Physicist (with a good honours degree in physics or engineering and a Ph.D. or equivalent experience) in the Building Science Laboratories, to work under the direction of Dr. G. H. Tattersall, on the compaction of concrete by vibration—The Registrar, The University, Sheffield (August 15).

Senior Lecturer or Lecturer (with a special interest in at least two of the following: economic or political geography, regional geography of the Middle East or Africa (especially north of the equator), and preferably a knowledge of Arabic or a West African language and experience in tropical conditions) in Geography at Ahmadu Bello University, Northern Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (August 15).

Lecturer or Assistant Lecturer (with a good honours degree in civil engineering and good general training and experience) in the Department of Civil Engineering—The Registrar, The University, Leeds, 2 (August 17).

Graduate (with an honours degree or equivalent in horticulture, agricultural science or science) in the Horticulture Division, for mushroom research—The Director, An Foras Taluntais (The Agricultural Institute), 33 Merrion Road, Dublin 4, Republic of Ireland (August 20).

Lecturer or Assistant Lecturer in Psychology at Queen's College, Dundee—The Secretary, University of St. Andrews, Queen's College, Dundee (August 21).

Second Chair of Physics at the University of Queensland, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, August 21).

Lecturer or Assistant Lecturer (with a first- or second-class honours degree, preferably in biochemistry or chemistry, with suitable postgraduate experience) in the Procter Department of Food and Leather Science—The Registrar, The University, Leeds, 2 (August 24).

Assistant Lecturer (preferably interested in plant biochemistry, physiology or cytology) in Botany—The Secretary, The Queen's University, Belfast, Northern Ireland (August 28).

Senior Lecturer/Lecturer (with an honours degree with research qualifications in botany or a related field of biology, equivalent to the Ph.D., and preferably qualifications in genetics, including cytogenetics, biometrical genetics or fungal genetics) in the Department of Botany, School of Biological Sciences, University of New South Wales—The Agent General for New South Wales, 56–57 Strand, London, W.C.2; and The Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia (August 31).

Lecturer or Assistant Lecturer in the Department of Moral Philosophy—The Secretary, The University, Edinburgh (September 1).

X-ray Crystallographer (with previous research experience of X-ray crystallography) in the Physics Department for crystallographic studies of materials at high pressures—The Secretary, Northampton College of Advanced Technology, St. John Street, London, E.C.1 (September 7).

Lecturers (specialists in one of the following subjects: (a) theory of machines, (b) strength of materials or (c) thermodynamics) in the Department of Mechanical Engineering at University College, Nairobi—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (September 10).

Lecturer or Senior Lecturer in Geochemistry at the University of Tasmania—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, September 11).

Lecturer, Senior Lecturer or Reader in Statistics at the University of Tasmania—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, September 11).

Reader in Human Genetics—The Registrar, University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne 2 (September 26).

Lecturer (with a postgraduate degree, and preferably some experience of teaching biochemistry at university level) in Biochemistry at Lincoln College (University of Canterbury), New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, September 30).

Director (with high scientific attainments in a relevant science, and preferably some experience in horticulture and administration) of the Scottish Horticultural Research Institute—The Secretary, Scottish Horticultural Research Institute, Mylnefield, Invergowrie, Dundee (October 12).

Professor of Organic Chemistry—The Registrar (Room 22, O.R.B.), The University, Reading (October 24).

Assistant Lecturer or Lecturer (or, in special cases, Senior Lecturer) in Mathematics—The Registrar, University of Sussex, Stanmer House, Stanmer, Brighton, Sussex, marking envelope "Application".

Chair of Sociological Studies—The Registrar, The University, Senate House, Bristol 2.

Chair of Zoology; a Lecturer in Zoology; and a Lecturer or Assistant Lecturer in Inorganic Chemistry or in Chemistry with a leaning towards Inorganic Chemistry at the University of Ife, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1.

Experimental Officer for the maintenance and development of complex electro-mechanical and electronic measuring devices for use in high energy nuclear research; a Senior Technician to develop new experiments for undergraduate teaching laboratories; a Senior Technician for an ionic physics research laboratory; and Junior Technicians to be trained for a variety of posts in teaching and research laboratories—The Secretary, University College, Gower Street, London, W.C.1.

Graduate Assistants (2) (preferably with experience in tissue culture methods, microscopy or serology) in a research group working on respiratory infections—The Administrative Secretary, School of Veterinary Medicine, Madingley Road, Cambridge.

Graduate Scientific Assistant, and Technicians (preferably with previous experience in the handling of laboratory animals) for interesting and varied work in the field of biological research, principally the assessment of drug safety—The Administrative Officer, Huntingdon Research Centre, Huntingdon, quoting Ref. PRN/3.

Lecturer or Senior Lecturer (with a good honours degree) in Pharmacology—The Registrar, City of Leicester College of Technology, Leicester.

Master (graduate) to be responsible for the organization and teaching of geography throughout the school—The Head Master, St. John's School, Leatherhead, Surrey.

Mathematician (with a good honours degree and a knowledge of computing) with the British Railways Board, to lead a team devising new approaches to railway control and systems analysis within the Electrical Research Division of the Board's Research Department in London (studies relating to other research within the Division will also be involved)—Headquarters Staff Manager (R.B.26/5), British Railways Board, 222 Marylebone Road, London, N.W.1.

Medical Laboratory Technician (I.M.L.T.) for Cardiological research in the Departments of Cardiology and Clinical Measurement—The Assistant House Governor, Westminster Hospital, London, S.W.1.

Nematologist (male, national of the United Kingdom or the Republic of Ireland, with an honours degree in zoology or entomology and at least one year's relevant postgraduate experience) in Uganda, to undertake a survey of the occurrence of harmful nematodes on crops, to develop techniques for testing host reactions and for controlling nematodes of economic importance—Appointments Officer, Room 301, Department of Technical Co-operation, Eland House, Stag Place, London, S.W.1, quoting Ref. RC213/183/010.

Physicist (graduate prepared to take an interest in rheology and flow measurement) to join a team engaged on research in problems of chocolate manufacture—The Director of Research, British Food Manufacturing Industries Research Association, Randalls Road, Leatherhead, Surrey.

Post-Doctoral Research Worker to investigate regulation of enzyme synthesis particularly in bacterial extracts—The Chairman, Department of Chemistry, Washington State University, Pullman, Washington, U.S.A.

Postgraduate Student to work on some aspects of porphyrin chemistry—Dr. U. Eisner, Department of Chemistry, Sir John Cass College, London, E.C.3.

Research Student (with a good honours degree in botany or agricultural botany) for work under the direction of Dr. R. K. S. Wood, on the control of plant diseases with fungicides—Dr. R. K. S. Wood, Department of Botany, Imperial College of Science and Technology, London, S.W.7.

Research Assistant in the Department of Psychology to work on human decision processes—The Registrar, The University, Nottingham.

Science Graduate to assist in developing techniques used in separating proteins in human plasma, particularly anti-hæmophilic globulin—The Secretary, The Lister Institute of Preventive Medicine, Elstree, Hertfordshire.

Senior Physicist (with experience in medical physics and electronics techniques) to be in charge of a group concerned with the application of electronics in medicine—Chief Physicist, Regional Medical Physics Department, Sheffield Regional Hospital Board, 21 Claremont Crescent, Sheffield, 10.

Senior Research Assistant in Physics to be an important member of a new group of five members and will be expected to make a lively contribution to work on electron spin resonance and relaxation in compounds which exhibit co-operative magnetism—The Registrar, The University, Sheffield.

Senior Research Associate (with a good honours degree in either biochemistry or chemistry, and have carried out postgraduate work in either subject) in the Department of Organic Chemistry, for work on the biosynthesis and structure of substances in bacterial cell walls and membranes—Prof. J. Baddiley, F.R.S., Department of Organic Chemistry, The University, Newcastle upon Tyne.

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

Scientists' Responsibility in the Atomic Age. By Prof. J. Rotblat. (The Essex Hall Lecture, 1964). Pp. 28. (London: The Lindsey Press, 1964.) 2*s*. 6*d*. [16

Ambassade de France, Service de Presse et d'Information. A Survey of Political and Economic Affairs in France, 1959–1964. Pp. 26. (London: Ambassade de France, Service de Presse et d'Information, 1964.) [16

Steel Castings Development Committee. Data Sheet No. 10: Hardenability of Steel Castings. Pp. 11. Data Sheet No. 11: Modulus of Elasticity of Steel Castings. Pp. 4. (Sheffield, 10: Steel Castings Development Committee, 13 Broomsgrove Road, 1964.) [16

The Royal Society and Nuffield Foundation Commonwealth Bursaries Scheme. Tenth Annual Report. Pp. 8. (London: The Royal Society and the Nuffield Foundation, 1964.) [16

PROBLEMS OF STATECRAFT AND THE CIVIL SERVICE

LORD BRIDGES modestly describes his account of the Treasury and its functions*, as well as the way it works, as rather prosaic, and it would be unfair to expect a book planned to give a factual account, including the reorganization of November 1962, of such a large subject to possess the liveliness of Lord Bridges's earlier lecture, "Portrait of a Profession". Nevertheless, the book has something of the charm of that lecture. It is fascinating throughout and some of its chapters, notably those on the co-ordination of economic policy, on Treasury control of the Civil Service, and on how staff control at the Treasury works, are highly pertinent to present-day discussions alike on Parliamentary reform and on the relation of the expert to the making of policy. Lord Bridges's own reflexions are limited to a short chapter of ten pages, but with the historical material, the sections on expenditure and its control and on home and overseas finance, the book is likely to remain an invaluable reference work for those concerned with the control of public expenditure or the organization of Government for years to come.

Lord Bridges's own reflexions are, as has been said, brief. Nevertheless, they are much to the point and deal with issues of the first importance at the present time. He lends the weight of his authority and experience to greater planning. This he regards as inevitable within limits, and accompanied with a transition from a yearly budget and annual estimates to a system based on a longer time unit. However, much has yet to be done before we can hope to achieve the right balance between a long enough view to permit sensible planning and sufficient flexibility to allow important changes in policy to be made quickly. On economic co-ordination, he recognizes the implications of the establishment, following earlier measures which met with varying degrees of success, of the National Economic Development Council. Here again we are very far from being able to assess the precise role that Council will occupy in our affairs and the way it will affect the work of the Treasury. Lord Bridges believes that the assumption by the Treasury of the duties of economic co-ordination means a more professional approach to budgetary problems as well as a better understanding and more effective methods of communication between the Treasury and the world of business, industry and commerce.

This in itself may lead to big changes in the way in which the Treasury works. However, while Lord Bridges welcomes this as a healthy development on the issue of management, he is directly opposed to some other proposals for reform. He regards the Plowden Report (*Nature*, **192**, 485; 1961), on the recommendations of which many of the changes of 1962 were based, as a most important and helpful document. In particular, he thinks it would have been a false step to take the management side out of the Treasury and to make it into a separate department. This, he holds, would have greatly weakened the effectiveness of both the management and the financial functions, and would have been inconsistent with the essential feature of British organization, whereby in every Department of State the responsibility for advice to the Minister on policy, finance and administration rests in the same person. It would also inevitably have led to the administration being treated as something different from, and less important than, finance. Incidentally, while accepting that some increase in specialization in Treasury work is inescapable, Lord Bridges insists that this should not be introduced in a way that will lessen the close knowledge which many Treasury officers acquire of the work done in other departments or hinder the development of relations of understanding and confidence.

In contrast to this view of Lord Bridges, one of the key proposals from a group of Fabians† for the reform of the Civil Service, and especially the administrative class, is to transfer the responsibility for personnel management and the structure of the Civil Service from the Treasury to the Civil Service Commission. This would be enlarged and include representatives from other Government departments besides the Treasury, from large employers and from the universities. It would be made responsible for all questions of conditions of service definition, of grades and categories (including pay), avenues of promotion, career planning and the making of higher appointments for which central control was desirable, the maintenance of common standard and training. One of its first tasks would be to institute a searching and independent investigation into the selection methods used for candidates to settle whether they are as unbiased and efficient as they can be made.

The Fabian group's proposals should, however, be considered against the background of the report itself. That report is the first major Fabian report on the Civil Service since the report of 1947, *The Reform of the Higher Civil Service*, most of the recommendations of which have yet to be implemented. The present report challenges the continued acceptance of the difference between management and administration, the latter traditionally embracing advice on policy, implementation of policy, Parliamentary work, co-ordination, negotiation and personnel management. While the changes since the Plowden Report are welcomed as a step in the right direction, the Fabian group does not regard them as anything like adequate. It looks for a change in the character of the staff to perform the new tasks and considers that the Service is still insufficiently prepared to provide men and resources for long-term investigations, with the result that the available expertise is not sufficiently used.

Three main characteristics of the present system attract the group's chief criticism. The system is amateur, resulting from the 'all-rounder' tradition and the belief that the administrator on the job is the best adviser on policy. Civil Servants tend to be too negative in their approach, concentrating on procedure rather than on the substance of problems and being too ready to seek compromises. Again, the system tends to be too closed and secretive in formulating policy. These weaknesses are regarded as stemming largely from the present methods of recruitment and training, the immobility, the inadequate articulation of careers and the lack of specialists at a senior level and their non-assimilation.

---

* The Treasury. By The Right Hon. Lord Bridges. (The New Whitehall Series, No. 12.) Pp. 248. (London: George Allen and Unwin, Ltd.; New York: Oxford University Press, Inc., 1964.) 30*s*. net.

† *The Administrators: The Reform of the Civil Service.* Pp. 45. (Fabian Tract No. 355.) (London: The Fabian Society, 1964.) 4*d*.

Some of these points—notably those regarding movement in and out of the Civil Service and in respect of secrecy—have been made repeatedly in various connexions as regards the organization of Government and the place of the expert in making policy. It is to meet these weaknesses that the Fabian group advances its proposals for wider recruitment, better training and more movement in and out of the Service; the fuller use of experts; the improvement of the status of professional Civil Servants as against general administrators, and some increase in their numbers; and the explicit acceptance of the need for some political appointments. On the recruitment to the Service, the group attributes the failure to recruit a larger proportion of scientists to the fact that scientists and mathematicians are attracted to posts where they can make more direct use of their subjects and where the opportunities to rise are greater, and also to the belief among graduates outside Oxbridge that there is a bias against them.

To encourage movement into and out of the Service the group advocates the institution of unified contributory pensions, with a corresponding adjustment of salaries; and secondment of staff during their careers to outside posts in local government, nationalized industry, or, subject to safeguards, private industry. It would establish for training purposes a school of administration, providing a course of two years or so, partly of work in departments and in the field, partly of study, which, combined with the greater openness of the Service, would give an attractive, first-class qualification for Civil Servants and provide some staff for nationalized industries, other public agencies and possibly private industry. With this would go the better articulation of careers so that experience was progressively widened and the provision of better and fuller courses for training in mid-career.

The Fabian group would also abolish the grading or 'class' distinction between specialists and administrators from the rank of assistant secretary upwards, giving a Senior Civil Service with equal ranks and pay, increased scope for interchange, and competition on a more equal footing for the highest posts. More specialists would be required and greater openness, so that outside study and discussion of long-range issues of policy would be encouraged, and not discouraged by excessive secrecy, and fuller use would be made of outside research. The group would also provide explicitly for two types of political appointment: experts to help implement the particular policies of the Government of the day, and personal aides to provide general help to Ministers in their private office—a proposal which Lord Bridges, in a later talk, thought most unwise.

Support for some of the Fabian group's ideas is to be found in a talk, "Intelligent Laymen in Whitehall", broadcast by Prof. Ely Devons and published in *The Listener* (**71**, 819; 1964). Prof. Devons, discussing Lord Bridges's book, questioned the apparent assumption in it that professional knowledge nearly always implied biased enthusiasm, and that, accordingly, it was dangerous to allow such experts the final say in the advice on policy given to Ministers. Prof. Devons doubts whether, without professional knowledge, the Treasury officer is competent to ask the relevant probing questions and to know whether the answers he gets are revealing and significant. He does not suggest any ideal solution to the problem of controlling and evaluating the worth-whileness of alternative projects of public expenditure, or of securing efficiency in spending. However, this plea for a closer look at the ideas of amateurism in Whitehall is one to be taken seriously and is highly relevant to the debate on science and public policy.

Prof. Devons, too, would like to see more interchange of staff between the administrative and professional, and especially scientific, branches of the Civil Service, and he reminds us of how long and persistently since the Second World War this idea has been pressed with authority. He instances, as what is possible, the increasing use now being made of economists and, pointing out that politics and public administration are not simply the pursuit of power and the reconciliation of pressure groups, but also the art of taking decisions in a state of relative ignorance, he suggests that if scientists understood this and had administrative experience, they might approach problems of policy and politics with much more sympathy than at present. It might also be added that the need to diminish this area of relative ignorance in taking decisions gives urgency to the present-day discussion on the place of science and scientists in policy making, to which Mr. S. P. Chambers's recent Chuter Ede Lecture to the National Union of Teachers (*Nature*, **203**, 227; 1964) is a notable contribution.

Prof. Devons's idea of a Senior Civil Servant as a man who, whatever his subject when he entered the Civil Service, has had experience during his career in an administrative division, a scientific or technical division, a statistics division, and perhaps even a technical costs or contracts division, clearly has much in common with the views advocated by the Fabian group as well as those which Sir Henry Tizard consistently urged. On the economics side, however, Prof. Devons has reservations to which he gave expression in a further talk broadcast on the B.B.C. Third Programme and published in *The Listener* (3, 72; 1964). In this talk, "Economic Management in Whitehall", returning to Lord Bridges's book, as well as to views expressed by Mr. Harold Wilson, Mr J. Grimond, Mr. J. Enoch Powell and by Lord Bridges in other broadcast talks, "Whitehall and Beyond", Prof. Devons suggested that we should now recognize that the major task of the Senior Civil Service is no longer administrative but managerial. He makes the distinction that the administrative type is primarily interested in seeing that the organization functions, whereas the managerial type has his eye on the trouble spots, seeking to take action in anticipation of trouble, and to see that the crucial issues of policy are faced and handled. It is, in Prof. Devons's view, the managerial approach that is needed to-day.

Prof. Devons is aware that the importance of the managerial function is already appreciated in Whitehall, and Lord Bridges's book could also be cited in evidence. While Lord Bridges refers to the advantages which new methods and techniques could bring, he comments that, in the end, men matter more than measures. While rebutting the view that managers in Whitehall should come primarily from the administrative class, Prof. Devons does not hold that professionalism and technical expertise by themselves make good managers. Both in public and private business good managers may come from those with an academic background and actual experience in arts, science, technology, economics and any other social science. The essential feature of a rising and successful manager is that he should have experience of more than one branch of the business.

It is on this that Prof. Devons bases his argument for a single-headed service beyond a certain level and would reject the Fabian proposal. He points out too that the management side of the Treasury is also the focal point for considering whether departments are appropriately organized for their functions, and that this responsibility increases in importance as the Treasury exercises less control over detail and gives more responsibility to departments. From this angle the Fabian proposal to entrust such responsibility to a reorganized Civil Service Commission seems dubious. However, Prof. Devons is no more dogmatic on such issues than is Lord Bridges, and his view that the management side of Whitehall, especially the Treasury, has much to learn from more dialogue with business on problems of organization is undoubtedly right.

The most valuable contribution of this whole series of broadcast talks is the way in which they direct attention to the crucial importance of the whole issue of management and structure to the successful development of Government in Britain. Certainly the series disposed of any tendency to rest content with the recommendations of the Plowden Report, *The Control of Public Expenditure*, and they should help to ensure that this aspect receives adequate attention in discussions on science and public policy. Moreover, Prof. Devons directs attention to an important question which was not discussed by either Mr. Harold Wilson or Lord Bridges in considering the management responsibilities of the Treasury. Those could scarcely be assessed without first considering what aspect of economic co-ordination the Treasury is competent to handle. Prof. Devons believes that the Treasury can and should look after the general level of economic activity and the balance of payments. However, he feels that there are strong arguments against expanding the Treasury and concentrating power there to deal with other important aspects of general economic policy and economic co-ordination which it does not adequately handle.

On the contrary, Prof. Devons would encourage the handling of these matters in all the other main economic departments. His suggestion that what is needed is some ordered investigation of what is taking place in the economy, as a necessary condition for initiating policy, instead of waiting until troubles become acutely obvious before dealing with them, is essentially the recommendation of the Haldane Committee almost half a century ago. Prof. Devons recognizes that this development has already started and he is convinced that this is what is needed rather than a new Ministry of Expansion or Production. He would indeed place the Economic Section and the Economic Adviser to the Government in the Cabinet Office, as they were during the Second World War and for a time afterwards, and not in the Treasury. So placed they would serve the Cabinet as a whole, forming part of the Prime Minister's staff and acting as the focal point for all central economic initiative and co-ordination.

What is particularly welcome is the whole tone of this debate. It indicates an open-mindedness and a recognition of the importance of hard, critical thinking which should be as welcome to the scientist and technologist as the unqualified support given to their claims to be considered on their own merits for the highest posts in the Civil Service. There is indeed much yet to be done, but the essential questions are being asked and the answers are being sought independently of party or prejudice. Is it too much to hope that the reform of Parliament and the relations between the Executive and Parliament and the Civil Service may be considered in just as critical and impartial a way? Certainly Mr. Harold Wilson's proposals at Stowmarket on July 3 afford some grounds for that hope. His suggestions for relaxation of the Parliamentary voting system to allow more 'free' votes and to eliminate the rigid doctrine of each vote involving an issue of confidence should receive more support from Conservatives as well as from his own supporters. Moreover, the proposal for all-party committees on the lines of the present Estimates Committee and Public Accounts Committee has something in common with what has already been recommended independently. Taken together, his proposals should go far toward restoring the authority of Parliament and easing the difficulty of attracting members of outstanding character and ability. Behind all these difficult problems of structure and organization, of advice and responsibility lies that ultimate issue stirred by Lord Bridges of men rather than measures, and that need we disregard at our peril.

IDEAS IN MOLECULAR BIOLOGY

Progress in Biophysics and Molecular Biology

Vol. 13. Edited by Prof. J. A. V. Butler, Dr. H. E. Huxley and Prof. R. E. Zirkle. Pp. vii + 328. (London and New York: Pergamon Press, 1963.) 90*s*. net.

WORKERS in the most rapidly advancing fields of research often complain of the impossibility of reading all the relevant published papers. In fact, good connexions with other laboratories, conferences and preprint circulations would often seem to reduce the published papers in one's own field to a record of priority, but there remains the problem of reading sufficiently around one's immediate subject to keep up to date with present-day ideas. The review article can be a great help here, but as the need for this type of article grows, so does the number of annual review volumes, and the more specialized become their contents. Reversing this trend, the editors of *Progress in Biophysics* have added molecular biology to their title and state that they also intend to include articles on related biochemical topics. Although it seems a formidable task to cover even briefly such wide and rapidly developing fields of research, and probably just as difficult to persuade the right people to produce the right type of review, there is no doubt that the product aimed at would be very useful.

In Volume 13, one's dependence on reviews is clearly illustrated by the thorough and valuable article of M. Grunberg-Manago on the enzymatic synthesis of nucleic acids. The number of references listed approaches 400, although this field of research only began with the discovery of polynucleotide phosphorylase in 1955. Since then, many other enzymatic systems have been reported for synthesis of RNA and polyribonucleotides, and the article considers their various roles in the *in vivo* production of the different types of cellular RNA, and the possible control mechanisms that might favour, at various stages, the production of a particular RNA, or of DNA.

The article by O. Kratky on low-angle X-ray scattering from dilute solutions of biological specimens unfortunately reproduces much that can be found in text-books—the theory of the method; ways of correcting for finite collimation; absolute intensity methods for determining molecular weights; and experimental techniques. The remainder of the article deals with some of the more recent results of the method applied to determine the molecular weights and radii of gyration of several proteins, the mass per unit length and cross-section areas of DNA and RNA, and the apparent adoption of the 3_{10} helical structure by some polypeptides in certain solvents. With one exception, all these results come from the three laboratories specializing in low-angle X-ray scattering, those of Luzzati, Beeman and Kratky. This probably reflects the caution with which many people regard the results of X-ray diffraction investigations, and a more critical appraisal of these results would perhaps have helped to stimulate other laboratories into using this very powerful technique as an available routine procedure. The article suffers greatly from a lack of sub-editing, both in readability and in misprints (a combination introducing some strange notions into Fig. 12).

A very critical review of *in vivo* investigations into the mechano-chemistry of muscular contraction by F. D. Carlson considers the published results in this field in the light of recent investigations. Whether or not one accepts the proposed scheme of events, the article is clearly useful in resolving the apparent conflict of the results of many earlier experiments by rejecting those which do not satisfy conditions which should now be applied.

Two articles review some of the recent work and ideas on the interaction of radiation with biological specimens. The first, by L. G. Augenstein, considers the various mechanisms by which energy from X-rays and γ-rays is absorbed by biological material. Recent observations indicate that energy transfer occurs at specific sites only and possible mechanisms involving excitation energy transfer and charge migration in biological systems are discussed. The second article, by G. Scholes, is concerned with the radiation chemistry of aqueous solutions of nucleic acids, their components and the nucleoproteins nucleohistone and nucleoprotamine.

The volume also includes an account by R. D. Preston of the problem of phloem transport in flowering plants, with results culled from a meeting of the British Biophysics Society in 1961. The conclusion drawn from the meeting is that organic solutes are translocated along plant stems, not by a simple hydrostatic mechanism, but by a transfer mechanism active along the whole length of a sieve tube.

CLASSIFICATION OF THE ACANTHOCEPHALA

Systema Helminthum

Vol. 5: Acanthocephala. By Satyu Yamaguti. Pp. vii+423 (85 plates). (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1963.) 450*s*.

VOLUME 5 of Satyu Yamaguti's *Systema Helminthum* concerns the classification of the thorny headed worms, a group of somewhat uncertain affinities. The division of the body into three regions, a retractile proboscis beset with spines, an often inconspicuous 'neck' and a cylindrical 'trunk', and the pseudocœlomic pattern of its structure give little indication of relationship with the round worms. Conversely, the absence of an alimentary system at all stages of development is a feature shared with tapeworms, some of which have developed the spiny proboscis as an organ of attachment. Moreover, the first larva of acanthocephalans, the acanthor, bears some resemblance to the hexacanth of the cestodes, and there are serological indications of affinity between these two groups.

However, the great systematic problem has always been to decide whether to relate the thorny headed worms with the round worms or with the flat worms, although Van Cleave proposed the setting up of an independent phylum and other writers have indicated alternative affinities with the Priapuloidea. Yamaguti takes the conservative view, defining the Acanthocephala as gonochoristic Nemathelminthes and arranging them in a single class. He has followed the scheme of Petroschenko, who divided the class into three sub-classes, but has promoted these groups to the status of orders named in 1925 by Southwell and Macfie, adding an order erected by Thapar for a single family two years later. In Yamaguti's scheme, the four orders of Acanthocephala are the Opororhynchidea (with one family and one genus), the Echinorhynchidea (with eleven families and fifty-five genera), the Neoechinorhynchidea (with four families and twenty genera) and the Gigantorhynchidea (with six families and twenty-one genera). The twenty-two families together contain about one hundred genera and more than nine hundred species, including many synonymous names. Seven families are monotypic and four have only two genera each, but six are divided into sub-families with up to fifteen genera each.

The Acanthocephala are unevenly distributed among their vertebrate hosts. The Neoechinorhynchidea occur almost exclusively in fishes, only one genus (*Neoechinorhynchus*) occurring in other hosts (an amphibian and chelonians) as well. The Echinorhynchidea are mainly parasitic in fishes, forty genera occurring in such hosts, but ten genera occur in birds, one genus in reptiles, one in mammals and three genera in various combinations of two or three classes of hosts. The larvæ of these two orders are to be found in crustaceans. The Gigantorhynchidea are mainly parasites of birds (six genera) and mammals (twelve genera) but one genus occurs in amphibians and one in reptiles, two genera in birds and mammals, and one genus in four classes of hosts (amphibians, reptiles, birds and mammals). In this group, the larvæ utilize insects as intermediate hosts. In all, therefore, fifty-nine genera occur exclusively in fishes, sixteen in birds and thirteen in mammals, about a dozen genera sharing various classes of vertebrate hosts. The only representatives of the Opororhynchidea are three species of the aberrant genus *Opororhynchus*, which are no more than 0·4 mm long and occur in American and Brazilian birds. At the other end of the size range, however, there is the cosmopolitan species which infects pigs and occasionally man, *Macracanthorhynchus hirudinaceus* (Gigantorhynchidea), the females of which may be up to twenty-six inches in length.

Some genera of acanthocephalans have been very productive of species, and a few examples serve to indicate the diversity of hosts which arises out of a predator–prey relationship. Thirty-nine species of *Neoechinorhynchus* (Neoechinorhynchidea) occur in fishes, one species in amphibians and seven species in chelonians. In the Echinorhynchidea, *Echinorhynchus* has thirty-two species in fishes, *Acanthocephalus* has a score of species in fishes and a dozen in amphibians and reptiles, *Arhythmorhynchus* has twenty-five species in piscivorous birds, *Polymorphus* twenty-six species in birds, occasionally mammals, and *Corynosoma* has thirteen species in aquatic birds and twenty-two species in mammals. In the Gigantorhynchidea, *Centrorhynchus* has fifty-seven species in birds, mainly raptatorial forms, and five in mammals, *Prosthenorchis* has only one species in birds but nineteen in mammals, especially monkeys, and *Prosthorhynchus* has only two species in mammals but a score in birds. The nine genera together contain more than three hundred species, and at least one-third of known species.

These and many other interesting features concerning the spread of acanthocephalans in the animal world can be gleaned from Yamaguti's most recent survey. Nearly one thousand references will guide investigators through the maze of available information on the group, and more than eight hundred clear line diagrams (the best which have appeared in the *Systema Helminthum*) will also serve. Information concerning size has sometimes been omitted from the volumes of this, series but this criticism no longer applies; size criteria are given liberally for adults, eggs and other characteristics and for the majority of species, even when these are numerous in a genus. There are many references concerning experimental infections and information concerning larval forms and intermediate hosts in excess of what could be expected in a systematic essay, and a good general account of structure by way of introduction. In short, the blemishes noticed in preceding volumes have been avoided in this volume, although a few typographical errors are evident. This is not surprising in view of the plethora of phantasmagorial names such as *Acanthocephalorhynchoides ussuriense*, and an occasional lapse, such as in '*Arythmorhynchus*' (p. 395) and '*Gigantorhynchus*' (p. 404), is pardonable. The names of authors provide their own typographical problem, but it is odd to find, closely following a tribute to dedicated bibliographers working in the Catalogue Room at the Beltsville Parasitological Laboratory, that Yamaguti is indecisive and recalcitrant about the spelling of the name Petroschenko, which appears thus in the Index-Catalogue. At the same time, we have to thank Yamaguti for a sustained attempt to present scientific names accurately and a determined effort to provide a reliable taxonomic scheme, which at best can only be provisional. It is to be hoped that readers will realize how often and with what magisterial serenity Yamaguti had adjudicated in the face of difficulties created by writers who produced imperfect and defective work. It is a lamentable fact that much bad workmanship is evident in the original literature on the systematics of helminths and perhaps the greatest value of Yamaguti's great efforts will lie in the direction of better descriptions of species and genera in the future than have often been forthcoming, with more emphasis on the range of their variability. A taxonomic scheme will be as reliable as the work of the taxonomist and no more reliable, and with this admonition to the would-be systematist in the field of parasitology we can leave Yamaguti's *Systema Helminthum* in what we hope will be good hands.

CALCULATIONS IN COMPLEXOMETRIC ANALYSIS

Complexation in Analytical Chemistry

A Guide for the Critical Selection of Analytical Methods Based on Complexation Reactions. By Anders Ringbom. (Chemical Analysis: a series of Monographs on Analytical Chemistry and Its Applications, Vol. 16.) Pp. x + 395. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1963.) 113*s*.

COMPLEXATION reactions are now widely used in analytical chemistry and it is not unusual for the analyst to have to choose between several complexometric methods of analysis and for him to have difficulty in selecting the method which will give the most accurate result. Alternatively a method may need modification to suit the particular circumstances of the analysis. Such problems are frequently resolved as the result of a series of inconclusive experiments, or by the personal prejudice of the analyst, as insufficient time is available for a more complete investigation. A rapid, less empirical, approach has been long overdue.

In *Complexation in Analytical Chemistry* Ringbom shows that an increased application of theoretical principles to chemical analysis—in particular to complexation reactions—can greatly assist the analyst in making rapid and accurate decisions concerning the choice of analytical procedures. A simple mathematical treatment of equilibria is presented and this enables the analyst to establish the optimum experimental conditions for complexation reactions. Existing methods of analysis can be compared for determining their relative accuracies. Errors caused by various side reactions can be estimated and ways of reducing or eliminating the interferences can be quantitatively studied. There are also interesting possibilities of developing new methods for solving special analytical problems.

The mathematical treatment is lucidly explained and illustrated by more than a hundred examples. Analysts, once they understand the basic principles on which the calculations are based, should have no difficulty in making such calculations, as may be necessary, to assist in solving particular problems.

Complexation reactions are treated in their broadest sense, chapters being devoted to titrations, masking, acid-base reactions, ion-exchange, metal extraction, electrochemical reactions and photometric techniques. Actual methods for particular analyses are not given as the object of the book is to enable the analyst to devise these for himself and no attempt is made at reviewing the literature on complexation reactions in analytical chemistry. An extensive appendix, more than one-fifth of the book, contains details of equilibrium constants and other useful values abstracted from the literature. Notwithstanding the extent of the appendix, the main limitation to this simple mathematical approach to complexation reactions is the lack of the relevant equilibrium data for many reactions of interest.

The book is well produced and the text is clearly arranged; but it seems unfortunate that a work which is intended to assist the analyst in solving everyday analytical problems could not have been more attractively priced.

J. R. COOKE

AN ENCYCLOPÆDIA OF INORGANIC ANALYTICAL CHEMISTRY

Methods of Quantitative Inorganic Analysis

An Encyclopedia of Gravimetric, Titrimetric and Colorimetric Methods. By Kazunobu Kodama. Pp. xiv + 507. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1963.) 160*s*.

A NUMBER of works on inorganic analytical chemistry, often running to several volumes, have appeared in recent years to meet the demand of analysts for organized compilations from the original literature. This present treatise, *Methods of Quantitative Inorganic Analysis*, represents an interesting and generally successful attempt at compressing a wide range of detailed material within the compass of a single volume. Dr. Kodama has achieved this difficult task by efficient arrangement of material and by adoption of an abbreviated style reminiscent of that of *Chemical Abstracts*. Theoretical discussions and diagrams of apparatus have been omitted and there has been some sacrifice of typographical clarity. However, there are some fifty-nine tables where a great wealth of varied and analytical data is clearly and concisely presented.

Originally, the author intended this treatise to cover a wider field than that now presented but limitations of space have precluded any treatment of purely physical techniques such as spectrographic, X-ray fluorescent, radiometric methods, etc. The scope of *Methods of Quantitative Inorganic Analysis* is exactly described by its sub-title: *An Encyclopedia of Gravimetric, Titrimetric and Colorimetric Methods*. However, where flame photometry is an important method of analysis references are given to the pertinent literature, but polarographic methods which are valuable in metal alloy analysis are given no mention.

The book is divided into three parts, each representing a different and complementary aspect of inorganic analysis. For a particular problem it will often be necessary for the analyst to consult and combine material from each part.

Part 1 covers the field of general analytical techniques. An informative chapter on the decomposition of solid samples includes a table showing the percentage loss of volatile elements during acid attack. Another chapter comprehensively surveys the fields of complexometric, iodometric, acid-base and redox titrimetry; the properties of a wide range of indicators are presented in several tables. There are brief chapters on gravimetry, electrodeposition and optical methods.

Part 2 includes a detailed and comprehensive survey of the many organic reagents now in use in gravimetric and colorimetric analysis. Structural formulæ of many reagents and metal complexes are given which will be of assistance to the analyst not well versed in organic chemistry. In addition, there are useful chapters on ion-exchange, chromatographic and solvent extraction techniques. As is the case throughout this work the text is augmented by many tabulated data.

The arrangement of Part 3, the main section of this volume, follows the classical scheme of group analysis and each chapter is devoted to one element or group of similar elements. Chapters are subdivided into sections on attack, separation and determination. Treatment is comprehensive but selective, as methods are enumerated in order of analytical importance, preferred methods often being indicated; this is a useful feature for the analyst who has little time for method investigation. Systematic schemes of analysis are not neglected and many are presented in lucid diagrammatic form and include the analysis of silicate and fluorosilicate materials, the platinum metals, rare earth and uranium minerals. The needs of an analyst confronted with a wide range of analysis are fully met, only the analytical chemistry of the transuranic elements being neglected.

Numerous references both to standard works and to original papers are given at the end of each chapter and with many of the tables. There is an extensive index, and clarity has been enhanced by separation into two sections—one general and one devoted entirely to organic reagents.

The author has drawn heavily on such authorities as Hillebrand and Lundell, Schoeller and Powell, Fresenius-Jander, Sandell, Welcher, etc., and this book can be regarded as an omnibus digest of these works supplemented by methods from the original chemical literature up to 1957. This treatise is therefore comprehensive and authoritative, but there has been considerable delay in publication due to checking and correction. There are a few minor errors in the text.

This work will undoubtedly appeal both to the research and routine analytical chemist. The encyclopædic nature of this work makes it useful for reference, but, above all, this is a book for the inorganic analyst to have on his bench as a practical working manual.

A. D. WILSON

TEXT-BOOK OF ACOUSTICS

A Course of Lectures on the Theory of Sound

By S. N. Rschevkin. Translated from the Russian by O. M. Blunn. Pp. xv+464. (Oxford, London, New York and Paris: Pergamon Press, 1963.) 84*s*.

AT a time when there is a tendency to play down acoustics in physics departments of universities, it is interesting to observe the material presented in this subject to students specializing in acoustics in the Faculty of Physics of the University of Moscow. The impression is gained that the presentation is much more extensive and detailed, and therefore better drill, than in Britain. Thus the 450 pages of *A Course of Lectures on the Theory of Sound*, as compared with existing fundamental books on acoustics (for example, P. M. Morse's now classic *Vibration and Sound*), are easy to read through and form a good introductory text-book on the theory of sound. There are also occasional practical touches to the book which will endear it to applied acousticians; numerical examples are worked into the text from time to time to show the physical orders of magnitude involved, and the treatment of lumped acoustic impedances and acoustic waveguides is carried through in enough detail to make the methods and results readily accessible to those not primarily interested in the theory for its own sake.

The book is not, however, a comprehensive text-book on all aspects of acoustics, being confined almost entirely to problems of sound transmission and radiation. Nothing is said about such broad subjects as room acoustics, aerodynamic noise (apart from some reference to Gutin's propeller noise theory), nor about physiological acoustics. These omissions make it incomplete as a technological text-book. Regrettably, therefore, it is not the answer to the often heard prayer for a complete modern text-book of acoustics.

There are several things about the treatment which might well be taken up in British presentations. For example, the confusion that can arise from following Lord Rayleigh's tradition of commencing with the vibrations of strings and membranes is overcome by eradication of these topics, and the whole subject is developed immediately from the hydrodynamic equations. The traditional method is dear to the hearts of most physicists, of course, but in those unfamiliar with wave motion it can easily create the impression that standing wave motion, rather than travelling wave motion, is the basic ingredient of sound.

The book is well written and translated, the adherence to the symbolic notation used in the Russian edition doing surprisingly little to detract from its value. To sum up, it is a good book for those desiring an extensive treatment of the basic elements of acoustic transmission and radiation theory and, as such, it will undoubtedly be useful to students of acoustics, filling the gap between existing elementary and advanced works. It fits into present engineering courses in Britain on acoustics as a reference book, however, rather than as a principal text-book.

E. J. RICHARDS

POLITICAL TRANSGRESSION OF THE PACIFIC

The Western Invasions of the Pacific and Its Continents

A Study of Moving Frontiers and Changing Landscapes, 1513–1958. By Dr. A. Grenfell Price. Pp. viii+236+11 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1963.) 35*s*. net.

SIR GRENFELL PRICE has chosen a huge canvas—the largest and deepest of oceans and its contiguous continents, the land-mass of Asia, North and South America and Australasia and peoples as remote from each other as the Eskimos and the Maoris. He spans four centuries, from the invention of the lateen sail which enabled European invaders "to sail close to the wind and avoid the dangers of lee shores" to the present redrawing of the political map.

It would have been a big enough task for any historical geographer to reassess the motivations and impact of the Portuguese, the Spaniards, the Dutch, the British, the French and the Russians as conquerors, sojourners and settlers. This Sir Grenfell Price has done with an insight, illumined by the political events of our times, and with an objectivity which will not make it 'recommended reading' in emergent countries which do not count themselves as beneficiaries. That is a pity because, as the heirs of the empires, it might help them to evaluate their inheritance.

But *The Western Invasions of the Pacific and its Continents* goes much further. It deals with the landscape, which was changed by the colonial transfers of exotic plants for industrial crops and plantation agriculture (as well as the ravaging of flora and fauna); with the transfers of people, not only of the European settlers but also of the alien labour whom they imported and who, in many places and with present embarrassment, are now outnumbering the indigenous population; with the geography of disease and with the population explosion.

When we speak to-day of the great benefits which modern (Western) medical services and medical sciences have conferred on Pacific peoples, it is well to remind ourselves (as the author does) that the most dangerous exports of the Western world were small-pox, measles, pulmonary diseases, malaria, filariasis, hookworm, leprosy, maybe syphilis and certainly gonorrhœa, which decimated indigenous peoples who had no immunity.

On population distribution and redistribution, the book is less convincing. Australia, with the swarming millions of Asia too close for comfort, is compared with Canada (6 per square mile) and Asian Russia (2 per square mile). By deducting the arid lands and the tropics, Australia has 720,000 remaining out of 2,900,000 square miles, which gives 14 (whites) per square mile. But there can be argument even about that subtraction. "Unsuitable for settlers" depends on what sort of settlers and whether lands can be made suitable. After all, the whole story of man is one of mastering his environment. Nor is it better than a debating point to say that Australia is taking the majority of migrants from some of the most crowded countries on the Earth—Britain with 540 per square mile, compared with India with 293; the Netherlands with 839 per square mile, compared with Japan with 610; and Italy with 413 per square mile, compared with Indonesia with 139. He makes the point that the 'white policy' of the U.S.S.R. in its Asian territories and the inviting sparseness of Siberia, just north of expanding China, "will require a solution one day": *verbum satis sapienti*.

He has a case, however, for arguing that countries now looking enviously at open spaces might look at their own. Indonesia, with Soekarno clamouring for *lebensraum*, has a population of 700 per square mile in Java, 70 in Sumatra and 7 in South Borneo. The sensible plans operated by the Dutch for resettlement have been conspicuously unsuccessful under his régime.

This is an invaluable book for those who want to see the imperial past, without romance or recrimination; who want to understand what is behind the crisis headlines and who want to be sensible about the future.

RITCHIE CALDER

TROPICAL METEOROLOGY IN AFRICA

Tropical Meteorology in Africa

Proceedings of the Symposium Jointly Sponsored by the World Meteorological Organization and the Munitalp Foundation. Edited by D. J. Bargman. Pp. xv + 446. (Nairobi: Munitalp Foundation, 1960. Available from the World Meteorological Organization, Geneva.) 20 Sw. francs; 33*s*. 3*d*.; 4.70 dollars.

WHILE the *Proceedings* of a symposium, published some years after the event, may sometimes represent an unnecessary record of material which is either ephemeral or already on record elsewhere, this is certainly not true of the Nairobi symposium on tropical meteorology in Africa. Under the joint sponsorship of a United Nations specialized agency and an independent research foundation, tropical meteorologists attended from twenty-one African countries, as well as from Belgium, Britain, France, Germany, Spain and the United States; and the record of proceedings, despite a few typographical and linguistic lapses, reflects part of a unique background of collective professional experience, much of which has still to reach the literature.

There were a number of authoritative and valuable reviews of the problems and methods of tropical meteorology in general, but special attention was naturally directed to new findings specifically concerning Africa. These may perhaps complement some of the earlier post-war progress in tropical meteorology, which was based predominantly on data 'climatically insular' rather than continental. In particular, while fully recognizing the continuing need for better observational cover, the symposium unanimously accorded a high priority to further work on new synoptic models. This need was also the main theme of the 1964 presidential address to the Royal Meteorological Society, which posed, as the central problem of meteorological analysis in general, the fact "that the rapidly increasing amount of meteorological data which is being collected will not be properly put to use—indeed part of it may not be used at all—unless an adequate system exists to collate and present it in a form which can be readily understood and digested". At the Nairobi symposium, special interest centred on the progress in this respect reported by Johnson and Mörth, establishing in eastern Africa relationships between equatorial weather and typical flow patterns in the middle troposphere; and visiting meteorologists were particularly impressed to see these ideas already incorporated into present-day forecasting practice. Furthermore, this work, utilizing the additional upper-air data which became available during the International Geophysical Year (and incidentally supported by one of the few Colonial Development and Welfare schemes in tropical meteorology), demonstrated for the first time a series of systematic relationships between winds and contours of isobaric surfaces in the equatorial belt. This is a long-standing problem of the general circulation, to which attention was also directed by the work of Cochemé in the same region.

Another subject on which potentially classical results were first presented in detail at this symposium was the energy-balance of tropical land surfaces. Pereira and McCulloch described catchment-area experiments in which continuous direct measurements were made of all the more important factors in the heat and water balance over complete valleys, varying in extent from sixteen hectares to eight square kilometres. From these results, together with heat-flux analyses over bare soil and water-use studies of grasses and crops, measured values were presented for a representative sample of land-surface conditions, ranging from the warm and semi-arid plains of central Tanganyika at an altitude of 1,000 m to bamboo mist-forest up to 3,600 m in the Aberdare mountains of Kenya. The importance of these data, as a contribution not only to applied meteorology but also to the physical basis of the science, was emphasized by Prof. Flohn—whose presentation of his own analyses of climatological data from Africa and the adjoining oceans, undertaken in such a manner as to provide significant information on synoptic-scale phenomena, was strongly approved by synoptic meteorologists present.

Space does not permit mention of other significant lines of work reported, on meteorology and on its applications to African problems. A final point, which is perhaps of some interest in relation to the organization of such symposia in general, is the effectiveness with which technical discussion was stimulated by a relevant and extensive travel programme, including, for example, the agricultural resettlement schemes of the Aberdare catchments; the Murchison Falls, with their fantastic associated wild-life probably still much as Samuel Baker saw it a hundred years ago; and the Owen Falls dam, where the scale of the combined uncertainties both of the total rainfall over Lake Victoria, and of evaporation losses from its surface, is still of the same order of magnitude as the resulting flow of the Nile.

Clinical Toxicology of Commercial Products

Acute Poisoning (Home and Farm). By Marion N. Gleason, Robert E. Gosselin and Harold C. Hodge. Second edition. Pp. xv+1211. (London: Baillière, Tindall and Cox, 1963.) 176*s*.

Clinical Toxicology of Commercial Products consists of eight sections, separately paginated and each printed on differently tinted paper, but bound together as a single book. Section 1 (pp. 15) relates to general first-aid and emergency treatment in the event of acute chemical poisoning, both before and when medical aid becomes available. Section 2 (pp. 141) is an index to the active ingredients of some 3,000 proprietary and other substances; toxicity ratings from 1 to 6 (practically non-toxic to 'super-toxic') are ascribed to the principal chemicals included, while broad classes of compounds are identified with one of 77 specific congeners, these being separately indexed with toxicological details, symptoms and treatment in Section 3 (therapeutic index, pp. 157). General remedial measures, from respiratory aids to nutritive support, are considered in Section 4 (pp. 76), which is followed by a large index (Section 5, pp. 674) of more than 14,000 trade names of products which might be ingested, either accidentally or suicidally. In this the principal toxic constituents are identified by an asterisk, though in practice such might number as many as (say) five of a total of seven listed ingredients. Cleaning fluids, pesticide formulations and sedative tablets all feature prominently; entries, most of which are American proprietaries, range widely, from 'Lifebuoy Soap' to 'Kitty Chaperone' (keeps cats off furniture). Formulations are indexed by function in Section 6 (pp. 113) and by manufacturer in Section 7 (pp. 22). The final section (pp. 13) is a provisional classification of chemicals which either have proved, or may prove to be, poisonous in man, with a numerical ætiological assignation; the latter is an extension of an existing classification and, as such, a contribution to the rationalization of the subject, despite many necessary compromises.

There is no suggestion that this large volume is an emergency ready-reference volume. It could be used as such only after familiarity with the basic plan has been acquired, when (as in other circumstances) the initial logical sequence of consultation might be to Sections 5 (or, failing this, 6), 2 and 3. Such an approach, with a somewhat extended explanation, is set out diagrammatically as the frontispiece. As a reference source-book there is no doubt of its value, the main limitation to which in Britain lies in the fact that the proprietaries are mainly of North American origin. H. Egan

Progress in Chemical Toxicology

Vol. 1. Edited by Abraham Stolman. Pp. xii+436. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1963.) 14 dollars.

This book, the first of a continuing series of volumes covering developments in chemical toxicology, is divided into eleven somewhat unevenly balanced chapters. For example, the chapter by Rieders on "The Determination of Antiarthritics, Antihistamines and Thymoleptics" occupies 7 pages, whereas "Narcotics and Related Bases" by Farmilo and Genest covers 87 pages. I should have thought that with a more consistent classification (either pharmacological or analytical classification, but not both) of chapters, the 7-page chapter could have been incorporated in one of the other manuscripts.

Chapter 1, by Freimuth, briefly describes isolation and separation techniques for identification of poisons. Then follows a chapter by Goldbaum, Schloegel and Dominguez on the application of gas chromatography to toxicology. Aliphatic alcohols are thoroughly covered by Harger and Forney, and Curry, in a well-written and informative chapter, discusses the analysis of acidic and neutral poisons. There is a useful chapter by McBay and Algeri on ataraxics and non-barbiturate sedatives. Feldstein deals effectively with the toxicity of, and analytical methods for, air pollutants. Tyler contributes 43 pages on poisonous mushrooms, and Schwarting concludes the volume with a chapter on poisonous seeds and fruits.

It is a pity that this volume should have taken such a long time before its final publication. I am aware that one of the contributors sent his manuscript to the editor early in 1962. The editor's preface is dated August 1963. The book appeared in 1964. I feel that neither the editor nor the publishers are to be blamed for the delay, and that this is due to the lack of a sense of urgency and complete co-operation on the part of one or some of the contributors. A book of this type is of greatest value when the date of its appearance is as close as possible to the date of publication of the papers on which the various chapters are based. Some way of dealing effectively with procrastinating contributors should be devised.

Otherwise, part of the volume is a useful compilation of some of the advances which have taken place in chemical toxicology in recent years. H. V. Street

Meristems, Growth and Development in Woody Plants

An Analytical Review of Anatomical, Physiological and Morphogenic Aspects. By J. A. Romberger. (U.S. Department of Agriculture Technical Bulletin, No. 1293.) Pp. vi+214. (Washington, D.C.: Government Printing Office, 1963.) 1.75 dollars.

In this monograph the author, as his sub-title indicates, has attempted to give an account of aspects of the morphogenesis, anatomy and physiology of selected gymnosperms and woody angiosperms. His approach thus combines in a useful manner the classical methods of anatomists of an earlier period with those of contemporary investigators of plant morphogenesis. It is valuable to have the several accessions of information brought together, briefly but in sufficient detail, in one volume—the book is primarily intended for students of physiology, horticulture and forestry—though, unavoidably, there are repetitions of facts and concepts that have received wide publicity in recent years. The general objective, maintained throughout, has been to relate growth, development and the functional activities of organs to the physiological processes in main and lateral shoot meristems (and also in other meristems, for example, roots) from which they all originate.

In the section dealing with anatomy and 'physiological morphology', a useful range of information, some familiar, but some less familiar, is clearly and fairly presented and discussed. In other sections, the episodic growth and dormancy of shoots, and the physiological processes that are, or may be, involved, are discussed in some detail, with reference to *Pinus sylvestris* and selected woody dicotyledons. In this section the phenomena of photomorphogenesis, Circadian rhythms, endogenous growth regulators, etc., are critically examined. A final section provides a useful account of episodic growth and dormancy in roots. The author, whose attitude is one of moderated scepticism, has properly been the critic of his own efforts and of the contemporary state of botanical science as he sees it. As he notes in his retrospective survey: "The reader who expects a pithy summary, replete with sweeping truths about the behaviour of meristems, the control of growth and development, and the physiological basis of dormancy, will be disappointed". Quite simply, botanical science has not yet reached that point. But, as the present volume indicates, many avenues of approach to the central problems are now being explored, and progress, though often fragmentary and highly incomplete, is being made.

The book, which is clearly and succinctly written, sometimes in a provocative but agreeable style, is modestly illustrated and well produced. C. W. Wardlaw

MONEY FOR RESEARCH AND RESEARCH FOR MONEY*

By Dr. ALAN T. WATERMAN

Chairman of the Board of Directors, American Association for the Advancement of Science, and former Director of the U.S. National Science Foundation

THE Michigan Association of the Professions appears to be a unique organization. Out of curiosity I looked up the word 'profession' in Webster's dictionary and was very amused. I find there are two major meanings: a profession may be either that which one professes, or that about which one professes to have knowledge. (Incidentally, one meaning of 'profess' is to pretend to have knowledge.) I conclude that, according to the dictionary, membership in a profession may have a very broad base. But, curiously, of all the professions there is only one which entitles a person to be a professor. (Again incidentally, the dictionary defines a professor as one who publicly teaches any science or branch of knowledge—which puts science in its place!)

However, I was finally reassured to find that a profession is a collective body of persons engaged in a calling, which serves the present purpose.

As has often been said, money is not everything but it surely helps. Its importance is attested in many of our sayings. In fact we might make an intriguing combination of a couple of these: 'the root of evil is that which makes the world go ' round'.

Money is certainly essential for modern research, and it is no secret that research can be a money-getter. For my part I have found that the progress of research has been chiefly retarded by two groups: (*a*) those who want to withhold money from research, as a foolish and unnecessary expenditure; (*b*) those who believe research can do anything if enough money is put into it. Curiously, it is the latter group which is frequently the chief source of ammunition for the former. If outlandish claims were not so often made in the name of science, there would be fewer arguments against the progress of research. All of which should indicate that one of the most constructive moves we can make is to bring about better public understanding of science.

When one separates the topic as I have done into money for research and research for money one does two things—one separates two important and different objectives of research and at the same time one can resolve much of the argument which occurs in justifying research for budgetary purposes.

The first of these objectives for performing research states that research is important in its own right. This is a point of view found especially in academic environment. In its pure form it holds that 'to seek the truth' is one of the highest pursuits man can follow, and no further justification is required. Essentially basic research does that; it is merely a modern and highly sophisticated technique for seeking the truth, namely, knowledge and understanding of man and the world he lives in. Why is that important? Well, research, and especially research in science, has been largely responsible for progress in human thought and philosophy. It has had much to do with exploding superstitions and removing that greatest fear of all, fear of the unknown, and has made noteworthy advances in our thinking, to say nothing of broadening our outlook on the world we live in. It puts emphasis on the higher things in life, much like a religion. But one can scarcely put a precise money value on it, nor are its advocates inclined to do so.

The second objective takes a practical and realistic view. Essentially it says of the first: 'For those who like that sort of thing, it is just the sort of thing they like', but so what? There is no particular harm in carrying out research for its own sake. If anyone wants to spend his life collecting butterflies or cosmic rays or satisfying his curiosity by looking through a microscope or telescope, that is his business. After all this is a free country where we allow such activities to go on, which is more than some other countries do. But no sensible citizen would expect to contribute funds for such a purpose, except as we do for symphony orchestras, art museums, etc., perhaps as a matter of civic pride, or as we provide toys for children. Public money? Certainly not. Hard-earned dollars should go in quantity only to programmes and projects where the practical need has been demonstrated, where there is every likelihood of a financial return, or, failing that, where some practical accomplishment can be made, such as the cure of a disease, the production of a superior military weapon, or the improvement of traffic conditions. Occasionally there are other practically important projects, too, such as desalination of sea-water or a remedy for air pollution.

According to this school of thought all research should be planned for, and judged by, its practical value. It may originate from awareness of needs—national, commercial or private—and materialize in the form of proposals for research to meet these needs. Or it may go a bit further, as occurs more and more in our technology, and support research which might open a new market, directly useful then for making money, and indirectly for raising standards of living.

But let us pause for a minute and see how much money is now going into what kinds of research, and who is providing it.

This is a subject which has received an increasing amount of attention, and properly so, on the part of industry, the U.S. Federal Government and economic analysts. In its entirety it has come to be called science and technology. Science enters as the discipline or study—the profession if you like—which seeks to explore the unknown, to discover new facts, new phenomena, or new techniques either to make further advances in knowledge or to show the possibility of useful application. Thus science is commonly understood to include all basic and some applied research. Technology seems to be the best term we can find to take in the entire gamut of what it takes, from the technical point of view, to bring about economic strength, prosperity, military security and general welfare. Thus it commonly starts from science as its technical base and includes, especially, applied research, engineering development, test and evaluation, production, distribution and use.

For present purposes we need merely note that the analyses on the subject are chiefly concerned with research and development and with man-power.

The national total for research and development in the United States is at present estimated at about 15 billion dollars†. This is about 2·5 per cent of the gross national product, an increase from 1·4 per cent 10 years ago. Of this the Federal Government provides about 65 per cent, while about 32 per cent is provided by industry. Thus industry and the U.S Federal Government are paying practically the entire research and development costs in the ratio of 1 to 2.

---

* Substance of an address before the fifth Annual Congress of the Professions held at Lansing, Michigan, during February 7–8.

† 'Billion', a thousand millions in the U.S.A., France, etc.; in Britain, Germany, etc., a million millions.—Editor.

In this national effort, industry is doing most of the work. Seventy-four per cent of the total funds are used by industry in performance of research and development, 14 per cent by the Federal Government in its own laboratories, and 12 per cent by non-profit institutions.

The distribution of scientific and technical man-power among these economic sectors is similar. Thus of the total number of scientists and engineers employed in research and development activities in 1960, 68 per cent were in industry, 15 per cent in the Federal Government, 12 per cent in academic institutions, and the rest in other, non-profit institutions.

Although the total national funds for research and development have about tripled since 1953, this distribution of funds and scientific and engineering man-power has changed very little, and practically not at all since 1957. During this period the labour force has increased by 15 per cent, and scientific and technical man-power by 57 per cent. As a percentage of the labour force, scientific and technical man-power now stands at 3·6 per cent; it was 2·5 per cent in 1953.

The distribution of efforts in basic research is somewhat different but it is similar in its stability. National funds for basic research at present amount to nearly 1·5 billion dollars, which again is about three times the amount in 1953. As a percentage of the total funds for research and development, basic research funds remained nearly constant at 8 per cent until the past two years, when they rose to about 10 per cent. This largely reflects costly new projects in such subjects as oceanography, high-energy accelerators, and space research, where research facilities are especially expensive. The Federal Government is the source of less than 60 per cent of national funds for basic research, industry about 25 per cent, while academic and other non-profit institutions provide the remaining 15 per cent, in the ratio of about 2 to 1.

Colleges and universities have consistently performed nearly one half the nation's basic research, industry about one-third, and government about one-sixth.

What is especially important to note is that the American nation's effort in research and development has been a remarkably consistent one in its distribution of funds and technical man-power for the past decade. In recent years, increasing apprehension has been voiced over the large increases in the Federal budget for scientific research and development. While these increases have indeed been large, it should be noted that they have been quite effectively matched proportionally by the increases in contributions from the other sectors of the economy. Of particular significance is the fact that the Federal Government is not acquiring a monopoly or control over scientific and technological activities any more than it has been exercising for the past decade. In view of this stability in distribution of effort, it would seem that one should proceed with caution in the formulation of any radical change. Obviously such could lead to serious dislocations and loss of valuable time and effort in the process. This we cannot afford, for we must never forget that we live in a highly competitive world, and the modern key to successful competition lies in science and technology.

Now how does this analysis relate to my topic? In the first place, the figures I have given cover research, development and man-power. Since we are concerned here with money, it is logical to include development, since it is development which bears most of the cost and not research. In fact, research, both basic and applied, accounts for only 30 per cent of the total effort; basic research for only 10 per cent.

At this point I am somewhat in a quandary, since the theme here is research, not development, whereas most of the money involved goes to development and not research. The two are not the same, and the failure to make this distinction is responsible for much confusion and concern. Generally speaking, research is relatively inexpensive; it is at the point of decision to undertake engineering development that one has to face the commitment of large sums of money. The distinction is simple enough in principle: research, whether basic or applied, is exploratory in nature. It tries to find something new scientifically or to establish the feasibility of a development in principle, not in practice. Development starts from the premise that a practical undertaking may be feasible and attempts to work out and perfect a device or process suitable for production. Since the particular objective of development is known and understood, the decision whether to initiate development or not, though often difficult, is more clear-cut, and since it involves large sums of money and extensive employment the decision must be examined with great care. The whole affair may be likened to the opening of a new territory. The comprehensive exploration of the territory corresponds to basic research, the search for mineral or other resources corresponds to applied research, and the examination of how these resources may be exploited corresponds to development.

In proceeding further with this matter I shall touch briefly on considerations relating to development and then go into the subject of research somewhat more thoroughly.

For the most part, development has money as its fundamental objective. It is carried on in typical fashion by the technical industries in the hands of which it has reached high standards of quality and efficiency. Development financed by Government cannot, of course, be said to have a profit motive in the same sense, namely, profit to the financing agency. But it may carry a reasonable return to a profit organization under contract. Apart from that, as in the case of military development, it may be said to provide a form of national insurance. In any event, if conducted wisely it has value in strengthening the national economy. Because of its relatively high cost, special attention should be directed to the criteria for undertaking developmental projects. Thus in making a decision regarding a particular developmental project, one could consider: (1) What are its objectives and what are their relative priorities as compared with other objectives? (2) Will the programme if successful meet these objectives? (3) Is the programme technically feasible? (4) Is the estimated cost of the effort justifiable in money, man-power and facilities? The operating agency should be held strictly responsible for making these decisions wisely.

On the other hand, most basic research belongs in the first category—it requires money rather than produces it. Occasionally basic research is required in association with development to remove bottlenecks or to provide essential background. Some applied research and development belongs in this category, too, like the engineering development of elaborate instruments or installations for scientific purposes such as high-energy accelerators, radio telescopes and instruments for the study of outer space. These are not primarily concerned with making money, but money is required for their prosecution. As research in science becomes more complex and sophisticated the financial outlay begins to assume larger and larger proportions. As a result, money for science and basic research in particular begins to compete with money-making research, with research aimed directly at meeting pressing needs and resolving critical problems.

Dr. Vannevar Bush pointed out a consequence of this situation in the terse observation that applied research drives out basic—a sort of Gresham's law. Thus, in the face of the inevitable budget limitations, available funds go to programmes which are immediate and critical and to research projects the usefulness of which can be clearly foreseen and justified. Basic research does not fall in this class since it works in the unknown and cannot predict with any certainty whether its findings will be significant, much less whether they will be useful. In fact, one definition of basic research is research for which one cannot secure money!

In view of this competition for funds and of the extraordinary increase in research and development activity, what should our policy be?

If we are forced to economize in science and technology then we should give maximum care and attention to where most of the money is going—namely, development. As for research, we should encourage applied research and expect that industry and government will support basic research which underlies specific important practical objectives. But this is not enough. In fact, to adopt this criterion exclusively is most short-sighted and dangerous. As history amply records, most of the epoch-making discoveries have come from research with no other aim than free exploration of the unknown. How could one have planned for discoveries such as X-rays, radioactivity and antibiotics when they were not known to exist?

As a matter of fact, this type of pioneering research should be regarded and justified as an investment. It should be comprehensive in scope and cover all areas of science. It should include all degrees of promise—from projects of slow but certain progress to difficult and speculative projects which if successful would yield a high return, scientifically or practically. In planning such a programme one must count heavily on the experience and competence of individuals and groups to be supported, since they are the experts in this type of exploration and are thus best able to decide on promising leads. The investment when planned and executed in this way is statistically certain to yield results; in any event results of scientific value, but also practical results which more than pay for the cost of the investment, as the technical industries well know. It may be that the individual who makes a scientific discovery does not see a practical application or does not choose to proceed with one. Perhaps a series of basic research findings are necessary before an application emerges. But, as history also abundantly proves, the findings of science generally find their way into useful application.

The conclusion I would draw concerning the major question I have raised is that there should be no real conflict between the pursuit of free basic research and that of applied research, aimed at development. We must actively support both—basic research as an investment to explore the scientific and engineering frontiers and open new potentialities for technology, and applied research to investigate the feasibility of these findings and to search for answers to our pressing technical problems. The latter will often bring a direct money return. It also paves the way for accomplishments which are of great value in other ways, solving critical problems, maintaining military security, strengthening the economy, and improving the general health and welfare.

In the long run basic research does the same thing. It provides the knowledge and understanding of the world we live in which leads to power—power to adjust in an optimum way to our environment, to make maximum use of natural resources, and even to consider substantially altering our environment. Above all, it will uncover vast possibilities which we do not yet even know. In all this, research cannot fail to have a profound effect on our thinking, our culture and our philosophy of life. The degree to which we succeed in these endeavours does not depend primarily on money. It depends on people. For one thing it depends obviously on the number of competent scientists and engineers we have and can train. Fortunately, careful investigations seem to indicate that we can indeed train the numbers we need for the next decade, but we shall have to work at it much harder than we have been doing, and it will take a lot more money than we are now investing. A severe burden is coming on our colleges and universities, and especially our graduate schools. For this latter purpose we need to provide more funds and facilities to universities for basic research as an essential factor in advanced training. We must also direct attention to other professional training such as that of technicians and we badly need to improve the quality of instruction in education all along the line.

A country such as the United States should be able to provide, from public and private sources, the funds needed for the technological progress one wishes to make. This is a matter of priorities and continued prosperity. But the decision as to priorities lies ultimately with the people. Hence the progress we will make depends on the degree to which our citizens have a general understanding of science and technology, their potentialities and their limitations. This in turn depends on a solid background in education for our children and a live forum for information and discussion among the public generally.

Thus, in the last analysis, the degree of success we shall have in attaining our goals which involve science and technology will be directly dependent on the degree of understanding by our citizens of these objectives and their accomplishment. This is a subject which can well repay thought and effort on the part of those in the professions which are concerned.

AMERICAN SOCIETY FOR TESTING AND MATERIALS

By Dr. ROBERT F. LEGGET

Director of Building Research, National Research Council of Canada, and Vice-President of the Society

ON May 11 the American Society for Testing and Materials dedicated its impressive new headquarters building in Philadelphia with suitable ceremonies, international in character in keeping with the international scope of the Society and its work. The President of the United States sent his greetings in a personal letter that was read by Dr. A. Allan Bates of the U.S. National Bureau of Standards. Diplomatic representatives of Canada and Mexico presented appropriate greetings from their respective countries. The good wishes of the International Organization for Standardization (I.S.O.) were presented by Mr. Olle Sturén, director of the Swedish Institute of Standards, who brought with him, as a gift to the Society from his own Institute, a beautiful example of Swedish glass.

The principal address was delivered by Mr. Stewart S. Cort, president of the Bethlehem Steel Co., who illustrated the rapid growth of standards in the American economy and their increasing importance in the world-wide trade of to-day with telling examples from the steel industry. Reminding his audience how James Watt's work had been advanced by Wilkinson's improved boring machine, Mr. Cort went on to say that "the most important single development of those early industrial days was the system of the interchangeable-part manufacture—individual parts made so nearly identical that the complete device could be put together without the hard work and the high cost of shaping and fitting. A number of different inventors can claim a share of the credit for this big step forward. It was an American,

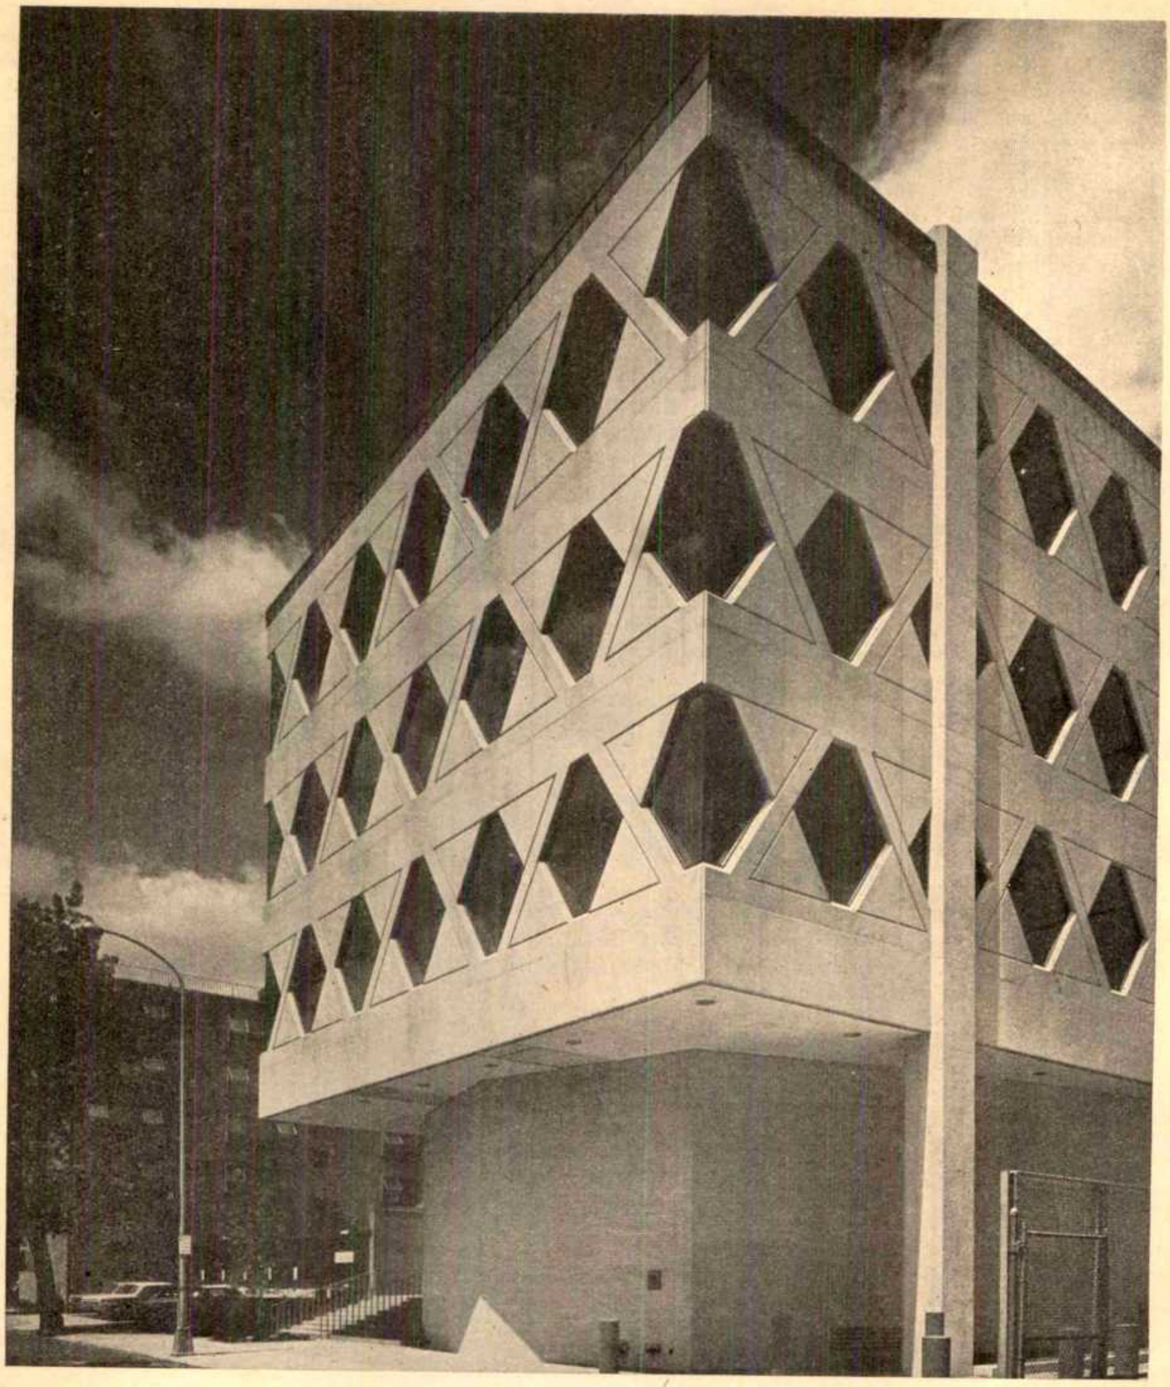

Fig. 1. New headquarters of the American Society for Testing and Materials, Philadelphia

Eli Whitney, who first developed the system on a commercial basis. . . . His secret was the jig, which he had invented to produce interchangeable parts, plus the use of power-operated tools. . . . It might seem surprising that almost one hundred years went by before the idea of standardized parts led to the idea that properties of materials from which those parts were made could also be standardized . . . the first organized meeting to discuss the subject of uniform methods of testing was held in Europe in 1882". Tribute was paid to the pioneer work of Albert L. Colby, a founding member of the American Society for Testing and Materials in 1902 and a leading chemist of the steel industry.

The new building (Fig. 1) replaces a smaller and somewhat inconvenient building on the same site, facing on Logan Square, an almost European feature of downtown Philadelphia with its impressive large fountain and park-like flower beds. The Franklin Institute and the Free Library of Philadelphia are neighbours. The architects, Carroll, Grisdale and Van Alen of Philadelphia, have achieved a masterly design in fitting so large, so convenient and so beautiful a building on so difficult a site. It is L-shaped with only a 40-ft. frontage on the square, and is 284 ft. deep and 93 ft. wide for its rear half. Sacrificing part of the 40-ft. strip has permitted the inclusion of a courtyard and garden behind the glass entrance doors (Fig. 2), giving an interesting view from the Square of the main part of the building in the rear. This is a four-storey structure which can eventually be extended to eight storeys when the need arises. On the

FOR HIGH PERFORMANCE

in routine analysis and research

Easily converted into the CF4DR Double-Beam Recording Spectrophotometer.

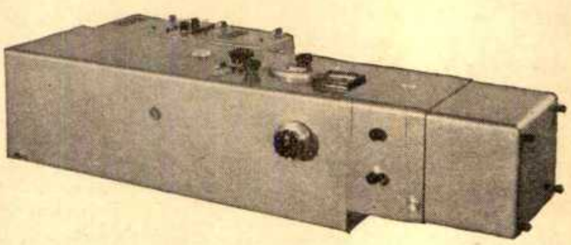
This instrument is manufactured completely at our Works, and is installed and delivered free of charge.

Full information together with details of other OPTICA spectrophotometers will be forwarded on request.

CF4 Range 185-750mμ Price £870

Range 185-1000mμ Price £950

Complete range of attachments available.



THE OPTICA CF4

AN OUTSTANDING SINGLE-BEAM HIGH-PRECISION MANUAL SPECTROPHOTOMETER.

Standard Features

- Grating Monochromator
- High Resolution
- Linear Dispersion
- Transistorised Electronics
- Mains Operated

Service Centres at London, LARkswood 2603; Manchester, CENtral 0937 and Newcastle, Low Fell 75002

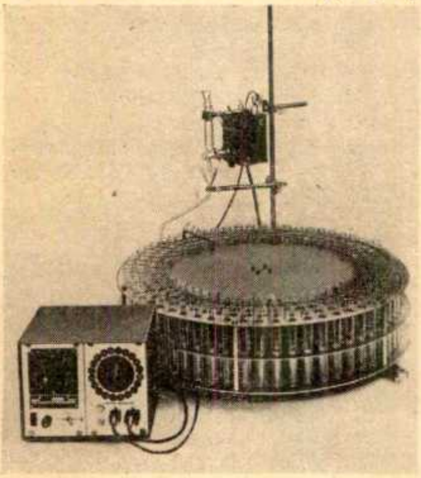
PRECISION & VERSATILITY

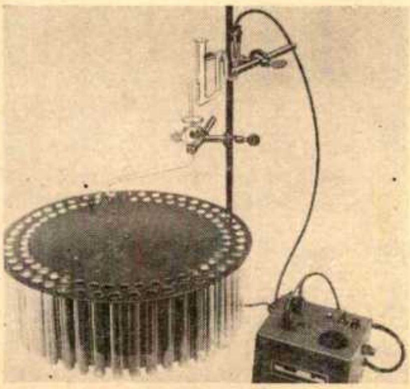
in Column Chromatography

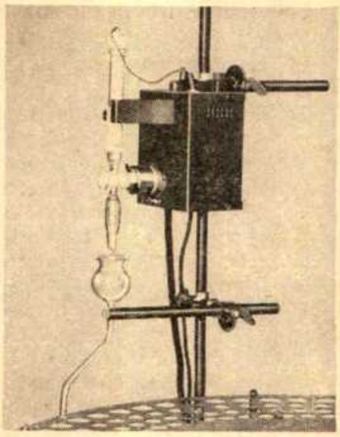


The ISCO Improved Model A (above) and Model T (right) Fraction Collectors

These two fraction collectors operate with great accuracy and reproducibility. Control is timed or volumetric, and the ISCO Volumeter gives increased precision and adjustable volume range. The Model A has a 26 in. diameter turntable holding 240 tubes. The Model T, with 9.5 in., 12.5 in., or 18 in. turntable (90 tubes each of varying capacity) can also be used with the ISCO Model D Density Gradient Fractionator.

Write or phone for ISCO illustrated leaflet.





Volumeter

The ISCO Model V Volumeter automatically measures a highly repeatable volume of effluent into each test tube, and actuates the turntable to move to the next position one second after the stopcock is closed. Models VA and VT are for use with ISCO Fraction Collectors Models A and T, respectively. Model VB is for use with any other Fraction Collector.

ground floor is a 350-seat auditorium accessible from both directions. The remaining floors accommodate all the office functions of the Society, movable partitions for all subdivisions giving a flexible floor arrangement. The Society is now elegantly and efficiently housed for many years to come.

The new facilities are already being used almost to the full, so great have been the demands on the Society during recent years. It is a unique organization, entirely voluntary in nature, self-supporting financially, and yet producing standard material specifications and test methods which are extensively used by American Government and industry, and to a somewhat lesser extent in every English-speaking country of the world. In other countries the Society's standards are frequently used as reference documents or as the basis for the preparation of a number of recommendations of I.S.O. The Society's work with I.S.O. is channelled through the American Standards Association, which also presented its greetings at the dedication ceremony through its Executive Director.

Research has always played an important part in the work of the Society and is one of the foundations on which its standards are based As a means of emphasizing its research function the Society recently made a small but significant change in its name by inserting the word 'and' between 'Testing' and 'Materials'. This was in keeping with its original charter wherein the function of the Society is stated to be "the promotion of knowledge of materials of engineering, and the standardization of specifications and methods of testing".

As further evidence of its research interests, there was established in 1960 a Division of Material Sciences, the function of which is still further to stimulate research in the field of materials. The Division has already been responsible for some outstanding symposia at annual meetings of the Society on such subjects as: "Properties of Crystalline Solids" (1960); "Major Effects of Minor Constituents on the Properties of Materials" (1961); "Stress-Strain-Temperature Relationships in Materials (1962); "Properties of Surfaces" (1963); "Irreversible Effects of High Pressure and High Temperature on the Properties of Materials" (1964); "Internal Friction, Damping and Cyclic Plasticity Phenomena in Materials" (1964). All have been published in the Society's series of *Special Technical Publications*.

The international aspect of the Society's activities is shown by the fact that of its 12,000 members no less than 1,700 come from countries other than the United States. Surprisingly these now number 73. Copies of the Society's publications are now mailed to every part of the world. A Canadian is not infrequently a member of the Board of Directors. One Canadian has already served as president. Seven Canadians hold leading offices in the technical committees through which the Society carries out its important work in the field of standardization. Mr. H. A. R. Binney, director of the British Standards Institution, was made an honorary member at the Chicago annual meeting of the Society in June and at the same meeting Dr. F. M. Lea, director of the British Building Research Station, received the Walter Voss Award.

These international links, which the Society has always enjoyed to some degree, are in keeping with its international origins, for it started in 1898 as the American branch of the International Union for the Testing of Materials. It was soon found that a separate American organization would be desirable, and so the Society was chartered, as such, in 1902. From this small start has developed the Society of to-day, with its new three-million-dollar building in Philadelphia. The headquarters of the Society have always been in the 'City of Brotherly Love', initially because the first secretary was dean of civil engineering in the University of Pennsylvania, but more recently by choice. Four men only have

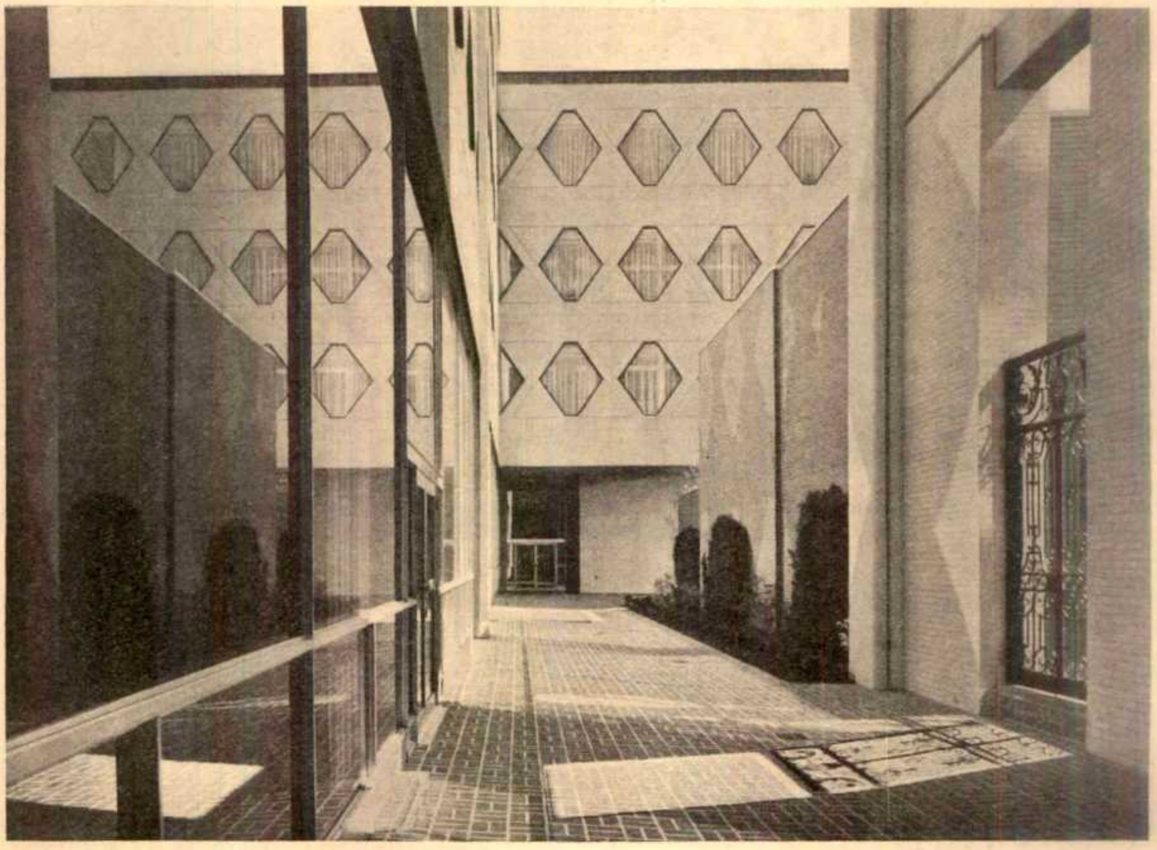

Fig. 2

served the Society as its top executive throughout its 62-year history—E. Marburg (1902–18), C. L. Warwick (1919–52), R. J. Painter (1952–60), the present incumbent being T. A. Marshall, jun.

Most scientific societies fulfil two main functions—providing a specialized service to their own members and publishing scholarly papers and books. The American Society for Testing and Materials performs these functions well but in addition it develops and publishes standards for materials and test methods that are, in effect, public documents. They now total more than 3,200. Commencing in 1964 they are being issued on an annual basis in a series of 32 volumes, having a total pagination of almost 20,000. All these documents are initially prepared and kept continually under review by 99 main technical committees aided by (one might almost say) innumerable sub-committees and working groups. Subjects range all the way from steel (Committee *A*–1) to peat (Committee *D*–29). Especially significant has been the recent establishment of Committee *F*–4 on surgical implant materials, the medical profession having solicited the aid of the Society in applying well-established engineering procedures to the standardization of the materials now used for so many and varied surgical implants.

This development is another clear indication of present-day awakening to the vital importance of standardization in fields far removed from engineering where this discipline naturally started. It confirms the timeliness and importance of the Society's new building, whence comes most of the secretarial and administrative support for all the Society's technical committees. All committee work is entirely voluntary. Some committees are now so large (one has more than 200 sub-committees) that their own separate meetings are minor scientific conferences. The focal point for committee activity is, however, the Society's annual meeting, a unique gathering. More than 3,000 men (with some women) meet throughout a whole week in order to attend working meetings of more than 1,100 technical groups. The physical arrangements for this remarkable schedule, enlivened by some general technical sessions and two invited lectures but by a minimum of social diversions, always evoke the admiration of the newcomer.

It is in the workings of the individual committees that there can be seen in a quite remarkable way the application of science to the needs of man. Here the scientist, the research worker, the university professor sit down with the engineer to pool their information in the drawing up of a standard document which can be put to public use. Compromise is essential but the very process of reaching agreement on some controversial point will often point the way to needed research. It is impossible to estimate what stimulation has thus been given to research in North America but it is certain that the influence of the American Association for Testing and Materials has been very great indeed. Although the new structure in Philadelphia, therefore, appears to be 'only an office building', it is in fact a research building and as such appears to be worthy of this brief record in the pages of *Nature*.

PLUTONIUM IN THE MARINE ENVIRONMENT

By K. C. PILLAI*, DR. R. C. SMITH and DR. T. R. FOLSOM

Scripps Institution of Oceanography, University of California, San Diego, La Jolla, California

PLUTONIUM-239 and -240 have been separated from sea water by radiochemical techniques and measured by use of an alpha spectrometer; ^{239,240}Pu has also been found to be highly concentrated in marine organisms. In addition, plutonium-238 has been detected in some of these organisms. The significance of plutonium in the marine environment and the application of concentrating organisms for trace-element detection is discussed here.

Naturally occurring plutonium has been shown to exist only in extremely small amounts, about one part in 10^{14}, in uranium-rich minerals like pitchblende and carnotite[1]. This plutonium is produced by neutron absorption of uranium-238, the neutrons necessary for this reaction arising from various sources[2]: from the spontaneous fission of uranium-238, from reactions of the type (α, n), by neutron multiplication in uranium-235 and neutrons produced by cosmic rays. On the other hand, man-made plutonium has found wide use in nuclear bombs and reactors. In nuclear explosions, plutonium isotopes can be formed by neutron capture by uranium-238 atoms or by the escape of fissile nuclides which have not undergone fission. It has been reported[3] that a total fission yield of 193 megatons was put into the atmosphere as of January 1, 1963. This amount corresponds to $2 \cdot 8 \times 10^{28}$ fissions. If we assume that fall-out particles from an explosion contain one plutonium atom per fission, this gives 11×10^{6} g or 0·68 Mc. of plutonium-239 put into the atmosphere. The analysis of air-borne debris in the first large-scale thermonuclear explosion[4] showed that the major isotope of plutonium formed was 239, with other isotopes like 240, 241, 242, and 244 being formed in much smaller quantities. Curium-242 (half-life = 162 days), the parent of plutonium-238, was also detected in minute amounts.

Plutonium isotopes are far less abundant in fall-out than strontium-90 and cæsium-137 and, relative to those of strontium-90 and cæsium-137, the half-life of plutonium-239 is very long—more than 24,000 years. Plutonium is one of the most toxic elements. It can exist in a multiplicity of oxidation states which exhibit significant differences in chemical properties, and it is thought to be relatively unrelated chemically to the essential constituents of plants and organisms. Since it is artificial, and possesses peculiar chemical properties, the presence and distribution of this element in the environment are unique and its investigation is of great interest.

Fall-out plutonium has been measured in air, soil, various human organs and in commercially available meat products[5]. However, until now, no results have been available on the levels of plutonium present in the marine environment. Concern over plutonium in the marine environment has increased since the development of SNAP (Systems for Nuclear Auxiliary Power) generators for space-vehicles. In some of these systems, plutonium-238 has been used as a source of auxiliary power[6]. It is of some importance, therefore, to acquire a general knowledge of environmental concentration-levels, distribution patterns, and the concentrating ability of marine organisms so that the consequences of a space craft failure can be asssessed[7]. Examination of the marine environment is important in this respect since the likelihood of this plutonium being deposited in the ocean's large area is high. This article summarizes preliminary findings concerning the plutonium content in sea water, and the concentration factors for this element in certain selected marine organisms.

---

* On leave from the Atomic Energy Establishment, Trombay, Bombay, on an I.A.E.A. fellowship administered by U.S. National Academy of Sciences.

The radiochemical separation of minute traces of plutonium from the whole spectrum of elements in sea water is difficult. In addition, relatively large samples are needed to provide counting statistics sufficient for accurate measurements. The preliminary concentration of plutonium from sea water (45 l.) was done by co-precipitating reduced plutonium with bismuth phosphate. This was successful when high concentrations of bismuth and phosphoric acid were used and additions of reagents were made to the sample at about 80° C in a reversed sequence[8]. In the case of marine organisms, the samples were dried and ashed in a muffle furnace at 600° C. The ash was dissolved in nitric acid, and plutonium was co-precipitated with bismuth phosphate. Plutonium was separated from the bulk of bismuth phosphate by carrying it on lanthanum fluoride. Finally, plutonium was isolated using an anion-exchange column and was then electroplated on a platinum planchet[9]. Since the radiochemical separation involved a number of steps, it was necessary to demonstrate the recovery of plutonium in each case. For this purpose, a known amount of plutonium-236 was added as a spike to all the samples before they were processed. This isotope is convenient because it is not a fall-out constituent and because its α-spectrum contains peaks in a suitable energy region. It was possible to carry out the assay without interference from other nuclides present in sea water which may have escaped chemical separation and have energies close to that of plutonium-239 (for example, 5·017-MeV α of protactinium-231, 5·305-MeV α of polonium-210) by using an α-ray spectrometer having high resolution and low background.

Since the amount of plutonium-239 measured was extremely small, it was necessary to check reagents for possible contaminants by making blank assays. Separate reagent blanks were carried out for sea water and for marine organisms because different amounts of reagents were used in each case. The blank assays were carried out in the same way as the sample; the same amount of spike was added and distilled water was used in place of the sample.

The α-counter system consists of an *ORTEC* silicon surface-barrier detector in a vacuum system, a pre-amplifier, a biased linear amplifier, and a pulse-height analyser served by a read-out system which includes a punch tape-recorder and a chart-recorder. Sensitive meters are also provided in order to monitor the behaviour of the detector. The amplifier and analyser system was set to record α-particles from 4 to 6 MeV in 200 channels. This energy range was calibrated using the 4·195-MeV α of uranium-238 and the 5·763-MeV plutonium-236. The results stored in the pulse-height analyser were read into a strip chart recorder and counting evaluations were then made from the recorded histograms.

It has been our experience that selection of a good detector is necessary in order to make reliable measurements at very low levels of radioactivity. With a selected detector having 450 mm² area, the background from the detector and amplifier system was maintained at 0·025 counts per hour per 200-keV energy-interval. The energy resolution of the detector-amplifier system was 70 keV full width at half maximum for 5·763-MeV α-particles, and the drift of this system was less than 10 keV during counting periods of 140 h.

Figs. 1 and 2 are photographic reproductions of histograms displayed by the chart recorder. Fig. 1 is an α-spectrum of 45 l. of coastal sea water and shows the small plutonium-239 peak and also the plutonium-236 standard peak (reduced to half-scale). No other α-particle peaks were detected. The resolution of the detector system is insufficient to distinguish between the α-spectra of plutonium-239 and plutonium-240. Since fall-out is expected to contain predominantly plutonium-239, and since no attempt in these measurements has been made to distinguish between plutonium-239 and plutonium-240, reference will be made to these as plutonium-239. Because the spectra of plutonium-236 and plutonium-239 contain multiple energy peaks[10], and because resolution was 70 keV (full width at half maximum), an energy interval of roughly 200 keV was considered to encompass the total number of counts (area under the peaks) in either of these α-spectra.

The activity of plutonium-239 was determined directly by comparing its peak area with the peak area of the known amount of standard plutonium-236. Using this technique, the accuracy of measurement is high since the measurement is largely independent of the chemical yield and the efficiency of the detector. The final plutonium-239 activity of the sample was calculated by subtracting the reagent blank background activity. This background, measured by counting a blank sample containing all chemical reagents and including the plutonium-236 spike, had an average value of 0·016 d.p.m. per 200-keV energy-interval. The sea-water sample with the lowest activity has more than three times this background activity. A sample of plankton obtained in 1950 prior to extensive nuclear testing was measured for plutonium-239 and this also provided background information. The background measured in this way was found to be 0·019 d.p.m. per 200-keV energy-interval. As shown in Table 2, this is zero within the accuracy of the measurement.

Table 1 summarizes the analyses of sea-water samples. The errors given are one standard deviation of the counting error. All the water analyses were made on surface samples and the work recorded here has not included the distribution of plutonium-239 in deep waters. Four samples of coastal surface water taken at the Scripps Institution of Oceanography pier at La Jolla, California,

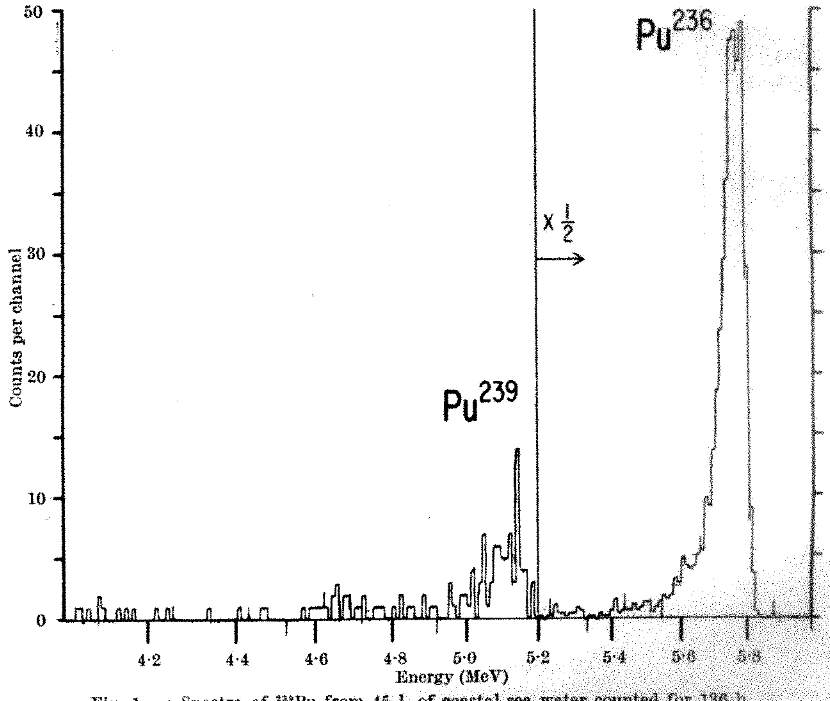

Fig. 1. α-Spectra of ^{239}Pu from 45 l. of coastal sea water counted for 136 h

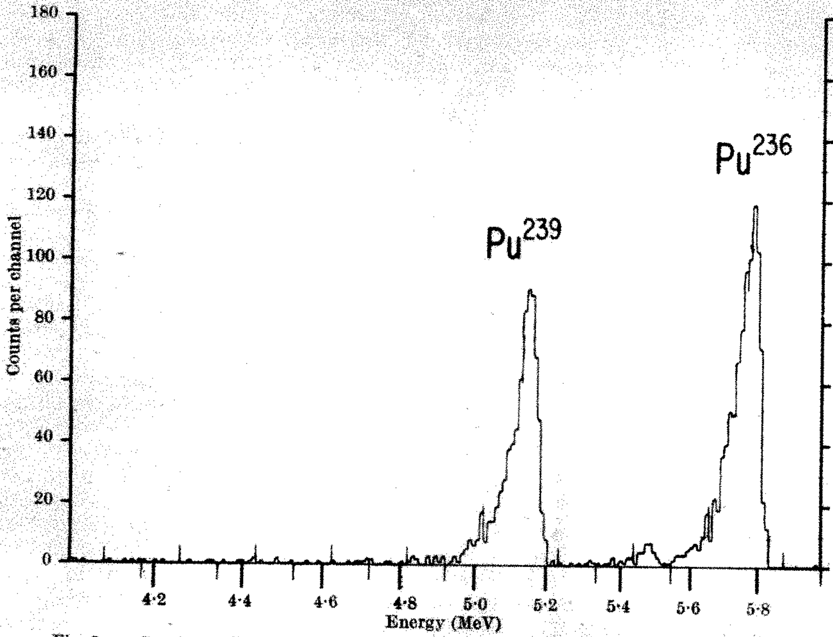

Fig. 2. α-Spectra of ^{239}Pu (and ^{236}Pu) from 760 g of palm kelp (*Eisenia arborea*) counted for 94 h

are compared with samples taken about 1,500 km and 2,500 km from the coast. It should be noted that the coastal samples are not replicates. Some variability in the concentrations in the coastal samples is to be expected when collections span several months. Large variations were observed in concentrations of cæsium-137 over similar periods during 1959–61 (ref. 11). It should be noted that the concentrations of plutonium-239 in water far off the coast are much higher than the average for the coast. These were samples at points believed to be in the gyral lying west of the major southward flow of the California Current. On the other hand, water reaching the coast at La Jolla generally comes from a flow from the south where the average precipitation and consequent fall-out are relatively low[12]. This water may also include a considerable up-welled constituent which would be expected to be low in fall-out. This pattern of relatively low fall-out in these coastal waters has also been observed for cæsium-137.

Three surface sea-water samples were taken simultaneously at one station 2,500 km from the coast. These samples were analysed for plutonium-239 (as reported in Table 1), cæsium-137 and strontium-90. The cæsium-137 content was found to be 0·46 μμc./l. and that[13] of strontium-90, 0·37 μμc./l. The plutonium-239 activity amounts to 0·7 per cent of the cæsium-137 activity, and 0·8 per cent of the strontium-90 activity in Pacific Ocean surface water as compared to 0·8 and 1·0 per cent respectively as calculated from the Richmond, California, fall-out results[14]. In spite of its very different chemical nature, plutonium apparently has not appreciably fractionated from strontium and cæsium in this oceanic surface water.

Table 1. Plutonium Activity in Surface Sea Water

*S.I.O., Scripps Institution of Oceanography.

Table 2 summarizes the results of analyses of certain representative marine organisms. These have been selected as possible indicators of environmental changes due to fall-out. The total activity of plutonium-239 in each sample is given along with the activity per kilogram of the sample's wet weight. In addition, a concentration factor, taken as the ratio of the sample activity to that of the average coastal water, is given. The average of coastal waters is used as reference in this ratio because the samples of marine organisms were taken near the southern California coast. The concentration factors are given to show that plutonium is indeed concentrated by marine organisms and to give some indication of the variability of this build-up. It should be noted, for example, that marine plants have large concentration factors whereas the negligible concentration by the fish sample indicates that discrimination against plutonium can take place at higher trophic levels. However, these concentration factors should be considered as only a relatively coarse measure of the extent to which plutonium is concentrated in marine organisms from sea water. This is because the comparison of various organisms by wet weight is somewhat arbitrary, and it is to be expected that the concentration of plutonium in organisms will depend to some extent on numerous complex variations in environmental conditions and sample collection techniques.

An intense bloom 'red tide', which occurred recently in local waters, was used to obtain a sample of phytoplankton large enough for analyses of minute amounts of fall-out activity. Surface water was pumped through a suspended standard phytoplankton net (35μ mesh) which was repeatedly back-washed with a sharp spray of sea water. The organisms caught were largely dinoflagellates, but no determination was made of what sort of organisms escaped or how much of the cell content was lost from the organisms that were caught. The zooplankton samples largely consisted of small copepods and euphausiids and were the only samples preserved in formalin. The wet weight given in Table 2 for plankton samples is the weight obtained after draining through Whatman No. 1 filters. The green algae were taken from rocks at the intertidal zone and the kelp specimens from coastal waters. For the mussel sample only the soft parts were used, and for the fish sample only the edible portion and the bones were analysed. Thus, the wet weight describes the size of the sample only roughly since it depends on the treatment given to the specimen.

Fig. 2 is an α-spectrum of 760 g of palm kelp and shows the much higher level of plutonium-239. The small peak in the region of 5·5 MeV is due to plutonium-238 and corresponds to an activity of 0·015 ± 0·005 μμc./kg. This is an example of how the concentrating property of organisms can be used to detect isotopes which could not be found in the direct analyses of sea water. The ratio of the peaks in Fig. 2, after correction for background, gives the isotopic ratio of plutonium-239 to plutonium-238 as 30 : 1 in the kelp. Assuming this same isotopic ratio for sea water, and by using the average of the coastal sea water samples for the concentration of plutonium-239, the concentration of plutonium-238 in coastal sea water is found to be 1·3 × 10^{-5} μμc./l. Traces of plutonium-238 were also evident in mussels, and quantitative measurement of this isotope should be possible in all organisms

Table 2. PLUTONIUM ACTIVITY IN MARINE ORGANISMS

Sample	Date of sampling	Wet weight (g)	Counting time (h)	Total ^{239}Pu activity (d.p.m.)	^{239}Pu ($\mu\mu$c./kg)	Concentration factor
'Red tide' (dinoflagellates)	May 1964	127	95	0·078 ± 0·010	0·276 ± 0·037	660
Green alga (*Enteromorpha* spp.)	April 1964	218	112·75	0·316 ± 0·021	0·653 ± 0·042	1,570
Giant kelp (*Macrocystis pyrifera*)	April 1964	740	47·0	0·528 ± 0·041	0·321 ± 0·025	770
Palm kelp (*Eisenia arborea*)	April 1964	760	94·0	0·759 ± 0·038	0·450 ± 0·023	1,080
Plankton (mixed coastal zooplankton)	January 1950	71	122·0	0·0036 ± 0·0047	0·023 ± 0·030	—
Plankton (mixed coastal zooplankton)	March 1964	48	88·0	0·114 ± 0·015	1·08 ± 0·14	2,590
Mussels (*Mytilus californianus*)	January 1964	1,000	122·0	0·214 ± 0·016	0·096 ± 0·007	230
Mussels (*Mytilus californianus*)	April 1964	528	98·5	0·140 ± 0·014	0·120 ± 0·012	290
Fish (bonito) (*Sarda lineolata*)	May 1964	1,185	119·5	0·0037 ± 0·0048	0·0014 ± 0·0018	3

which have high concentration factors by analysing larger quantities of these samples. Thus, while this work was principally concerned with measurement of plutonium-239 it is clear that plutonium-238 can also be detected by a suitable choice of concentrating organism.

It is of some interest to compare our results in sea water with fall-out measurements reported for land. Plutonium-239 fall-out has been measured at Richmond, California (38° N.), from 1960 until the middle of 1963[14]. Using this report, about 0·25 mc./km^2 of plutonium-239 fall-out was estimated to have accumulated at Richmond as of January 1, 1964. Assuming this amount fell in the ocean and mixed uniformly to 100 metres, a concentration of about 25×10^{-4} $\mu\mu$c./l. would be expected. This concentration is of the same order of magnitude as that indicated by our open ocean-water measurement. Further, the plutonium-239/plutonium-238 ratio of 30 : 1 found in kelp is of the same order as the average ratio reported for fall-out monitored in the United States for 1961–63.

The immediate aim of this work was to show that plutonium could be measured in the marine environment. This has been accomplished, and, in addition, a modest beginning has been made toward establishing contemporary concentration levels of plutonium-239 in marine organisms. In certain marine organisms plutonium-238 as well as plutonium-239 have been measured. Future investigation, using the techniques outlined here, could be directed to the problem of the distribution of plutonium in the oceans.

We thank Mr. G. Hamada of Hazleton Nuclear Science Corporation for his advice during the preliminary investigations, and the U.S. Coast-guard for collection of off-shore sea-water samples. This work was supported by the U.S. Atomic Energy Commission and made use of facilities supplied by the Office of Naval Research.

ANALYSES OF RADIONUCLIDES OF BIOLOGICAL INTEREST IN PACIFIC WATERS

By D. CHAKRAVARTI, G. B. LEWIS, R. F. PALUMBO and A. H. SEYMOUR
Laboratory of Radiation Biology, University of Washington, Seattle

INVESTIGATIONS of the distribution of radionuclides in marine environments have been made by the Laboratory of Radiation Biology, University of Washington, since 1946. These investigations have included radiochemical analyses of marine samples from the western and central Pacific, the north-eastern Pacific and the Arctic Ocean (Chukchi Sea). The analyses discussed here are those of samples collected recently in the Pacific Ocean. One group of samples was collected in the vicinity of Christmas Island during the 1962 tests of nuclear devices by the United States; another group was taken from near the mouth of the Columbia River where the effluent, carrying radioactive wastes from the Hanford reactors, mixes with the Pacific Ocean; and one sample was taken 250 miles off the Oregon coast.

Radionuclides from both natural and artificial sources occur in these waters. The most abundant and easily detected naturally occurring radionuclide is potassium-40. Other natural radionuclides to be expected in sea-water are radium, uranium, thorium and their decay products. Most of the artificial radionuclides generally present in the oceans are added as fall-out from nuclear detonations. The fall-out nuclides of biological interest include the fission products: strontium-89, 90, zirconium-95–niobium-95, ruthenium-103, 106, cæsium-137 and cerium-141, 144; and the induced radionuclides: manganese-54, iron-55, 59, cobalt-57, 58, 60 and zinc-65. The induced radionuclides phosphorus-32, chromium-51 and zinc-65, carried to the sea by the Columbia River, are produced by neutron activation of elements in the water used to cool the Hanford reactors.

Radionuclides in sea-water may be concentrated many thousand-fold by plankton. However, plankton constitutes only a minute fraction of the total water mass, hence the amount of radioactivity in the total water mass is greater than in the total plankton.

The concentration of radioactivity by plankton provides a convenient method for determining the presence, but not the amounts, of radionuclides in sea-water. A quantitative measurement can be made only by water analysis. The measurement of radionuclides in sea-water is difficult because of the necessity of separating and concentrating atom quantities of the nuclides from gram quantities of sea salts. β-emitting radionuclides, such as phosphorus-32 and strontium-90, require complete separation of the nuclides from the salts to reduce the absorption of β-particles by the sample. Photons from γ-emitting radionuclides, such as chromium-51, zinc-65 and zirconium-95–niobium-95, are not absorbed in the sample; but the amount of salt in a sample large enough to contain a measurable quantity of a radionuclide usually is so great that the sample geometry is reduced to an unacceptable value. Therefore, radionuclides for γ-spectrum analysis also are separated from the salt.

Our purpose here is to discuss methods used at this Laboratory for the analyses of radionuclides in sea-water and to present the results of these analyses. The methods and results of analyses of Christmas Island samples have been reported by Welander and Palumbo[1], and those of the Columbia River samples are reported by Seymour and Lewis[2]; however, they are reviewed here to present a summary of the Laboratory's methods and results. In addition, values for strontium-90, as determined by other investigators, have been included to indicate the world-wide distribution of this radionuclide in the surface waters of the oceans.

Collection and preparation procedures. Surface sea-water samples were collected from three areas in the Pacific Ocean: in the vicinity of Christmas Island (approximately 2° S.–2° N. latitude and 153° W.–168° W. longitude); within 20 miles of the Columbia River (approximately 46° N. and 124° W.); and 250 miles off the Oregon Coast (approximately 45° N. and 130° W.).

The Christmas Island samples were collected during the summer of 1962 and the samples taken near the Columbia River were collected during January 1961–June 1962. 10 l. of sea-water were filtered using 47-mm *HA*-type 'Millipore' filters with 0·45μ pore size. After filtering and chemical separation, the samples were analysed for γ-emitting radionuclides. The Christmas Island samples were analysed also for strontium-90.

On March 20, 1963, a 100-l. sample was collected off the Oregon coast. This sample was divided into 50-l. aliquots which were analysed by different methods for strontium-90. The particulate matter was separated from the water by centrifugation, rather than by filtration, using an *SS*-4 Servall enclosed superspeed centrifuge with the Szent-Györgyi continuous-flow system. At 17,000 r.p.m., the flow-rate was 200 ml./min. This system was about 30 per cent as effective as the 'Millipore' filter in removing the particulate matter.

Chemical separation. A hydroxide precipitation method was used for the samples taken from near the Columbia River mouth, and a sulphide precipitation method adapted from Sood, Golden and Velten[3] was used for the Christmas Island samples. The sulphide method was preferred because it proved to be simpler and equally reliable.

Hydroxide precipitation method. Carriers of manganese, cobalt, iron, zinc and chromium (200 mg each) in their chloride form were added to 10 l. of filtered sea-water sample. Under constant stirring, a predetermined amount of concentrated ammonium hydroxide was added drop-wise and the precipitate was allowed to settle for 15 min. Then a few more drops of ammonium hydroxide were added to check the completeness of the precipitation. The amount of concentrated ammonium hydroxide required for complete precipitation of a 10-l. sample varied with the salinity according to the equation:

$$V = 100 + 3{\cdot}7S$$

where V is the volume of reagent in ml. and S is the salinity of the sample in parts per thousand. This relationship is based on observations in the range of 10–32 per cent. The precipitate was allowed to settle overnight or longer, after which time most of the clear supernate liquid was siphoned off. The remaining mixture was filtered through a Whatman-42 filter paper under vacuum. The precipitate was wet-ashed with concentrated nitric acid and 30 per cent hydrogen peroxide, dried in a 250-ml. 'Pyrex' beaker and counted. The elements present in greatest quantity in sea-water remain in the supernate. This fraction also was dried and counted. The chemical yields by the hydroxide precipitation method for manganese-54, cobalt-60, iron-59, zinc-65 and chromium-51 ranged from 89 to 100 per cent.

Sulphide precipitation method. Carriers of lanthanum, iron, cobalt, zinc, nickel, zirconium, ruthenium, cerium, cæsium and strontium were added to 'Millipore'-filtered sea-water samples, with cæsium and strontium serving as hold-back carriers. The sample was acidified to dissolve any suspended matter, heated to 80° C and the *p*H then adjusted to 11 with ammonium hydroxide. Hydrogen sulphide was bubbled slowly into the solution under constant stirring. After the solution had been saturated with hydrogen sulphide, it was taken off the heat and allowed to settle overnight. After separation from the supernate by filtering, the precipitate, containing ruthenium, cerium, cobalt, chromium, zinc, iron, zirconium and lanthanum, was placed in an eight-ounce plastic jar and counted. The percentage chemical yields by the sulphide precipitation method for zinc-65, cobalt-60, zirconium-95–niobium-95, cerium-144 and ruthenium-103 tags were in agreement with those of Sood *et al.*[3] and ranged from 90 to 97 per cent. Strontium was retained in the supernate, as evidenced by less than 1 per cent strontium-85 activity in the precipitate. As in the hydroxide method, potassium and cæsium remained in the supernate with the bulk of the sea salts and no further chemical separation was made.

Strontium-90. The supernate from the foregoing procedure was acidified, hydrogen sulphide was driven off by heat and the *p*H was adjusted to 5 with ammonium hydroxide and acetic acid. Strontium was co-precipitated with calcium as the oxalate using ammonium oxalate. The precipitate, after filtering, was wet-ashed with nitric acid and hydrogen peroxide. The ash residue was re-precipitated in 80 per cent nitric acid to reduce the calcium–strontium ratio. The strontium nitrate thus obtained was dissolved in 0·2 N hydrochloric acid and the resulting solution was passed on to a 'Dowex 50*W X*-8' (100–200 mesh) ion-exchange resin column. After rinsing with 0·2 N hydrochloric acid to remove any unadsorbed contaminants, 0·5 per cent oxalic acid was added to remove radioiron. The column was stripped off yttrium-90 as yttrium citrate complex with 5 per cent ammonium citrate at *p*H 3·5. Storage time for 2 weeks was allowed for the secular equilibrium between strontium-90 and yttrium-90 to be established. The column then was re-eluted with a minimum volume of ammonium citrate, the eluate acidified to break up the yttrium citrate complex and the resulting solution was passed on to a short-stemmed eyedropper column containing a 2-cm resin bed of 'Dowex 50*W X*-8' (100–200 mesh). When the yttrium-90 was adsorbed to the resin bed the citrate mass was removed with dilute acid (0·2 N nitric acid) wash. The yttrium-90 was stripped off the column with about 5 ml. of 6 N nitric acid on to a stainless steel planchet, dried and the relatively mass-free residue counted. This strontium-90 method was adapted from a procedure developed by Kawabata and Held[4].

Strontium-90 was determined in the sea-water from off the Oregon coast by this method and also by the method of Miyake, Saruhashi and Katsuragi[5]. In the latter method an oxalate precipitation of calcium and strontium is used, followed by EDTA-masking of calcium and recovery of yttrium-90 as yttrium hydroxide after secular equilibrium is reached.

Phosphorus-32. The method of extracting phosphorus-32 from sea-water was suggested by the work of Proctor and Hood[6] and Murphy and Riley[7]. Sea-water was placed in a separatory funnel and allowed to react with a composite reagent containing ammonium molybdate, sulphuric acid, ascorbic acid and potassium antimony tartrate[7]. Seven parts of *N*-butanol were added to 150 parts of sample, and the solution was made more acidic to favour extraction of the molybdenum blue. After extraction the organic layer was backwashed with dilute sulphuric acid and dried under low heat. The residue was dissolved in a minimum amount of aqua regia and again evaporated to dryness. The residue was dissolved in 50 ml. of 15 per cent hydrogen peroxide and made up to 2 N in hydrochloric acid. This mixture was added to a separatory funnel and the molybdate extracted with an equal volume of tri-butyl phosphate. The organic layer was discarded and the aqueous layer extracted again with an equal volume of tri-butyl phosphate. The aqueous layer was then dried on a steel planchet and counted for phosphorus-32. (A more complete description of the method will be reported by Chakravarti, Tuell and Larson[8].)

Counting systems. The γ-counting system included a 3-in. solid crystal of sodium iodide, thallium activated, used in conjunction with a 512-Nuclear Data 120 analyser with an *X–Y* recorder and a digital print-out. Calculations were carried out on an IBM 709 digital computer programmed to analyse for nine isotopes and to express results in picocuries (μμc.) per g or per l. at time of collection. Only values which were greater than the background plus the 95 per cent counting error were considered significant; all other values were considered to be zero.

Two types of low-background Geiger-Müller counters were used, one for yttrium-90, another for phosphorus-32. The systems included sufficient massive shielding and cosmic-ray guard tubes to reduce the background to approximately 1·5 and 1·0 counts per min, respectively. The counting efficiencies were approximately 25 per cent for yttrium-90 and 40 per cent for phosphorus-32. All counts were standardized and the results are expressed in picocuries per litre (pc./l.) at the time of collection.

Table 1. RADIONUCLIDES IN FILTERED SURFACE SEA-WATER FROM TWO AREAS OF THE PACIFIC OCEAN (VALUES IN pc./l.)

Radio-nuclide	Mouth of Columbia River *N′/n*†	Average	Maximum	Christmas Island* *N′/n*†	Average	Maximum
	January–September 1961					
^{51}Cr	10/25	150	770			
^{65}Zn	15/25	21	350			
	November 1961–June 1962			May–July 1962		
^{51}Cr	7/9	580	1,300			
^{65}Zn	8/9	5·1	12	4/24	1·3	13
^{95}Zr–^{95}Nb	7/9	4·5	16	11/24	16	71
^{103}Ru	5/9	0·79	2·5	4/24	3·7	32
^{141,144}Ce	9/9	9·4	27	13/24	10	46
^{137}Cs				3/24	0·62	11
^{60}Co				2/24	0·38	7·0

* From ref. 1.

† *N′/n*, Number of samples with radioactivity greater than background plus the 95 per cent counting error/No. of samples analysed.

The average and maximum values of radionuclides, except those of strontium-90, potassium-40 and phosphorus-32, in sea-water samples are given in Table 1. This Table is a summary of the results of analyses of samples collected at various times during the period indicated. The appearance of mixed fission products after September 1961 in the samples from the mouth of the Columbia River is the result of fall-out, presumably from the nuclear tests by the U.S.S.R. in October 1961.

Chromium-51, produced in the Hanford reactors, was the most abundant radionuclide in the coastal waters near the mouth of the Columbia River, where it is of interest to the oceanographer as a tag of Columbia River water and sediments. Chromium-51 was neither expected nor detected by visual inspection of the γ-spectra of the Christmas Island water samples.

The two values for strontium-90 from the single sample of sea-water from off the Oregon coast analysed by both the method of Miyake, Saruhashi and Katsuragi[9] and the modified Kawabata–Held method[4] described here were 0·037 ± 0·003 (95 per cent counting error) and 0·041 ± 0·009 pc./l., respectively. The latter was the faster of the two methods and produced a sample of lesser mass. The reduction of mass was from several grams to a few milligrams. The values for strontium-90 in surface sea-water from off the Oregon coast and from other areas round the world ranged from 0·01 to 3·1 pc./l. and are presented in Table 2. This radionuclide seems to be ubiquitous in surface waters since no zero values are given in these reports.

Table 2. STRONTIUM-90 IN SURFACE SEA-WATER (VALUES IN pc./l.)

Ref.	Location and dates	No. of samples analysed	Range of values
—	250 miles off Oregon coast, January 1962	1	0·04
1	Christmas Island, January 1962	5	0·03–0·2
10	Atlantic Ocean and Carribbean Sea, 1956–60	60	0·031–0·30
11	Chukchi Sea, 1959–62	7	0·005–0·27
12	Pacific and Indian Oceans, 1960–61		
	0°–40° N	25	0·1–0·9
	0°–40° S	6	0·06–0·1
	60° S (Antarctic)	2	0·01–0·02
9	Western North Pacific Ocean, 1958–60	15	0·6–3·1

Table 3. PHOSPHORUS-32 IN FILTERED SURFACE SEA-WATER FROM NEAR THE MOUTH OF THE COLUMBIA RIVER, JULY 1963 (VALUES IN pc./l. ± S.D.)

Station	Miles from mouth	Salinity (parts per thousand)	No. of determinations	^{32}P
63	30	31·76	3	3·57 ± 0·60
69	24	31·63	1	5·15
74	18	27·80	3	8·03 ± 0·58
75	9	27·74	3	4·68 ± 1·63

Values for phosphorus-32 in the sea-water near the Columbia River mouth are given in Table 3. These values ranged from 3·6 to 8·0 pc./l. To our knowledge no other values for phosphorus-32 in sea-water have been reported.

In order to compare the radioactivity from naturally occurring and artificial radionuclides in sea-water, the values for potassium-40 were determined as well as the radionuclides discussed here. For samples collected near the mouth of the Columbia River, these values ranged from 190 to 370 pc./l. and were related to the salinity values. The calculated value for potassium-40 in sea-water of 35 parts per thousand salinity is 330 pc./l.

This work was carried out under contract *AT* (45–1) 1385 with the U.S. Atomic Energy Commission.

REORGANIZATION OF CIVIL SCIENCE IN BRITAIN

In the House of Commons on July 28, Sir Harry Legge-Bourne asked the Secretary of State for Education and Science if he would make a further statement on the measures to be taken in consequence of the Trend Report on the organization of civil science. Mr. Quintin Hogg replied that, as foreshadowed in the statement issued by the Prime Minister on February 6, it was proposed to implement the recommendations of the Report with some modification. These changes would necessitate legislation which was now being prepared for introduction at an early opportunity. This legislation would include provision for the increased responsibilities of the Secretary of State.

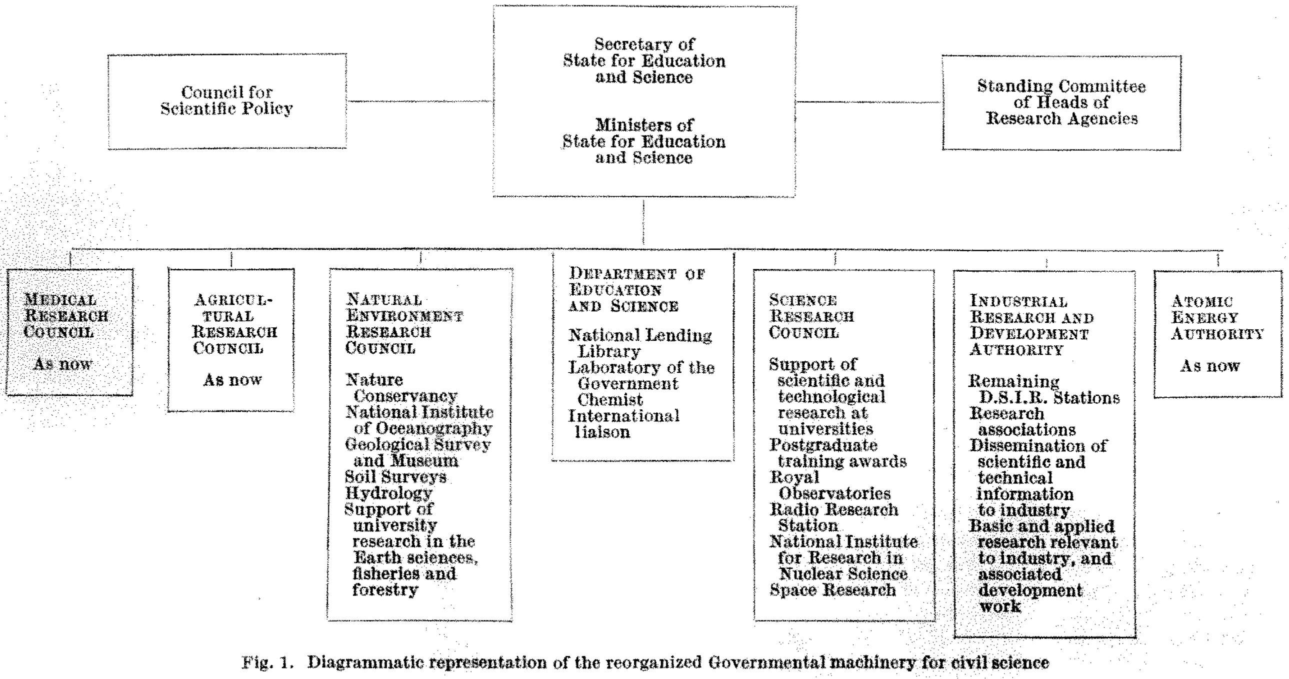
The present Advisory Council for Scientific Policy will be replaced by a body on the lines recommended by the Committee, to be called the Council for Scientific Policy. The Council will advise the Secretary of State in the formulation and execution of general scientific policy. Specifically, the Council will advise the Minister on national scientific needs as a whole, including the fostering of new growing points; on the broad allocation of resources; on scientific man-power; on international scientific policy; and on the administrative machinery for the promotion of scientific research. As recommended by the Committee, the Council will consist entirely of independent members. Assessors appointed by interested bodies, including the Board of Trade, the Ministry of Aviation, the Atomic Energy Authority, the University Grants Committee and the Research Councils, will see the papers and attend by invitation. The Council will have its own staff and secretariat which will form part of the Department of Education and Science.

It also is proposed to form three new bodies as follows:

(1) *The Science Research Council.* The Council will take over from the Department of Scientific and Industrial Research the function of supporting scientific and technological research at universities through ear-marked grants in fields other than those for which other Research Councils are responsible. It will also take over the Department's function of making training awards to postgraduate students in science and technology, other than those who are supported by the more specialized Research Councils. The Science Research Council will take over responsibility for the National Institute for Research in Nuclear Science and the Royal Observatories at Herstmonceux and Edinburgh. It will also assume responsibility for the scientific space programme and, in particular, the work of the Space Research Management Unit of the Department of Education and Science and the Department of Scientific and Industrial Research Radio Research Station. The Ministry of Aviation and the University Grants Committee will be represented on the Council by assessors.

(2) *The Natural Environment Research Council.* This Council is to be formed, following the recommendation of the Committee on the Organization of Research into Natural Resources and the Committee on the Organization of Civil Science, to support research in the field of environmental sciences and natural resources. Specifically, the Council will support research in geophysics, geology, oceanography, fisheries, hydrology, forestry, terrestrial ecology and nature conservation. It will provide research grants to universities and make training awards to postgraduate students in these fields. The Council will assume responsibility for: (*a*) the Geological Survey and Museum; (*b*) the Soil Surveys; (*c*) the Nature Conservancy; (*d*) the Hydrology Research Unit and the Committee on Hydrological Research.

The Council will finance and co-ordinate the work of these organizations. It will take over from the Navy Department and the Development Commission responsibility for supporting the National Institute of Oceanography. The Council will establish a Fisheries Advisory Committee on the same lines as the present Advisory Committee on Fishery Research of the Development Commission. On hydrology, the Council will maintain close contact with the Water Resources Board, which also has research functions. It will support research in geomagnetism and seismology undertaken by the Meteorological Office and will be associated with its general programme of research. Under these arrangements, the Council will be in a position to foster and co-ordinate



Council for Scientific Policy
Secretary of State for Education and Science
Ministers of State for Education and Science
Standing Committee of Heads of Research Agencies
Medical Research Council
As now
Agricultural Research Council
As now
Natural Environment Research Council
Nature Conservancy
National Institute of Oceanography
Geological Survey and Museum
Soil Surveys
Hydrology
Support of university research in the Earth sciences, fisheries and forestry
Department of Education and Science
National Lending Library
Laboratory of the Government Chemist
International liaison
Science Research Council
Support of scientific and technological research at universities
Postgraduate training awards
Royal Observatories
Radio Research Station
National Institute for Research in Nuclear Science
Space Research
Industrial Research and Development Authority
Remaining D.S.I.R. Stations
Research associations
Dissemination of scientific and technical information to industry
Basic and applied research relevant to industry, and associated development work
Atomic Energy Authority
As now

Fig. 1. Diagrammatic representation of the reorganized Governmental machinery for civil science

investigations associated with the planetary environment of the Earth, air and water.

(3) *The Industrial Research and Development Authority.* This body will be formed to continue and extend the work hitherto carried on by the Department of Scientific and Industrial Research in relation to industrial research and development. It will carry out research in its own establishments; support co-operative industrial research associations; encourage and support advanced development work arising out of these activities and disseminate scientific and technical information to industry. In development contract work, it will act in consultation with the National Research Development Corporation and use it as its agent when this is appropriate. It will not be concerned solely with applied research and development. It will be an important part of its functions to support basic research which may have important implications for industry. The Authority will consist of a full-time chairman and part-time members from industry, science and technology. It will also include representatives from the National Research Development Corporation, the Board of Trade, the Ministry of Aviation and the National Economic Development Council.

The Authority will take over the responsibility for all stations hitherto belonging to the Department of Scientific and Industrial Research except the Radio Research Station, the Geological Survey and Museum, and the Hydrology Research Unit, and, as mentioned later, the Laboratory of the Government Chemist. The future position of the National Physical Laboratory is still under consideration. It is, however, intended that a close link with the Royal Society of London will be maintained.

There will be no change in the present functions of the Medical Research Council and the Agricultural Research Council.

The Department of Education and Science will assume responsibility for the National Lending Library for Science and Technology and for the Laboratory of the Government Chemist.

Important questions arise about the position of staff which will be transferred, under these proposals, to the Industrial Research and Development Authority and to the new Research Councils from the Department of Scientific and Industrial Research and other organizations. These questions are under consideration. There will be full consultation with the appropriate staff organizations before decisions are taken on these matters.

As recommended by the Committee on the Organization of Civil Science, the Overseas Research Council will be dissolved. Its functions have now passed in the main to the Department of Technical Co-operation and its advisory bodies.

Under these measures of reorganization, all the functions of the Department of Scientific and Industrial Research will pass to the new research agencies referred to here, and to a minor extent, to the Department of Education and Science. They will thus bring to an end the Department of Scientific and Industrial Research in its present form, and create a wider group of research organizations, operating under the general supervision of the responsible Minister, acting with appropriate advice. It will be necessary for the research agencies to work closely together in certain fields of scientific work and marginal adjustments in their functions may be necessary from time to time. It is the Government's intention that these arrangements should be kept under review, with the advice of the Council for Scientific Policy, in order to meet the needs of developments in science and technology. The Government considers that these measures of reorganization, which are being undertaken after a full study of the whole field by the Trend Committee, will provide both a substantial measure of autonomy for the Research Councils, and also the means of developing a coherent national scientific policy. In particular, it believes that these measures will enable the distinguished work of the Department of Scientific and Industrial Research during the past fifty years to be developed and extended on an expanding scale, and with increasingly rewarding results.

NEWS and VIEWS

Director of the Microbiological Research Establishment, Porton: Dr. D. W. W. Henderson, C.B., F.R.S.

Dr. D. W. W. Henderson was appointed director of the Microbiological Research Establishment at Porton in 1946, at which time the Establishment was housed in cramped huts associated with the Chemical Defence Establishment. Plans for a new building were, however, under discussion. The first few years of Dr. Henderson's directorship were largely devoted to completing these plans and seeing the building built and equipped—a period of hard work and struggles with authority in which the new director received great help and support from the late Lord Hankey. The magnificent laboratories that now house the Microbiological Research Establishment are a standing tribute to the foresight and acumen of Dr. Henderson, Lord Hankey and the band of distinguished microbiologists who stood behind the enterprise. Dr. Henderson had worked at Porton during the Second World War as a seconded member of the scientific staff of the Lister Institute, which he had joined in 1935. The Lister Institute has always been a leading centre of microbiological research; the work of Sir Paul Fildes and of Dr. Muriel Robertson, from the days of the First World War onwards, was pre-eminent: it was fitting that the director of the Microbiological Research Establishment should be chosen from the Lister Institute.

Before 1935, Dr. Henderson had been a lecturer in bacteriology in the University of Durham (1926–31) and had held Carnegie (1931–32) and Beit Memorial (1932–35) research fellowships. In 1946 he was awarded the Medal of Freedom, Bronze Palm, of the United States. He was made a Commander of the Bath in 1957, and elected Fellow of the Royal Society in 1959. He became president of the Society for General Microbiology in 1963. In spite of the many and exacting tasks that fall to the director of such an establishment as the Microbiological Research Establishment, Dr. Henderson has maintained a steady programme of his own research, ranging over various immunological and bacteriological topics. He has been a most successful stimulator of the younger people of his staff. Under his direction, the Establishment has developed into one of the leading centres of microbiological research in the world. Dr. Henderson retired from the directorship on August 1. However, he will continue to undertake research at the Establishment.

Dr. C. E. G. Smith

Dr. C. E. G. Smith has been appointed director of the Microbiological Research Establishment, at Porton, Wiltshire, in succession to Dr. D. W. W. Henderson, as from August 1. Dr. Smith is an honours graduate of the University of St. Andrews. After holding appointments in the Cumberland Infirmary, Carlisle, from 1947 until 1948, he joined H.M. Colonial Medical Service in 1948. He then held various appointments in Malaya, and while at the Institute of Medical Research at Kuala Lumpur did research on virus diseases. In 1957 Dr. Smith was appointed senior lecturer in bacteriology at the London School of Hygiene and Tropical Medicine. In 1960 he became a member of the World Health Organization's study group on arthropod-borne viruses. Since 1961 Dr. Smith has been reader in virology in the University of London at the London School of Hygiene and Tropical Medicine. He is also head of the Arthropod-borne Virus Research Unit financed by the Department of Technical Co-operation.

Human Environment in the Institute of Archæology: Prof. G. W. Dimbleby

DR. G. W. DIMBLEBY, who has recently been appointed to the chair of human environment in the Institute of Archæology, London, took an honours degree in botany at Oxford in 1939. He later worked on soil problems—particularly on oxidation-reduction potentials as measures of soil activity. During the Second World War, he was in the Royal Air Force and applied his powers of observation and his ecological training to the interpretation of air photographs and was largely instrumental in developing methods for the detection of decoy sites in enemy-occupied territory designed to lead Allied bombers astray. After the War, Dr. Dimbleby was appointed as ecologist in the Forestry Department of the University of Oxford. His early work on heathlands was concerned with the natural succession back to deciduous woodland if the heaths were protected from fire. He found that this was accompanied by progressive regeneration of the soil which implied that the poor state of the soil under heathland did not reflect its full potential. To find out what this might have been, Dr. Dimbleby set out to investigate soils buried beneath earthworks of different ages, using pollen analysis and comparative soil typology as his main tools. It became apparent that the process of deterioration had its origin in the initial forest clearance by Bronze-Age (or even earlier) man, and that it was not determined purely by climate or parent material. The original forest was a mixed deciduous one on a brown forest soil, but traces of podzolization appeared during the farming phase which followed clearance and the process of degradation has continued ever since. On the face of it, it may seem a far cry from forestry to archæology, but Dr. Dimbleby's botanical and pedological investigations have revealed such a close connexion between the activities of early man and the state of the land to-day (and therefore its use) that his work has been fundamental to both disciplines.

Deputy Director of Mullard Research Laboratories: Dr. K. Hoselitz

DR. K. HOSELITZ has been appointed deputy director of Mullard Research Laboratories. He will continue as head of the Laboratories' Solid State Physics Division. Dr. Hoselitz was educated at the Universities of Vienna and Bristol. He gained his Ph.D. at Bristol in 1942 and afterwards joined the Permanent Magnet Association as a research scientist. He was promoted director of the Association's Central Research Laboratories in 1947. In 1952 he joined Mullard Research Laboratories to establish the Solid State Physics Division. The Division has since grown to a strength of more than 100 and has made notable contributions in the fields of semiconductors, magnetic materials and low-temperature physics. Dr. Hoselitz, whose special subjects are magnetism and the properties of metals and alloys, is the author of a textbook on those subjects and has contributed to several other books. Mullard Research Laboratories are near Redhill, Surrey, and employ about 700 people, of whom more than 200 are graduate scientists.

Post Office Research Station

IT has been announced that the Post Office Research Station at Dollis Hill is to be moved to the vicinity of Martlesham, in Suffolk. The aim is to start the move about 1968. The Research Station, which employs some 1,400 staff, has occupied its present site at Dollis Hill, London, since 1912. It has been recognized for some time that the Station would have to be moved because the present site is severely congested and there is not enough space to allow for development. The area chosen is less than 2-h travelling time from London, and is near the University of Essex.

Agricultural Research Council Unit of Nitrogen Fixation

THE Agricultural Research Council has announced, in consultation with the authorities of Queen Mary College, University of London, that its Unit of Nitrogen Fixation will be leaving the College owing to difficulty of accommodation there. It is being transferred to the University of Sussex, where new laboratories will be erected to accommodate it. The Unit will continue to be directed by Prof. J. Chatt, who is resigning the chair of inorganic chemistry at Queen Mary College. The Unit was established to investigate the mechanism of nitrogen fixation. Dr. J. R. Postgate, formerly of the Microbiological Research Station, Porton, is in charge of the biological aspects of the research.

Steroid Reference Collection

A Steroid Reference Collection, established by the Medical Research Council, on the advice of their Clinical Endocrinology Committee and with the aid of generous gifts of steroids from the pharmaceutical industry, can supply to laboratories working on steroid metabolism, small quantities (about 2 mg) of reference steroids. These steroids, which are mainly hormone metabolites, are intended as standards for such procedures as paper chromatography, colour reactions, infra-red measurements and mixed melting-point determinations; larger quantities (5–20 mg) can, on occasion, be supplied for studies of new analytical procedures. Applications for samples, with a brief statement of the purpose for which they are required, should be sent to Prof. W. Klyne, Chemistry Department, Westfield College, London, N.W.3, from whom a list of available compounds can also be obtained.

Water Pollution Research

ANYONE revolted by sewage solids on beaches will welcome the investigations described in the recent report of the Department of Scientific and Industrial Research Water Pollution Research Board (*Water Pollution Research, 1963*. Pp. vi + 142 + 4 plates. London: H.M.S.O., 1964. 8*s*. 6*d*. net). The results indicate that maceration and screening can prevent visual offence without increasing the concentration of coliform bacteria in the sea. It should be possible to site discharges so that the concentrations of coliform bacteria (and hence pathogens) encountered by bathers signify a negligible risk of infection. Better treatment of industrial and domestic wastes is an important part of the work of the Laboratory, leading to cleaner rivers. In particular, the analysis made of the conditions favouring the oxidation of ammonia to nitrate in the activated sludge process should enable more works to attain consistent nitrification. Work on rivers continues to concentrate on the toxicity of various effluent materials and the oxygen balance. Investigations of individual toxins enable predictions to be made of the toxicities of mixtures of toxins. These agree well with experimental observations and can be used to show the dilution needed for an effluent, or if the removal of one toxic factor would allow fish to inhabit the river. It is important for all aquatic biologists to note that a significant source of error in the standard Winkler procedures for oxygen has been found, which means that the oxygen solubility values in a number of recent publications are incorrect.

Zoology in South-west Africa

Cimbebasia, issued by the State Museum, Windhoek, South-west Africa, records present zoological research in that country. No. 8, December 1963, is an interesting account by R. F. Lawrence of the Solifugae of South-west Africa, a country that seems to offer a particularly favourable ecology to these creatures, for no less than 10 per cent of the 800 known species are found there. Although the paper is primarily systematic, the preliminary sections on the biology of these peculiar arachnids is of special value. *Cimbebasia* (No. 6; November 1963) contains four papers on various reptiles and one each on mites and diatoms, mostly by members of the Museum's staff.

Boliland Region of Sierra Leone

A 'BOLI' is the term for a flat treeless grassland that is flooded during the rainy season, and a survey of the bolilands was called for in order to delineate areas suitable for rice cultivation. The work was carried out under the Colonial Development and Welfare Scheme, and the results are described by A. R. Stobbs in *The Soils and Geography of the Boliland Region of Sierra Leone* (Pp. 45 + 12 plates. Freetown, Sierra Leone: Government Bookshop, London; Crown Agents for Overseas Governments and Administrations, 1963. 28*s*.). The area concerned consists of a strip about 140 miles long and 25 miles wide, with an annual rainfall of up to 130 in., mainly in a six-month period. The soils of the undulating upland are derived from sandstones and sandy shales; mudstones and shales, weathering into puddled clay subsoils, underlie most of the bolis, which are poor in mineral nutrients and have not attracted settlement as have the more fertile adjacent soils. The mapping of the soils was based on a geomorphological interpretation of aerial photographs, extended by the identification of soil series, which is a method of great value in a large area with poor communications but with uniform climate and geological pattern; six individual typical riverain and individual bolis were also mapped on a large scale to show the effects of variations in height on the flooding régime and to provide a basis for experimental work. The soils are classified, on the system that has already proved of value in West Africa, into the soil groups: oxysols, groundwater laterites, acid gleisols and alluviosols. Typical profiles are described and analytical results are appended, and comparisons are made for planning future development. There is a preliminary description of the existing plant communities by T. S. Bakshi. The land use in the uplands is based on shifting cultivation with bush fallow; there is a wide range of crops, but it is just subsistence farming and there is room for considerable improvement. In the flood plains, water control would enhance the possibility of swamp rice and dry-season pasture.

Witchcraft and Sorcery in Oceania

IN his presidential address to the Anthropology Section of the Australian and New Zealand Association for the Advancement of Science, Prof. M. G. Marwick, of Monash University, examined some aspects of the sociology of witchcraft and sorcery (*Australian Journal of Science*, **26**, No. 9; 1964). In Oceania, one of the well-founded propositions of the sociology of sorcery and witchcraft does not seem to apply. Elsewhere, especially in Africa, it has been repeatedly recorded that both believed attacks and accusations of witchcraft and sorcery occur only between persons already linked by close social bonds, but in Oceania it is more often reported that the sorcerer, who seems to be commoner than the witch, is believed to direct his destructive magic outside his own group. A corollary to the generalization supported by the African material is that the relationship between alleged witch and sorcerer and believed victim is not only close but also strained; and this fact gives a means of detecting the tension-points of a social structure by the frequency with which attacks of witchcraft and sorcery are believed to occur between persons standing in various relationships. Prof. Marwick suggests that the person who carries out field-work on the sociology of Oceanian sorcery or witchcraft might bear the following points in mind. First, terms such as sorcery and witchcraft must be clearly defined and the differentiation between destructive magic socially approved and that socially condemned should be maintained; for the difference between them is, for clear reasons, material to sociological analysis. Secondly, the well-established principle of comparing the ideal with the real applies in this field of enquiry as much as in any other. Thirdly, beliefs in sorcery and witchcraft invariably have a social setting in a sense that they mediate, though they sometimes complicate, the living together of people in the on-going process we call a society. These considerations mean that, fourthly, the field-worker, in collecting his material, has to direct particular attention to the three central characters, the accuser, the alleged sorcerer or witch and the believed victim, and to the social relationships, the rivalries and the alliances between them. Finally, the ethnographer should again apply a well-established canon of field-work to his particular topic, that is, when he cannot observe the relationships believed to be involved in a particular instance of misfortune, and even when he can, he should not rely on only one informant for each case, but should record the interpretations of different persons differently placed in relation to the central characters.

Spiral Structure in the Andromeda Nebula

THE Great Nebula in Andromeda has played an important part in the development of our knowledge of galaxies. The late Dr. Walter Baade initiated many investigations of the Nebula which are now being completed by his colleagues. The results of an examination of the emission nebulæ in the Nebula have just been published (Baade, W., and Arp, H., *Astrophys. J.*, 139, 1027; 1964). At one time it had been thought that no gaseous emission nebulæ were present in the Andromeda Nebula. Baade doubted this, and accordingly photographed the Nebula with the 100-in. telescope at Mount Wilson, using various specially selected combinations of photographic plates and filters. Photographs taken in different wave-length regions were compared, and in all 688 emission nebulæ were catalogued. These objects at first appeared to outline the spiral structure very well, but later work has shown that their interpretation is not easy. Arp (*Astrophys. J.*, 139, 1045; 1964) has made a detailed discussion of the problem. The distribution of the brightest stars must also be considered. Direct photographs have shown that the best representation of the spiral structure is obtained if it is assumed that the Nebula is tilted at an angle of 16° to the line of sight. When attempts are made to fit the emission nebulæ to this picture difficulties arise. There does not seem to be any tilt angle which, when allowed for, will give a picture of the emission nebulæ looking like a continuous spiral curve. A much better fit is obtained if the angle of tilt is 11° to the line of sight. Dr. Arp suggests that the whole plane of the Nebula is warped, with a tilt of 16° for the side more distant from us, and for the central regions, and a tilt of 11° for the near-side regions. On this picture the emission nebulæ form a complete spiral. There is evidence that the warping is caused by the companion elliptical galaxy, *M* 32.

Research Scholarship in Environmental Engineering

APPLICATIONS are invited from graduates in engineering or physics who wish to undertake research on problems associated with the study and production of comfortable environmental conditions in buildings. The award is made by the Heating and Ventilating Contractors Association and has a value of £800 per annum. The award would be made, in the first instance, for a period of one academic year, but is renewable subject to satisfactory progress. Holders of the scholarship would be permitted to submit their work for a high degree where university regulations permit. Further information and a form of application can be obtained from the Secretary and Clerk to the Governors, National College for Heating, Ventilating, Refrigeration, and Fan Engineering, Borough Polytechnic, Borough Road, London, S.E.1.

Chelsea College of Science and Technology

In accordance with the decision of the University Grants Committee, the Governing Body of Chelsea College of Science and Technology, with the approval of the Academic Advisory Committee, has in anticipation of the grant of University Status to the College conferred the title of professor on the following heads of Departments: Dr. A. H. Beckett (pharmacy), Dr. S. E. Dicker (physiology and pharmacology), Dr. J. F. J. Dippy (chemistry), Dr. K. W. Keohane (physics), Mr. A. E. Ludlam (mathematics), Dr. R. D. Purchon (botany and zoology). In addition, the title of reader has been conferred on Dr. W. E. Smith (geology).

University News: East Anglia

Dr. D. C. Champeney, at present lecturer in physics in the University of Birmingham, has been appointed lecturer in physics.

London

Dr. Jack Tizard, of the Social Psychiatry Research Unit of the Medical Research Council at the Institute of Psychiatry, has been appointed to the chair of child development at the Institute of Education. The following have been appointed to readerships: Dr. P. W. M. Jacobs (physical chemistry at Imperial College of Science and Technology); Dr. K. B. Roberts (physiology at the London Hospital Medical College); Dr. A. M. James (physical chemistry at Queen Elizabeth College); Dr. M. H. Quenouille (statistics at the Imperial College of Science and Technology); Dr. E. A. Ash (electrical engineering at University College). The following titles have been conferred: professor of pædiatrics, on Dr. J. P. M. Tizard, in respect of his post at the Institute of Child Health; professor of social institutions, on Mr. O. R. McGregor, in respect of his post at Bedford College; reader in physics, on Dr. D. W. O. Heddle, Dr. C. Henderson and Dr. R. E. Jennings, in respect of their posts at University College; reader in biochemistry, on Dr. M. W. Neil, in respect of his post at the London Hospital Medical College; reader in human environment, on Dr. I. W. Cornwall, in respect of his post at the Institute of Archæology.

Southampton

Prof. G. M. Lilley, professor of fluid dynamics at the College of Aeronautics, Cranfield, has been appointed to the chair of aeronautics and astronautics. Mr. P. Hammond, Fellow and director of studies in electrical sciences in Pembroke College, Cambridge, has been appointed to the chair of electrical power engineering. Dr. H. B. Griffiths, senior lecturer in mathematics in the University of Birmingham, has been appointed to the second chair of pure mathematics. Mr. J. H. Smith, lecturer in social science in the London School of Economics, has been appointed to the chair of sociology. Prof. E. J. Richards, professor of aeronautics in the University, has been appointed to the new chair of applied acoustics and the directorship of the Institute of Sound and Vibration Research. The following appointments to lectureships have been made: Dr. R. A. East (aeronautics and astronautics); Dr. R. Baker, Dr. M. C. Flowers, Dr. N. B. H. Jonathan, Mr. J. M. Mellor and Dr. J. S. Wood (chemistry); Dr. M. E. Barton and Dr. B. S. Smith (civil engineering); Mr. J. D. E. Beynon (electronics); Mr. E. W. Haddon (mathematics); Dr. J. G. McEwen (physics); Dr. A. Crowe (physiology and biochemistry); Dr. T. Priede and Mr. P. L. Tanner (sound and vibration research); Miss D. M. Shepherd (sociology and social studies).

Announcements

Dr. Frank Dollin, chief turbine engineer, C. A. Parsons and Co., Ltd., has been awarded a Thomas Hawksley Gold Medal by the Institution of Mechanical Engineers, for his paper, "Some Design Problems Arising in the Development of Very Large High-speed Turbines". The award, established in 1908, commemorates the eminent engineer, Thomas Hawksley, who was president of the Institution in 1876 and 1877, and is given for the best paper published by the Institution in the year.

The Bulletin *Science East to West*, formerly known as *Russian Technical Literature*, issued by the Directorate for Scientific Affairs of the Organization for Economic Co-operation and Development, covers scientific and technical literature from East Europe, the U.S.S.R., and China and Japan. The January 1964 issue (No. 13) includes an article on the production and utilization of energy in the U.S.S.R., a list of recently published translations of books from Russian and details of courses available in the Russian language.

A discussion meeting on "The Future of Chemical Publications" will be held by the Chemical Society in the University of Nottingham during September 22–24. Further information can be obtained from the General Secretary, the Chemical Society, Burlington House, Piccadilly, London, W.1.

A symposium on "Hydroxycinnamic Acids and Related Compounds", arranged by the Phytochemical Group (formerly the Plant Phenolics Group), will be held at the University of Sheffield during September 22–23. Further information can be obtained from A. H. Williams, Research Station, Long Ashton, Bristol.

A scientific meeting of the Hospital Physicists' Association will be held, to celebrate the twenty-first anniversary of its foundation, at St. Bartholomew's Hospital during September 24–26. Further information can be obtained from Miss K. Smith, Hospital Physicists' Association, 6 Paddington Street, Marylebone High Street, London, W.1.

A conference on "Many-body Problems", arranged by the Institute of Physics and the Physical Society, will be held in the University of Manchester during September 22–24. The programme will include sessions on many-body problems in: atomic physics; molecular physics; nuclear physics; solid-state physics; polymers; liquids. Further information can be obtained from the Administration Assistant, Institute of Physics and the Physical Society, 47 Belgrave Square, London, S.W.1.

A short course on "Practical Noise Control", arranged by the Institute of Sound and Vibration Research, will be held in the University of Southampton during September 16–18. The course will consist of ten lectures, supported by laboratory demonstrations, and will cover acoustics, noise measurements, subjective assessments, technical principles of noise control and medical and legal implications. Forms of application and further information can be obtained from Dr. T. Priede, Institute of Sound and Vibration Research, the University, Southampton.

Erratum. The author of the book *Planetary, Lunar, and Solar Positions* A.D. *2 to* A.D. *1649 at Five-day and Ten-day Intervals*, which was reviewed by Dr. R. H. Garstang on p. 943 of the June 6 issue of *Nature*, is Bryant Tuckerman and not Bryant Zuckerman as published.

THE NATIONAL PHYSICAL LABORATORY

THE National Physical Laboratory held its annual open week during May 25–29, and 175 items were on display in the nine Divisions of the Laboratory. Some 3,000 visitors attended during the two main open days, while on the final day visits were made by more than 1,000 sixth-form pupils from more than fifty schools. No lectures were given this year but two new films were shown to visitors: one, "Ship Shape", dealt with the work of the Ship Division; and the other, "Precise Measurement in Engineering", dealt with the work of the Standards Division.

The visitors were able to inspect for the first time two new buildings in which have been rehoused the two newest Divisions, Autonomics and Basic Physics, which previously were scattered in a number of small, often temporary, buildings within the grounds of the Laboratory.

An exhibit which attracted much interest in the Basic Physics Division concerned the behaviour of solid carbon dioxide when subjected to very high pressure. Some time ago the group working on the behaviour of materials when subjected to very high pressures discovered that carbonyl sulphide can, like carbon disulphide, be transformed into a black, stable, semi-conducting polymer at high pressures. As a preliminary to an attempt to produce this polymer from solid carbon dioxide and carbon disulphide it was decided to investigate the behaviour of solid carbon dioxide under high pressure. It was then found that above a certain pressure, in the neighbourhood of 35 kilobars, the carbon dioxide underwent a change of phase and its specific resistance dropped by several orders of magnitude. The exact values of the pressure at which this change takes place have yet to be determined and little is yet known about the properties of the resulting substance. This high-pressure form, however, is not stable, and when the pressure is removed the carbon dioxide reverts to its normal state. Subsequent experiments with carbon disulphide at lower temperatures than those used to produce the stable polymer have shown that a change to an unstable conducting phase can be produced by high pressures.

The Basic Physics Division was also exhibiting the results of its latest work on sub-millimetre stimulated emission sources. The apparatus used for this work consists essentially of a 50-kV, 2·5-μsec pulsed gas discharge between two plane mirrors, and power is extracted by a dielectric film (thin compared with the wave-length of the emission) set at 45° to the optical axis of the mirror system. This arrangement provides a resonator of reasonably high '*Q*' and a Fabry–Perot interferometer of high resolving power; the addition of a third mirror provides a Michelson interferometer of lower resolving power for wide-band spectroscopy.

Strong, narrow lines with peak powers of the order of watts and wave-lengths 20–120μ were observed to be emitted by laser action when water vapour was introduced into the resonant cavity provided by the mirror system of the interferometer. The introduction of vapour containing the cyanide radical CN (from hydrogen cyanide, methyl cyanide or ethyl cyanide) gave rise to a strong stimulated emission at 336·5μ with a peak power of the order of 10 W. This discovery has interesting possibilities for the long-standing problem of generating sub-millimetre waves of reasonable power. A possible practical importance arises from the closeness of the new line to the most favourable wave-length in the sub-millimetre range to minimize absorption attenuation due to atmospheric water vapour, which is in the region of 345μ.

In the Autonomics Division building, visitors were able to see work on character recognition, which is concentrating on two main problems. One is the recognition of poorly printed numerals, such as may be produced by typewriters or cash registers, and the other is the recognition of printed text.

The systems of character recognition being investigated are based on the premise that characters consist of a limited number of features (for example, straight lines, curves, intersections and line endings) grouped and joined together in various spatial arrangements to form the characters of a set. Two-dimensional autocorrelation techniques are used to deduce the orientation and relative positions of these features and groups of features, and these in turn determine the identity of the characters.

For the recognition of numerals the output from a conventional flying-spot scanner is fed to three serially connected delay lines, and tapping points along the delay lines are used to sample the stored wave-forms. The output of a multiplier associated with each group of sampling points is integrated; the outputs from the integrators indicate the extent to which each feature is contained in the scanned character, which is then identified by a likelihood comparison with similar sets of characters using a linear decision network. The apparatus demonstrated is the result of a two-year design investigation which has shown the feasibility of constructing a practical system of character reading. Its main advantages are a high reading rate—more than 1,000 characters per second—and tolerance of a wide range of print quality and of the orientation of the character within the field being scanned. Its print quality tolerance is largely due to the use of analogue signals.

The recognition of text presents additional problems, one of the most important being the difficulty of segmenting words into individual characters, particularly if the quality of the printing is poor. An experimental system for the reading of text without prior segmentation, at present restricted to the ten most frequent letters of the alphabet (e t a o n r i s h d) in one size and style, but with variations in the quality of printing, is being simulated on the *ACE* computer. This system is shown schematically in Fig. 1. A line of text is scanned and stored in the form of a binary pattern, on which are then performed auto-correlation transformations similar to those made in the character reading described above. However, in this case the output is not integrated but the positional information is retained in two-dimensional form. This information about the position of features is then, by means of further auto-correlation transformations, searched for the presence of groups describing the familiar alphabetic characters. This results in a sequence of probability scores which are then scanned by a decision aperture to produce a sequence of identifications.

Another new building on view contains the mechanical working laboratory of the Metallurgy Division. The object of this laboratory is to facilitate metallurgical work for the expected requirements of engineering developments during the next twenty years, and to this end work will be directed towards three primary objectives. The first of these is the examination of the large group of body-centred cubic metals in Groups IV, V and VI. These include vanadium, niobium and tantalum, chromium, molybdenum and tungsten, and the body-centred cubic forms of titanium, zirconium and hafnium. They are all of high melting-point and easily contaminated, and special equipment has therefore had to be installed for their proper handling.

The second objective is to exploit the new knowledge of the structure of metals which is arising from the direct observation of dislocations. Earlier work in the Division on the dislocation patterns in iron, and their relation to mechanical behaviour, showed that these patterns may be controlled partly through the purity of the material and partly through the working operations applied during

the course of manufacture, and that the patterns will control many of the more subtle mechanical characteristics. It is therefore planned to examine these effects in more detail using iron and its simpler alloys, since iron and steel seem likely to remain the basis of engineering practice.

The third type of work for which the laboratory is suitable, and which it may be desirable to do in the future, is the preparation and study of bodies composed of mixtures of metallic and non-metallic phases. Important developments have taken place in the production of powders in which the non-metallic phase is uniformly coated by the metallic phase, and these considerably simplify the making of the desired composites.

The equipment on view consists of two rolling mills, a 700-ton extrusion press (Fig. 2), swaging machines, a forging hammer, a wire-drawing bench, together with saws, slitting wheels and similar ancillary equipment. There are two vacuum furnaces of novel design. The larger of these enables a billet for extrusion to be heated to temperatures up to 1,700° C and quickly removed from the furnace without breaking the vacuum in the heating chamber. Small specimens can be heated to temperatures up to 2,400° C in the smaller furnace and quenched into water, again without breaking the vacuum.

Also to be seen in the Metallurgy Division was a universal electron probe microanalyser. The electron probe microanalyser has many applications in metallography since it can be used to explore fluctuations of composition in inhomogeneous specimens and to reveal the differences in composition of phases seen in the microstructure. As developed by Castaing some years ago, it cannot detect elements with atomic numbers below 12 because there are no crystals capable of diffracting the long-wave X-rays characteristic of the lighter elements. Metallurgically important constituents found in industrial alloys (such as oxides, carbides or nitrides) therefore fall outside the range of the analyser.

The foregoing limitation may be overcome by the use of optical line gratings to analyse the radiations from the light elements, but hitherto the diffraction efficiency of these gratings for X-rays has been low because of imperfections in the grating surface produced by the action of the ruling tool. A joint programme of research between the Light and Metallurgy Divisions has produced a development of the Siegbahn-type grating which consists of an optically worked surface interrupted by grooves. The National Physical Laboratory gratings, which have 7,500 lines per in., are manufactured by a process involving the replication and etching of a ruled grating and have a very high diffraction efficiency. They have been used in microprobe analyses and all elements down to lithium have been detected by attaching a grating spectrometer to a commercial microprobe analyser. In addition to metallurgical applications, the new X-ray gratings should be of value for the precise measurement of X-ray wave-lengths, the examination of solar and stellar X-ray emissions observed in outer space, and the elucidation of processes taking place in thermo-nuclear devices.

The Aerodynamics Division had an exhibit dealing with the maintenance of laminar boundary layers in order to reduce the drag of an aircraft, a subject which has for many years been investigated at the Laboratory within the Reynolds number limitation of its low-speed wind-tunnels.

One problem associated with swept-back leading edges is that wedges of turbulent flow originating at the wing root, or from insects accidentally impacted on the leading edge, may cause unlimited span-wise contamination of the outboard laminar boundary layer. Results were shown of a recent Laboratory experiment which has established roughness criteria for this occurrence for comparison with the existing two-dimensional criteria. Ways of limiting such span-wise contamination, and of raising the Reynolds number at which it occurs, have been found and are jointly being investigated at the Laboratory and the College of Aeronautics. The latter work forms part of a flight-research programme, sponsored by the Ministry of Aviation, on a swept fin in which boundary-layer suction is applied through a slitted surface, and aimed at possible applications to the next generation of high-speed swept-wing transport aircraft.

A long-term application of boundary layer control, to a supersonic aircraft of slender planform, could be seen in the 13 ft. × 9 ft. wind-tunnel. A delta wing, with leading edge swept back 76° and with a wholly porous upper surface of sintered steel, is being tested at low wind

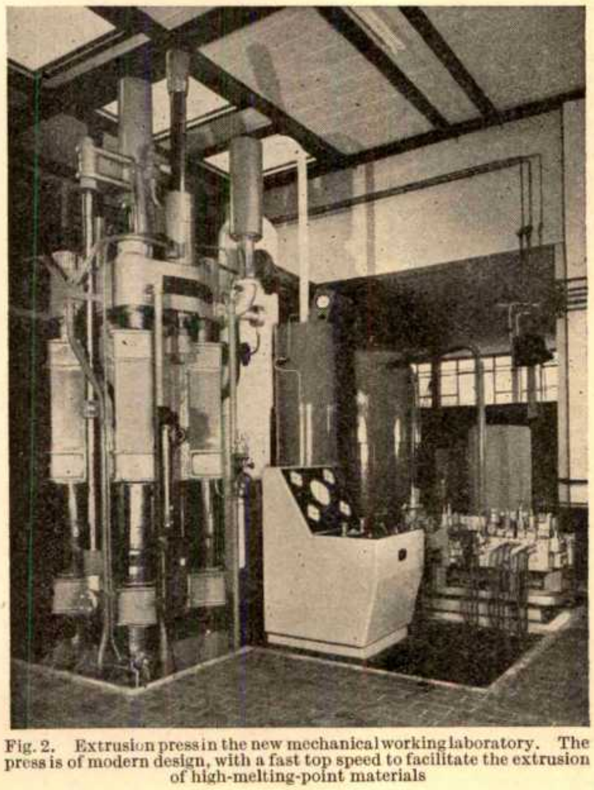

Fig. 2. Extrusion press in the new mechanical working laboratory. The press is of modern design, with a fast top speed to facilitate the extrusion of high-melting-point materials

speeds in order to determine the distributed suction needed to maintain laminar boundary layers over the upper surface in the presence of the three-dimensional flow associated with the very high leading-edge sweep. The interior of the wing is divided into six compartments, and the flow through the surface over each compartment can be controlled independently. The work includes the examination both of attached flow at the leading edge and the leading-edge vortex type of flow which produces a swept attachment line inboard of the leading edge in the vicinity of the highly turbulent vortex. Distributed suction is expected to affect the position of the vortices by eliminating secondary separation.

An interesting exhibit in the Ship Division illustrated the effect of a contaminant on turbulent boundary layers in water. In the apparatus used for this demonstration two identical revolving flanged disks were immersed in identical cylindrical casings, containing equal volumes of water, and the torque exerted by the water on each casing was shown. The addition to one casing of a small quantity of 'Polyox', sufficient to give a concentration of about 30 parts per million by weight, reduced the torque by about 30 per cent. Another contaminant which causes the same effect is guar gum.

Investigations have shown that this reduction in torque is not associated with any delay in transition from laminar to turbulent flow, but the thickness of the turbulent boundary layer is appreciably reduced by the addition of the contaminant. The exact mechanism producing this change has yet to be determined, but it is thought that it is possibly associated with a weakening of the larger eddies in the boundary layer. This effect may explain some anomalous results which have been obtained from time to time in ship hydrodynamic tests, the supposition being that certain algae in the water can act in a similar manner to 'Polyox' or guar gum. These additives can be used to reduce the power required to pump liquids over long distances.

The Ship Division also showed, in its larger water-tunnel, an impressive demonstration of the flow from a fully cavitating propeller (Fig. 3). The conventional marine propeller is designed to minimize the amount of cavitation that occurs at high forward speeds. However, propellers in high-speed craft often cavitate heavily, and under such conditions the mode of operation of the propeller is different from that of the non-cavitating propeller. The growth of large cavities in the wake restricts the mass of water that can effectively be accelerated astern and, in consequence, the thrust and torque of the fully cavitating propeller are reduced in comparison with the equivalent non-cavitating propeller.

Existing design methods developed for propellers which operate with cavities completely covering the suction side of the blade surfaces are now recognized to be inadequate, and attempts are being made to produce an improved design procedure. This improved design method requires, at least, knowledge of the size and shapes of the cavities in the wake downstream from the propeller and attempts are being made to obtain such information from experiments with fully cavitating propellers. It is hoped to be able to correlate this experimental information with a simple theory which will allow future predictions of cavity dimensions to be made. Further progress is thus dependent on the results of experiments, such as that demonstrated, with models designed using approximate estimates for some of the essential factors. In this experiment, the circumferential thickness of the cavities in the wake is measured by using a number of probes spaced in the radial direction and held by a stationary strut in the wake of the propeller.

One of the exhibits in the Radiology Group of the Applied Physics Division was a solid-state spectrometer for α- and β-rays. The requirements of a spectrometer for detecting and measuring the energy of charged particles are: good resolution, that is, the ability to distinguish between particles of closely similar energies; an output proportional to the energy deposited in the detector and independent of the nature of the radiation; a rapid response, allowing high counting rates; compactness; and simplicity. Gas-filled ionization chambers are simple, have good resolution and a linear output; scintillation counters are compact and possess a rapid response. However, solid-state devices possess all the required properties and are replacing ionization chambers and scintillation counters in many applications.

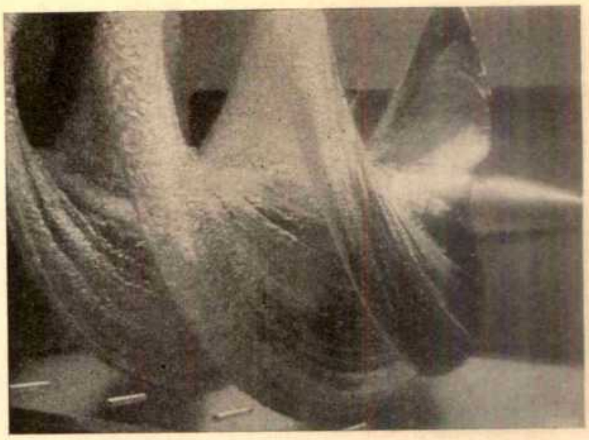

Fig. 3. A fully cavitating propeller in the National Physical Laboratory 44-in. diameter water-tunnel

The signal from a solid-state detector is a quantity of charge produced by ionization and collected by an applied field. To obtain a realistic signal-to-noise ratio combined with rapid collection, the solid must be a semi-conductor. The straightforward 'homogeneous' detector suffers from disadvantages associated with the difficulty of obtaining material of sufficient purity. Junction detectors, which make use of the rectifying junction between *p*- and *n*-type material, are therefore preferred. These are operated with a reverse bias which determines the width of the depletion layer, the sensitive volume of the detector. Junction detectors give good energy resolution, about one order of magnitude better than scintillation counters; very fast response, collection times of the order of 1 nanosecond; and a very thin dead layer.

In the experiment demonstrated a silicon surface-barrier junction detector was being used to measure the α-radiation from a source of americium-241. A similar detector with a wider depletion layer can be used for measurements of β-ray spectra. Future developments that can be foreseen are a fast $4\pi\beta-\gamma$ coincidence system, utilizing solid-state detectors for the β-rays and inorganic scintillators for the γ-rays, and identification of γ-rays from measurements of the photoelectrons ejected from a suitable converter foil.

Exhibits in the Light and Standards Divisions illustrated the Laboratory's responsibilities in the field of standards.

The present primary standard of light is a black-body radiator held at the freezing-point of platinum. While in theory this standard leaves nothing to be desired in accuracy, in practice there has been great difficulty in realizing precisely the theoretical conditions and in achieving good repetition. An alternative approach proposed by the National Physical Laboratory involves the use of a black radiation thermopile, observing all wave-lengths equally, behind a filter which transmits in varying proportions at different wave-lengths in accordance with the spectral sensitivity of the eye. For this measure to be absolute, and hence photometry become a logical branch of radiometry, it is necessary that the filter transmission should be amenable to calibration and that the thermopile be calibrated in terms of known intensities of incident radiation.

As a result of this proposal, the Consultative Committee on Photometry of the Bureau International des Poids et Mesures requested the National Physical Laboratory to organize an international comparison of radiometric scales, as a first step in assessing the possibilities of the proposed method as an internationally agreed substitute for the material primary standard of light. Standards laboratories in seven other countries are participating in this work. Lamps calibrated at the Laboratory for total radiation intensity are being sent to these laboratories for comparison and the results will be reported to the Consultative Committee at its meeting in 1965.

In the Standards Division work is being carried out on the realization of the thermodynamic temperature scale above 175° C, using a method based on the Planck law of radiation. The International Practical Scale of Temperature (IPST) was first defined in 1927 to conform as closely as possible with the thermodynamic Celsius scale as then known. However, recent determinations of thermodynamic temperature above 100° C by gas thermometry have given temperatures higher than those of the IPST, the difference steadily increasing with temperature until it reaches about 1·5° C at the gold point (1,063° C). It is therefore urgently necessary to revise the IPST, or at least to make an authoritative statement of the differences between it and the thermodynamic temperature scale. The Advisory Committee on Thermometry of the International Committee of Weights and Measures is dealing with this problem and the work demonstrated in the Standards Division stems from this Committee's activities.

The apparatus used in measuring temperatures up to the gold point consists essentially of a double monochromator using a prism, followed by a grating, in order to produce a narrow wave-length band at a mean wave-length λ, which can be set accurately. Energy radiated at this wave-length by two furnaces at temperatures T_1 and T_2 is detected by a cooled lead–telluride cell, and the energy ratio R is determined by adjusting the area of the aperture in front of the detector so that equal signals are received from the two furnaces. The energy ratio is then given by:

$$R = \frac{\exp\left(\frac{C_2}{\lambda T_1}\right) - 1}{\exp\left(\frac{C2}{\gamma T_2}\right) - 1}$$

where C_2 is the second constant of radiation in the Planck formula. Since λ is known, T_2 can be determined in terms of T_1. When the most recent assessment of the value of C_2 from atomic constants is used (that is, 0·014 388 4 m deg) the thermodynamic temperatures measured in the experiments are proving to be in agreement with those given by gas thermometry up to 800° C, but somewhat lower above this temperature.

The realization of the temperature scale above 1,063° C is normally based on the use of a visual optical pyrometer. By using a rotating sectored disk to achieve known energy ratios and a photomultiplier cell as a detector the Laboratory is aiming to achieve a ten-fold improvement in accuracy over the visual method. The apparatus on show used at its lower temperature source radiation from a graphite black-body cavity held at 1,063° C and the higher temperatures were produced by special black-body lamps, developed jointly by the Laboratory and the Hirst Research Centre.

Another type of work done by the National Physical Laboratory was also illustrated in the Standards Division, where visitors were able to see new force-measuring columns for 50 tonf and 500 tonf maxima which satisfy the requirements of Grade I proving devices of British Standards 1610 : 1964 for loads ranging from their maximum to less than one-fifth maximum, respectively. These instruments, developed in the Division, have the advantages of being robust, simple in design and accordingly of relatively low manufacturing cost. They may be used for the verification of all types of compression testing machines. The Standards Division also showed an exhibit dealing with the re-definition of the yard and pound as a result of the new Weights and Measures Act which came into force on January 31, 1964. Under this Act the yard is defined as 0·9144 international metre and the pound as 0·453 592 37 international kilogramme.

Open days provide a valuable opportunity for National Physical Laboratory staff to demonstrate the results of their latest work to other scientists and industrial users and at the same time for the staff to widen the already extensive contacts that they have with such people. Visitors are given a cordial welcome and it is hoped that even greater numbers will be able to come to Teddington in 1965 when the open days will take place in the week beginning May 17. Requests for invitations should be addressed to the Director, National Physical Laboratory, Teddington, Middlesex.

A. CHINNECK

NATIONAL LABORATORIES IN INDIA*

By A. RAHMAN, DR. A. GHOSAL, N. SEN, N. R. RAJAGOPAL, MRS. S. DAS GUPTA, S. H. M. HUSSAINI and A. K. ROY

Survey and Planning of Scientific Research Unit, Council of Scientific and Industrial Research, New Delhi

THE post-war period saw a rapid growth of scientific research in India. The Council of Scientific and Industrial Research which was set up in the early 'forties set up a chain of thirty-one laboratories during the period 1946–63. These laboratories were committed to the task of solving industrial and other national problems through research and development, by way of assessing correctly the quality of raw materials available in the country and improvising their proper use. Since industrial research always faces crucial problems in basic science, proper stress was also given to basic research. An investigation has been made by the Survey and Planning of Scientific Research Unit to take a stock of the development of these laboratories by making a statistical appraisal of the research inputs, namely, expenditure, scientific personnel, scientific equipments, personnel and the research outputs in different laboratories.

Expenditure

The total expenditure of the Council of Scientific and Industrial Research increased about sixteen times during the period 1946–62 from Rs. 5·2 millions in 1946–47 to Rs. 81·2 millions in 1961–62. In 1961–62 the recurring expenditure formed 64 per cent of the total expenditure, which again was 17 per cent of the total Government expenditure on scientific research in India (Rs. 469 millions)†.

A detailed statistical investigation has been carried out for the period 1954–62. During this period the expenditure in the laboratories increased rapidly. The increase was very great at the National Metallurgical Laboratory where the expenditure in 1961–62 was eight times that in 1954–55. In other developed laboratories the increase in expenditure was at least 100 per cent. High capital intensive laboratories are the National Aeronautical Laboratory, the National Metallurgical Laboratory, the Central Fuel Research Institute, the Indian Institute of Petroleum, the Central Mining Research Station, the Central Mechanical Engineering Research Institute, the Central Glass and Ceramic Reearch Institute, the Regional Research Laboratory, and the Hyderabad and Public Health Engineering Research Institute, where the capital expenditure formed more than 40 per cent of the total expenditure. High capital expenditure in these laboratories is primarily due to pilot plants and costly equipment. The trend in total expenditure in the developed laboratories with expenditure exceeding Rs. 3 million in 1961–62 is given in Table 1.

---

* A comprehensive monograph will be published shortly.

† "A Study of Government Expenditure on Scientific Research", *J. Sci. Indust. Res.*, **22**, 479 (1963).

Table 1. TOTAL EXPENDITURE IN A FEW IMPORTANT LABORATORIES

	Rs. millions	
Laboratory	1954–55	1961–62
National Metallurgical Lab.	1·08	8·78
Central Fuel Research Inst.	2·29	5·61
National Physical Lab.	2·40	4·47
National Chemical Lab.	2·01	4·07
National Aeronautical Lab.	—	3·66
Central Drug Res. Inst.	1·23	3·64
Regional Research Lab. (Hyderabad)	—	3·14
Central Food Tech. Res. Inst.	1·01	3·11

Most of the developed laboratories spent about 50–60 per cent of the total recurring expenditure on salaries and allowances to staff, out of which 9–15 per cent was incurred on salaries of administrative staff. The percentage of total staff expenditure to total recurring expenditure has been increasing in most of the developed laboratories, and it is estimated that if the present trend continues, then by 1970–71 it will be of the order of 80 per cent in many of them.

Most of the specialized equipment and pilot plants have to be imported from abroad. Consequently the work of the laboratories has suffered greatly from the acute shortage of foreign exchange in the country. Foreign exchange spent in a few important laboratories over 1957–62 was as follows: the National Metallurgical Laboratory, Rs. 4·1 million; the Central Fuel Research Institute, Rs. 3·2 million; the Central Glass and Ceramics Research Institute, Rs. 1·1 million; the Regional Research Institute, Rs. 1·8 million; and the National Physical Laboratory, Rs. 1·2 million.

Personnel

A detailed analysis of staff structure in different laboratories has also been made for the period 1954–63. The staff in the laboratories increased from 2,682 in 1954 to 9,014 in 1963, so that the overall rate of growth per annum was roughly 14 per cent. Only two laboratories (the Central Fuel Research Institute and the National Physical Laboratory) had staff strength above 1,000; three (the National Chemical Laboratory, the National Metallurgical Laboratory, and the Central Food Technological Research Institute) had staff strength between 500 and 1,000; five (the Central Mining Research Institute, the Central Glass and Ceramics Research Institute, the Public Health Engineering Research Institute, the Regional Research Laboratory, Hyderabad, and the National Botanical Garden) had staff strength between 300 and 500; and the rest had staff strength below 300 in 1963.

In 1954, out of a total staff of 2,682, 662 (25 per cent) were scientists and technologists directly connected with research, 1,276 (47 per cent) were auxiliary technical persons, assisting the research personnel by performing various technical and skilled work, and 744 (28 per cent) performed administrative work. In 1963, 3,165 out of a total strength of 9,014 were scientists or technologists directly connected with research; 39 per cent were auxiliary technical personnel and 26 per cent were administrative staff. The distribution of research, auxiliary technical and administrative staff varied from laboratory to laboratory depending on its stage of development and nature of work. Technological laboratories employed comparatively more auxiliary technical persons and less research scientists than the laboratories concentrating more on fundamental work.

The number of supporting staff per scientist has been calculated for different laboratories by dividing the sum of auxiliary technical and administrative personnel by the number of research scientists and technologists. The highest figure (5·3) is recorded at the National Physical Laboratory; this figure is high (greater than 3) in technological laboratories like the National Metallurgical Laboratory, the Central Fuel Research Institute, the National Botanical Garden, and the Public Health Engineering Research Institute, while it is low (less than 2·5) in laboratories like the National Chemical Laboratory, the Central Drug Research Institute, the Central Food Technological Laboratory and the Regional Research Laboratory, Hyderabad. There are, however, a few laboratories (for example, the Central Building Research Institute, the Regional Research Laboratory, Jammu, and the Central Leather Research Institute) which do not carry out so much fundamental research, but have a low figure for this ratio.

A three-way classification of scientists by age, qualifications and salary has been examined for the year 1963. Qualifications were broadly grouped under three groups, namely: (1) B.Sc.s and diploma holders in technology; (2) M.Sc.s in general science and graduates in engineering and medicine; (3) doctorates (Ph.D., D.Sc., M.D., etc.). Out of 3,165 scientists about 50 per cent are less than 30 years of age, 35 per cent are in the age-group 30–40, 12 per cent in the age group 40–50 and only 3 per cent are above 50. Out of all scientists 51 per cent are B.Sc.s and diploma holders in technology, 35 per cent are M.Sc.s and 14 per cent hold doctorates. An interesting finding from this survey is that remunerations vary widely among persons having similar qualifications and experience. Thus a Ph.D. in the age group below 50 may get any salary between Rs. 300 and Rs. 2,000 with a mode in the pay-range Rs. 500–1,000; a Ph.D. of more than 50 usually receives a higher salary. The same holds true for M.Sc.s and graduates in engineering and medicine, though for them the modal pay group is Rs. 300–500 for those aged below 40, and Rs. 500–1,000 for those aged above 40. About half the B.Sc. scientists are aged below 30, and most of them have monthly pay below Rs. 300.

So far there is no financial incentive for working scientists to enhance their academic qualifications. Initial qualifications are taken into consideration for determining a scientist's status on entry, and subsequent qualifications earned during service do not play a significant part in his future promotions and pay increases. Since seniority is also taken into consideration for future promotions, it is likely that many B.Sc.s may occupy more responsible positions in the laboratory in future.

Cost per Scientist

A detailed analysis of the cost per scientist has been made for 1961–62 for different laboratories. Highest figures were recorded at the National Aeronautical Laboratory (Rs. 159,000 per annum) and the Indian Institute of Petroleum (Rs. 146,000 per annum)—these figures are comparable to the overall figure for the United States for 1960 (Rs. 173,000)*. At the National Aeronautical Laboratory the high cost is primarily due to the high cost of equipment and high average salaries of trained workers who are scarce in this field in India. At the Indian Institute of Petroleum the high cost is also ascribed to the high remuneration of the foreign scientists. In some of the old-established laboratories like the Central Fuel Research Institute, the National Chemical Laboratory, the Central Leather Research Institute, the Central Building Research Institute, and the National Physical Laboratory, the cost per scientist is comparatively low (less than Rs. 30,000 per annum), while in a few laboratories like the National Metallurgical Laboratory this figure is somewhat high due to heavy expenditure on pilot plants. It appears that in the laboratories engaged in the fields in which there is an abundance of trained workers and low cost chemicals and equipment, the cost per scientist is low. The figures for cost per scientist calculated in respect of the national laboratories will help any organization in the country to gain an idea of the expenditure required for setting up a laboratory in any of the mentioned fields of work.

---

* *Reviews of Data on Research and Development* (National Science Foundation, Washington), No. 33, 6 (April, 1962); 1 dollar = Rs. 4·77.

Research Output

In the absence of a suitable measure of research output a study has been made of the research papers produced in different laboratories during the past ten years. In some of the developed laboratories the number of papers has gone down during the past five years or so, due to greater emphasis on the exploitation of the research results in industry. The work in national laboratories is responsible for the framing of many specifications by the Indian Standards Institution in recent years.

Perspective Plan

The Council of Scientific and Industrial Research is drawing up a perspective plan for the expenditure of laboratories in future, in the Fourth (1966–71) and Fifth (1971–76) Five Year Plan periods, on the basis of information gathered for the study referred to here. While arriving at the future estimates of different items, salaries to scientific personnel, salaries to administrative personnel, expenditure on chemicals, equipment, capital equipment, etc., for different laboratories, the rate of growth which was registered during the period 1954–63 will be taken into consideration. In most of the cases it will be assumed that these rates will continue in future, especially due to the under-developed nature of the country, though in a few cases it is necessary to take a view of the future rate of growth on *a priori* consideration. It has been found that most of the developed laboratories have been showing stationary rates of growth during the past ten years or so, particularly for the items of a recurring nature—these rates of growth will be assumed for the future also. For items of a capital nature it is really not possible to have a uniform rate of growth. The investigation also raises the problem of the size of the laboratory, interbalancing of resources and the organizational pattern of research—these are being studied.

THE GULLAND LABORATORY: ARTHUR D. LITTLE, LTD.

IN Britain more than 99 per cent of scientific and technical research is carried out by the universities, industrial laboratories, and the co-operative research associations. Since the War, however, research undertaken by an independent organization on behalf of a client or sponsor on a cost basis has begun to make its mark in Great Britain. This type of research is known as 'sponsored' or 'contract' research, these terms having originated in the United States where the selling of research facilities by independent organizations has reached tremendous proportions since the early 1940's.

The rapid development of sponsored research in the United States since the War was due partly to the realization of the importance of research to industry in the immediate post-war years and partly to the American point of view that industry—and not the Government—should be responsible for its own research and development. This combination of factors created a need for facilities to provide industry with a confidential service offering scientific, technical and economic assistance. This need was met by the setting up of the non-profit-distributing research institutes, some of which are now world famous. In addition to these non-profit institutes there is a host of commercial laboratories in the United States undertaking contract research, but only Arthur D. Little, Inc., in Cambridge, Mass., is comparable in size with the non-profit research institutes.

Established in 1886, Arthur D. Little, Inc., is now an international organization, employing a staff of about 1 400 and offering research, development, engineering and management services to industry, governments and banks throughout the world. There are offices and laboratories in many cities in the United States, and in Europe, Canada and Mexico. It has carried out some 70,000 projects during its seventy-eight years of operation.

In Great Britain the advance of sponsored research has been less spectacular than in the United States but nevertheless significant. One of the newest laboratories of this type is the Arthur D. Little Research Institute, which was formed in 1956 at Inveresk, near Edinburgh, in the laboratories previously operated by the Institute of Seaweed Research. It is a non-profit-distributing organization, which works in association with, but is not a part of, Arthur D. Little, Inc., of Cambridge, Mass. It is unique in undertaking only oriented long-range research, which is aimed at finding new spheres for possible exploitation by industry and is not normally concerned with sponsors' immediate problems. Present fields of investigation include the chemistry of cellulose and other polysaccharides, synthetic carbohydrate chemistry, organic sulphur and phosphorus chemistry, biochemistry and biophysics, synthetic high polymer research, metallurgy and various aspects of physical chemistry.

With the growing realization that research is of vital importance to industrial progress and increased productivity, there is now a demand in Great Britain for the full range of services offered by Arthur D. Little, Inc., in the United States. Consequently, in 1963, Arthur D. Little, Ltd., a wholly owned British subsidiary of Arthur D. Little, Inc., was activated to put the full resources of Arthur D. Little, Inc., at the disposal of firms in Britain. The London office of the new Company is specializing in technical, economic and management services for industrialists who require up-to-date knowledge of technology, markets and industrial trends. Such services include guidance in increasing production, diversification, evaluation of research and development, etc.

At Inveresk, the Gulland Laboratory, originally used by the Institute of Seaweed Research as a semi-technical laboratory, has been rebuilt and equipped by Arthur D. Little, Ltd., to provide facilities for applied research in chemistry and allied sciences, including food technology, pharmacology, and new product development. Unlike the Research Institute, the new building, with a laboratory space of 4,500 sq. ft., is equipped for short-term, confidential work for clients.

The redesigned Gulland Laboratory was officially opened on July 1 by Lord Todd, professor of organic chemistry in the University of Cambridge.

THE INFORMATION EXPLOSION

By Dr. M. P. BARNETT
Institute of Computer Science, University of London

SCIENTIFIC and engineering research throughout the world costs the equivalent of billions of pounds. This expenditure creates information. The volume of books, periodicals, reports, manuals and other publications is exploding. Money and research can be dissipated on experiments which have been done already, perhaps in a neighbouring laboratory, if those who need the answer to a question cannot determine if the question has been answered previously, and if it has been, where the answer is reported. One statistic should be enough to stress the problem's magnitude. Two million scientific and technical articles are published annually throughout the world. To find out what is known about some technical matter can be expensive; but it can obviate experiments of still greater cost and bring financial returns of even greater extent. The time-factor can be vital in medicine, commerce and defence. The value of information is recognized in the United States and in the U.S.S.R. In the United States several hundred million dollars are now spent annually on the information flow, and while the rouble expenditure on corresponding activities may not be publicized so widely, it is certain that the U.S.S.R. has deployed considerable talent and effort on this problem.

Some of the methods that are being used by the engineering community in the United States to deal with the information explosion were described in London during June 29–July 2 by Mr. Bart Holm of the Du Pont Corporation. He spoke to various audiences of research managers, engineering personnel and technical information officers at the request of the Institution of Chemical Engineers, who must be congratulated for organizing the meeting. Mr. Holm gave to these three audiences a virtuoso performance of theme and variations—the polished product of an environment in which things get done, enthusiastically, with ample financial support, in the context of a technology that is advancing on every front.

I returned recently from the United States, and I find the Transatlantic contrasts in this as in other fields rather striking. In the United States, the problem of the information explosion has formed the subject of a report of the President's Science Advisory Committee. Congressional committees are aware of the problem, and even if individual politicians may seem to use particular suggested solutions as cases which it may be expedient to support, their efforts contribute to a forward-going movement, in which the pluralistic structure of American society ensures that all good ideas get ample airing. The Defense Department, the National Institutes of Health and National Library of Medicine and the National Science Foundation maintain extensive information collection, cataloguing and reporting projects, and support many more in universities and industry.

The technical problems which are relevant to this work are very diverse. Library design and operation form ample subjects for study by the methods of operational research, and for mechanization by computers and by special purpose equipment. Improving the standard of technical presentation needs increased attention by schools and colleges. Full-time technical writers are in the ascendancy in many quarters. The literature is swollen not just by the desire to communicate information that its producer thinks is useful. Ego satisfaction, academic promotion, grantsmanship and managerial competition contribute to the volume of both the published literature of books and journals and the sub-literature of reports and memoranda. High quality and elaborated typewriters, multilith machines and, in the offing, phototypesetting (with or without the computer's aid) increase the ease and quality with which in-house documents can be produced. Indexing, abstracting and cataloguing the literature for current awareness and for subsequent literature searches occupies many highly trained personnel, and is itself the subject of extensive research. Computers are being used as powerful aids in some of the routine clerical chores associated with such work, though attempts to use computers to do the actual indexing do not seem to hold out much promise for the near future. Computers are being used to obtain lists of citations to material that has been indexed, and which is sought by specification of index terms. Documents once identified are obtained for use in various ways, including copying of full-size originals, microfilm viewing and preparing full-size copies from microfilm. Still further types of information processing machine are on the horizon.

Educational programmes are being developed to train personnel in the new techniques of information handling. Some of the efforts to secure professional status for this new field of endeavour tend to weaken the case rather than to strengthen it. As in other newly developing fields, a considerable amount of material is produced which is rather weak. There is to some extent a repetition of the social scientist's practice of creating excessive jargon. By and large, however, the picture in the United States is one of general progress in information science that is being helped by, and in turn helps, the general advance of a dynamic technology.

ADVANCEMENT IN COKE TECHNOLOGY

THE twentieth annual report of the British Coke Research Association has been issued recently, shortly after the publication of a special report on work carried out at the Coke Research Centre, Chesterfield, during the five-year period since it was opened by the Duke of Edinburgh. During this time, the Centre has been widely recognized throughout the world as an established authority in its field. This comprises a wide range of research activity from studies of atomic structure to commercial scale operations. Indeed, the Association had its origins very much prior to the Second World War in two research committees, namely, the Midland Coke Research Committee operating in the Department of Fuel Technology of the University of Sheffield, and the Northern Coke Research Committee, still in being, which has always operated from research laboratories associated with the Chemistry Department of King's College, Newcastle (now the University of Newcastle). The latest reports of the Association describe full-scale production work on the 10-ton oven at Chesterfield, as well as investigations at the plants of member organizations. The record over the years is thus truly an achievement in the union of science and practice.

Advances in coke technology must have an important bearing not only on the iron-making industry but also on domestic and other industrial needs, for the technical possibilities of the application to any given requirement of solid, liquid or gaseous fuel are always present. Imported fuel is relatively cheap at the moment and the position of coke in an economic sense is naturally associated with that of coal. Fortunately with regard to the latter, with the foreshadowed increases in the world requirements for fuel, and particularly the increasing demands for electrical power which are not in the foreseeable future likely to be overtaken by the supply of atomic energy, some stabilization of the demand for coal would appear to be probable. Further, coal mines cannot be interrupted in production without serious loss, and if shut down for lack of demand valuable natural resources may be lost for ever. Accordingly, any contribution to the amelioration of the fuel and power position from technical efficiency in the manufacture and utilization of coke must be of prime importance.

Turning to the Director's Report for 1963, the objectives of the research programme relate to the continued furtherance of the investigation of the character of the coke as affected by the composition and preparation of the charge, and the treatment received in the coke oven. The programme also covers certain items of special interest to the outside world such as the abatement of pollution of air and water, and the uses of oven coke in domestic appliances. Of particular interest to the iron and steel industry is the search for new methods of making blast-furnace coke.

Of the high spots that may be selected from the account of the five years' achievements, it is noteworthy that the small and large experimental ovens gave performances that correlated with those of commercial plants, thus justifying the faith of the early protagonists of the scheme, who were practical men. The many factors that determine the satisfactory composition and condition of the coal blend charged to the oven have been meticulously explored, and the preferable practice determined in relation to such factors as bulk density, moisture, particle size and the use of additions such as coke-oven breeze, filter cake, hard coke-oven pitch, char, iron ore and low-volatile non-coking coals, all having been assessed on a practical scale as to their effects on the quality of the resultant coke.

Similarly, in regard to carbonizing conditions, the rate of carbonization had pertinent effects on rate of throughput and on the contents of hydrogen and sulphur in the coke. The rank of the coal would be expected to be of considerable importance, and the degree of soaking applied to the charge was a factor of economic significance. The addition of heavy petroleum oil had promised earlier to be advantageous in coke manufacture, but in point of fact the main advantage resided in some enrichment of the gas made. The outcome was a reduction in the weight of dry coal carbonized per unit volume of coke-oven space per hour.

A useful point of interest to the domestic user of coke for space heating is the effect of size, shape and ash of the coke on the performance of a domestic boiler. The size of coke within the range ¾–1¼ in. mattered little, but the larger sizes were slower in reaching maximum output. The best repeatability occurred with a size range of ¾–1 in. For those who wish to know how best to sustain satisfactory banking conditions at night in their appliances there is an upper limit to the desirable size of coke used. With coke above 1¼ in. combustion over 10-h periods could only be maintained within a relatively small range of thermostat settings. A good reactivity of the coke, that is to say, a tendency to give a bright fire quickly, was preferable, and as it increased combustion could be maintained at progressively lower outputs. Similarly, a reduction in size from 1¾–1 in. to ¾–½ in. brought about a progressive drop in minimum rate of output and hence in the minimum intensity of combustion and degree of aeration practicable.

Conclusions having an important bearing on the suitability of coke both as a metallurgical and domestic fuel were provided from investigations involving the technique of electron-spin resonance. It was shown that a significant fraction of the sulphur reacting with carbon was retained as complexes stable up to 900° C and even higher. In the range of temperature 500°–900° C similar complexes were of the nature of surface sulphides, and their formation was influenced by the available surface of the carbon concerned. Some 50–60 per cent of the total sulphur in the coke was so composed, a pertinent pointer to the difficulties to be overcome in removing sulphur from coke. It is most interesting to note in this context that carbonization at temperatures much higher than those used in conventional practice might offer possibilities of a reduced sulphur content of the coke as well as an increased rate of throughput. It should not be beyond practical possibilities for an economic solution of this problem to be achieved, although it would obviously require time for development and application. The Association has started what promises to be a most interesting investigation in this field.

Of the research work dealt with in greater detail in the Director's report, a subject of considerable interest to the domestic user of coke has been the question of producing reactive coke in coke ovens by inclusion in the charge of 0·75 per cent of sodium carbonate. The operattional conditions required to make this practicable were worked out at a member's plant.

In the Fundamental Studies Laboratory, encouraging success was achieved during the year in the development of experimental methods for use in studies of the fissuring of coke during carbonization; the stress or strain concerned in the fissuring of coke was determined by means of electrical-resistance strain gauges, another successful application of a technique now widely applied in engineering research. For the measurement of stress transmission in coke the determination of the resonant frequency of longitudinal elastic waves in a small cylinder of the coke has been used. The approach by this means is somewhat complicated because the material being examined is both porous and heterogeneous. Preliminary indications were that the mean stress velocity varied with the shatter index of the coke, which is at present regarded as the criterion of a serviceable product. These more basic investigations of fissuring are being followed up in the Applied Studies Laboratory by work on both a laboratory and a pilot scale.

Active development of research on air and water pollution is at present being undertaken. The wastes from coke-oven plants contain a mass of undesirable impurities, but biological treatment of these waste products has been more successful than anticipated. There are, however, inhibiting substances, for example, sulphides, cyanides, phenols and toxic metals, which continue to present problems. Further investigations have been made of the application of the activated sludge and percolating systems. These have become in the investigation of bacteria, genus *Thiobacillus*, complicated enough to require the application of computer analysis to the copious data obtained. A realistic approach to the investigation of the polluting effects of various effluents has been provided by an assessment based on the amount of clean water required to dilute them to a concentration such that fish life might reasonably be expected to be supported. Finally it would appear that coke-oven liquor in limited proportions could be treated with sewage on filters. Where sewage works are being rebuilt or extended it may be possible to make more use of this method of disposal in the future.

The possibilities of developing new or improved processes for the production of a fuel suitable for the blast furnace have been further considered. It appeared to be fairly certain that a coke could be made from coals cheaper than those used in conventional carbonization by a continuous multi-stage process involving mechanical forming of the piece, that is to say, by using a briquetting process. The overall economics of such methods appeared, however, to be generally more attractive in areas of the world where good coking coals were in short supply.

The annual report makes reference to other topics that must be of particular interest to the expert. In addition to the aforementioned special report, there is given a notable list of interesting publications released during the year on a wide variety of subjects, including the following: *Future Trends in the Development of the Coking Industry* by the director, Mr. G. W. Lee (Hodsman Memorial Lecture); a report on *The Russian Coking Industry, 1962*; and the scientific papers emanating from the fundamental studies at the Universities of Newcastle and Hull, carried out respectively under the guidance of Prof. W. F. K. Wynne Jones and Dr. J. J. Kipling.

A final word of comment relates to the benefits emerging from the many years of fruitful effort made by the Association on the scientific control of coke manufacture. This has involved the painstaking development of better methods of analysis and testing, and these have now been demonstrated to the industry with the help of a mobile laboratory and the necessary liaison staff. During recent years both the average level and the consistency of coke quality have improved throughout the industry. This is in no small measure due to the adoption of standard methods of sampling and assessment of the quality of coke, and these methods have also made possible the operation of a price structure based on coke quality.

The mobile laboratory has also served as a base for Association teams carrying out investigations at members' plants. This new service to members has strengthened the link between the staff of the Association and that of the industry served. This is an important feature of the Association's activities and has also been shown to be extremely valuable in other research associations supported by the Department of Scientific and Industrial Research. It goes without saying that success of the sort achieved by Mr. Lee and his staff also implies receptivity on the part of the industrial personnel.

RADIATION INJURY

UNDER the title *Physical Factors and Modification of Radiation Injury* the New York Academy of Sciences has published a number of papers and discussions given in New York at the end of 1962*. As such the publication is probably one of the most stimulating and rewarding volumes on radiobiology so far available.

The papers in the first section on "Physical Factors Modifying Response to Radiation" are each a delightful balance between a simple review of the subject and presentation of new experimental data with ideas for fundamental analysis and further thought. The subjects of radiation quality and biological effect; the effect of linear energy transfer (LET) as tested in biological systems from bacteria to mammalian cells *in vitro* and *in vivo*, and in whole animals; the relationship of LET to modification of radiation damage by dose fractionation, anoxia and chemical protectors, show how nearly fundamental radiobiological research comes to solving some major problems of radiotherapy. In one group of papers, however, related to the "Diagnosis, Treatment and Prognosis of Human Radiation Injury from Whole-body Exposure", one is struck by the difficulty of applying radiobiological data directly, and the empirical medical approach of considering each case at the bedside must still be the prescribed course.

Somewhat in contrast to the foregoing, the papers in Part 2, resulting from the conference on "Modification of Radiation Injury by Bone Marrow Transplantation and Chemical Protection", are a mixture of detailed experimental work designed to shed light on one small part of the field, of interest only to the real expert; three or four excellent technical papers grouped together at the end of the volume; and unfortunately, at least one example of an æsthetically unpleasant experimental paper with remote scientific justification on the "Enhanced Survival of Skin Homografts in Mice with a Bacterial Infection".

The volume, with good bibliography, will be essential reading for those concerned with recent developments in radiobiology, and its applications to radiotherapy. It retains some of the overwhelming nature of the meeting itself, but has crystallized the main points of the conferences for easy assimilation.

ELIMINATING DETERGENT FOAM

THE elimination of detergent foam has been a problem of world-wide concern ever since the introduction of synthetic detergents on a large scale after the Second World War. It is still with us, but there are encouraging signs of a solution. The subject is discussed in a short but informative article in *Rohm and Haas Reporter* (Philadelphia, Pa., 22, No. 1, January–February 1964).

Surfactants are commonly classified as either 'soft' or 'hard'; the former are 'biodegradable', readily decomposing in the presence of bacteria in sewage plants, septic tanks and natural waters; the latter are non-biodegradable, resistant to bacterial decomposition. Most synthetic detergents to-day utilize hard surfactants; thus they do not degrade fast enough after fulfilling their cleansing function and their presence is constantly being revealed in rivers, sewage effluents, and so on. It is perhaps commonly assumed that the amount of foam provided by a detergent, for example, in shampoos, washing and dishwashing compounds, is a criterion of the efficiency of its cleaning action; actually the amount of foam has little to do with its cleansing power; it may look good to the housewife but its main function is that of floating out dirt particles, holding them in suspension until they are rinsed away. But it is what happens afterwards to this foam that is the concern of river boards, sewage disposal authorities and public health officials.

The Rohm and Haas Co. claims to be the first firm to offer a non-ionic surfactant for biodegradability by its introduction of 'Surfactant *DN*-65' in the summer of 1963. According to the article: "Now commercially available, the 100 per cent active, nonionic surfactant is supplied as a water-soluble liquid for detergent formulations. Surfactant *DN*-65 is rapidly degradable by the bacteria normally present in waste disposal systems and natural water supplies. The new detergent concentrate is designed to replace the conventional water-soluble octyl and nonyl phenoxy poly-ethoxy ethanol-type surfactants, where biodegradability is required. River

Water DieAway Tests using surface tension measurements as an indicator show Surfactant *DN*-65 to be 95 per cent biodegradable." It is claimed for this product that it is compatible with anionic, cationic, and non-ionic surface-active agents; it is stable, soluble in hydrochloric and phosphoric acids in concentrations up to 5 per cent, and in most common solvents; the foaming, textile-wetting, emulsification properties are said to be excellent and it possesses a hard surface detergency. "It is recommended for use in industrial maintenance formulations, speciality items for home and industrial needs, fabric detergents, metal-cleaning formulations, wax strippers, liquid hand dishwashing detergents, and detergent sanitizers."

Other biodegradable surfactants are being developed in the research laboratories of this firm and they are all geared to the same objective: getting rid of detergent foam.

FURTHER USES OF ELECTRONICALLY SCANNED SONAR IN THE INVESTIGATION OF BEHAVIOUR OF FISH

By Dr. V. G. WELSBY and J. R. DUNN
Department of Electronic and Electrical Engineering, University of Birmingham
AND
C. J. CHAPMAN, D. P. SHARMAN and R. PRIESTLEY
Marine Laboratory, Aberdeen

A PREVIOUS communication[1] described some preliminary trials with a new high-resolution sector-scanning sonar which showed it to have potential usefulness in the investigation of the behaviour of fish, particularly where direct optical observation was impossible. The instrument has recently been used in further examination of the behaviour of fish: (*a*) in large experimental tanks; (*b*) in the vicinity of power station cooling-water intakes.

(*a*) Experiments were carried out on about 100 adult herring (23–29 cm long) in a tank measuring 16 m × 13 m, the depth of water being 1·4 m. The sonar transducer was placed at one end looking down the length of the tank (Fig. 1).

The fish echo-traces on the sonar display screen were photographed with exposures of up to 3 min, thus allowing the moving bright spots to form tracks representing the paths followed by individual fish. A typical result is shown in Figs. 2*a* and 2*b*, taken respectively in light and darkness. The camera film was used, in effect, to carry out a time integration of the movements of the fish. There was a striking difference between the forms of the patterns obtained in daylight and darkness due to changes in the shoaling behaviour of fish. Confirmation of this was obtained when artificial lighting was switched on at night and the 'darkness' pattern immediately reverted to the 'daylight' one.

A further series of experiments was carried out to see how the herring would react to sound stimuli introduced at one end of the tank (as shown in Fig. 1). Figs. 3*a* and 3*b* refer to a typical experiment at night in which a pure tone of 100 c/s was introduced into the tank through an underwater loud-speaker (Type *J*9, Chesapeake Instrument Co.). After an initial quiet period (Fig. 3*a*), the sound was switched on for the duration of the photographic exposure. Fig. 3*b* shows the distribution of fish during this time, and it is clear that the majority of the herring were avoiding the area of the tank in the vicinity of the sound source. The sound was monitored by an underwater hydrophone. Similar reactions to 100 c/s were observed in daylight.

(*b*) The scanner was used to observe fish behaviour in the River Forth in front of the cooling water intakes at Kincardine Power Station. At this site the river is extremely turbid, making photographic observations impossible. The intakes were situated at the end of a pier stretching out 200 yards from the river bank and are positioned at right-angles to the tidal flow. The transducer was mounted 8 ft. above the river bed and directed horizontally down river so that it would scan 30° hori-

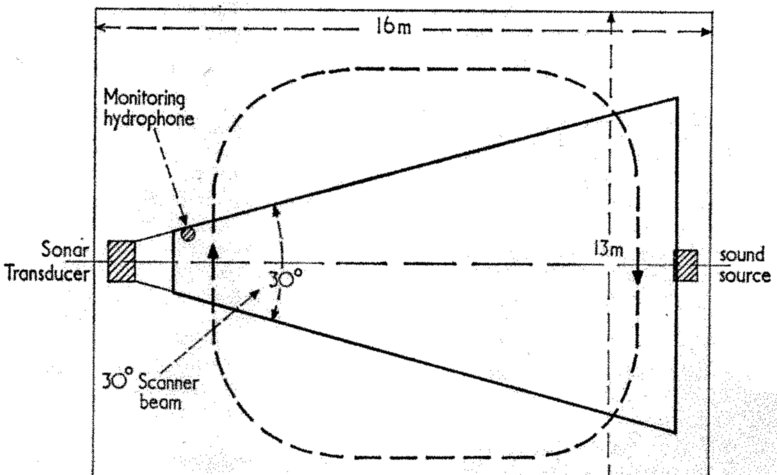

Fig. 1. Diagram of the area of the tank scanned by the sonar set and represented in the photographs of the display screen (heavy line). The circular track of herring shoals in daylight is represented by the broken line

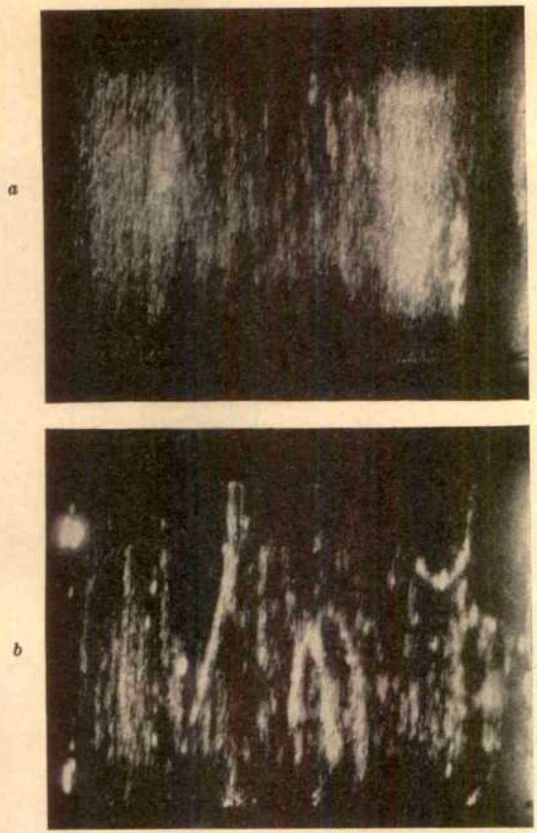

Fig. 2. Time-integrated photographs of display screen showing the distribution of herring: (*a*) in artificial lighting and (*b*) in darkness (3 min exposure)

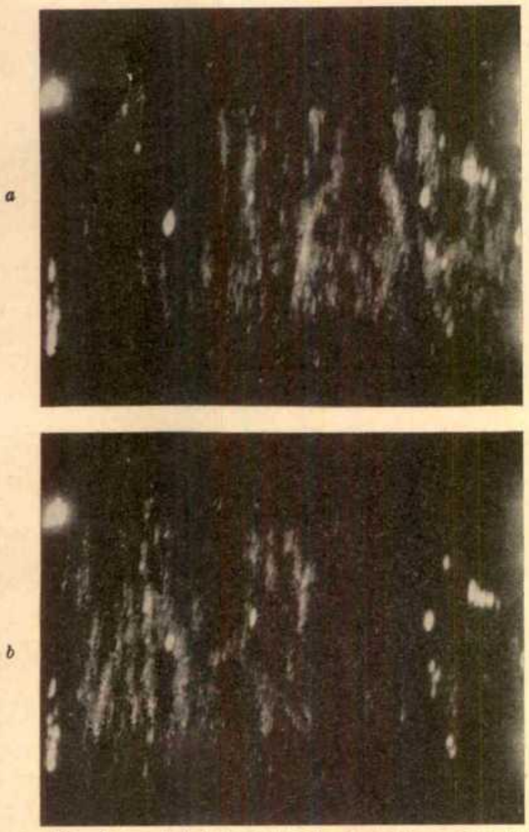

Fig. 3. Time-integrated photographs showing a response to 100-c/s sound: (*a*) before the sound was switched on showing fish near the sound source and (*b*) immediately after switching on the sound showing avoidance of the area in front of the source. (The bright image in the top left-hand corner of the photographs is the monitoring hydrophone; the small bright spots are fixed targets on the bottom of the tank)

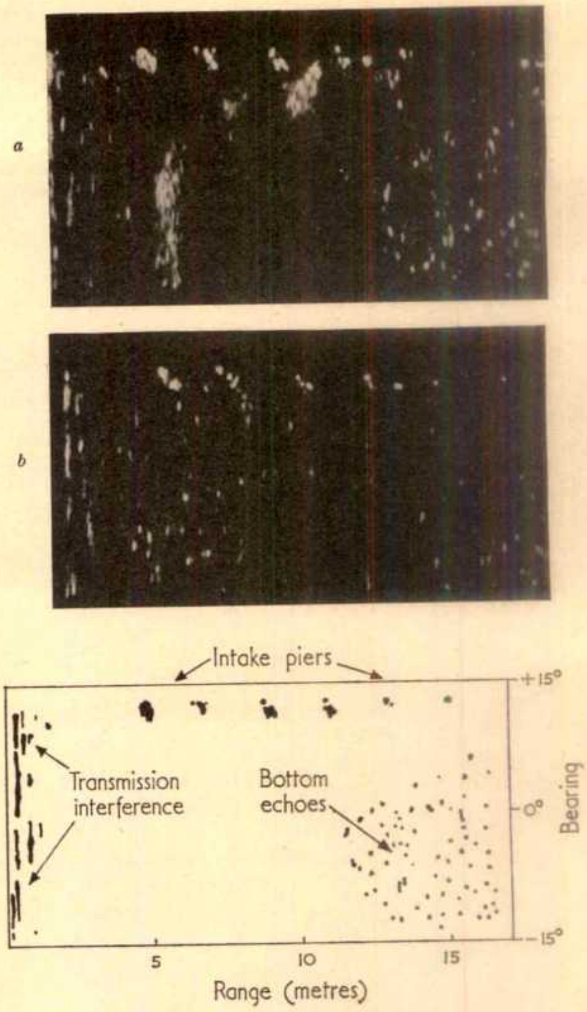

Fig. 4. Two single frames ciné film of the display, taken (*a*) during day, (*b*) at night, show the difference in shoaling behaviour observed off the intakes at Kincardine power station, with an explanatory sketch below

zontally, with a 15° vertical beam, across the intakes. The echo-traces observed on the display screen were recorded on ciné film.

During daylight, tightly packed shoals of fish (probably small clupeids) were observed (Fig. 4*a*). These shoals always moved with the tidal flow, but it was not possible to assess whether the fish were stemming the tide or not. When the ebb-tide had reached its maximum flow (more than 3 knots), air bubbles caused reverberation which completely masked the display.

The scanner was also used in darkness over a similar tidal period to that for the daylight observations. Fish were now observed to be dispersed and were seen as individuals or as small groups (Fig. 4*b*). As with the daylight observations, the fish moved with the tidal flow. The scanner shows convincingly, under these conditions, the complete break-up of the fish shoals at night.

It should be emphasized that in the experimental model described here of the scanning sonar, the scanned sector (Fig. 1) is displayed on a rectangular raster (Figs. 2–4), so that the apparent fish tracks are not geometrically similar to the actual ones. A 'true-motion' display would, however, present no problems and could be provided in future if required. Additional and more detailed experiments are planned, but these observations demonstrate further the usefulness of sector-scanning sonar for fish behaviour research.

HIGH SALINITY IN SEA WATER

Highest Salinity in the World Ocean?

DURING the International Geophysical Year the R.V. *Atlantis*, passing through the Red Sea (Cruise 242), found an anomalously high temperature in the deep water opposite Jeddah. This was reported by Neumann and Densmore[1] in an unpublished manuscript of the Woods Hole Oceanographic Institution. On its way to join the International Indian Ocean Expedition the new R.V. *Atlantis II* carried out a series of hydrographic stations along the length of the Red Sea. Purposely, the ship

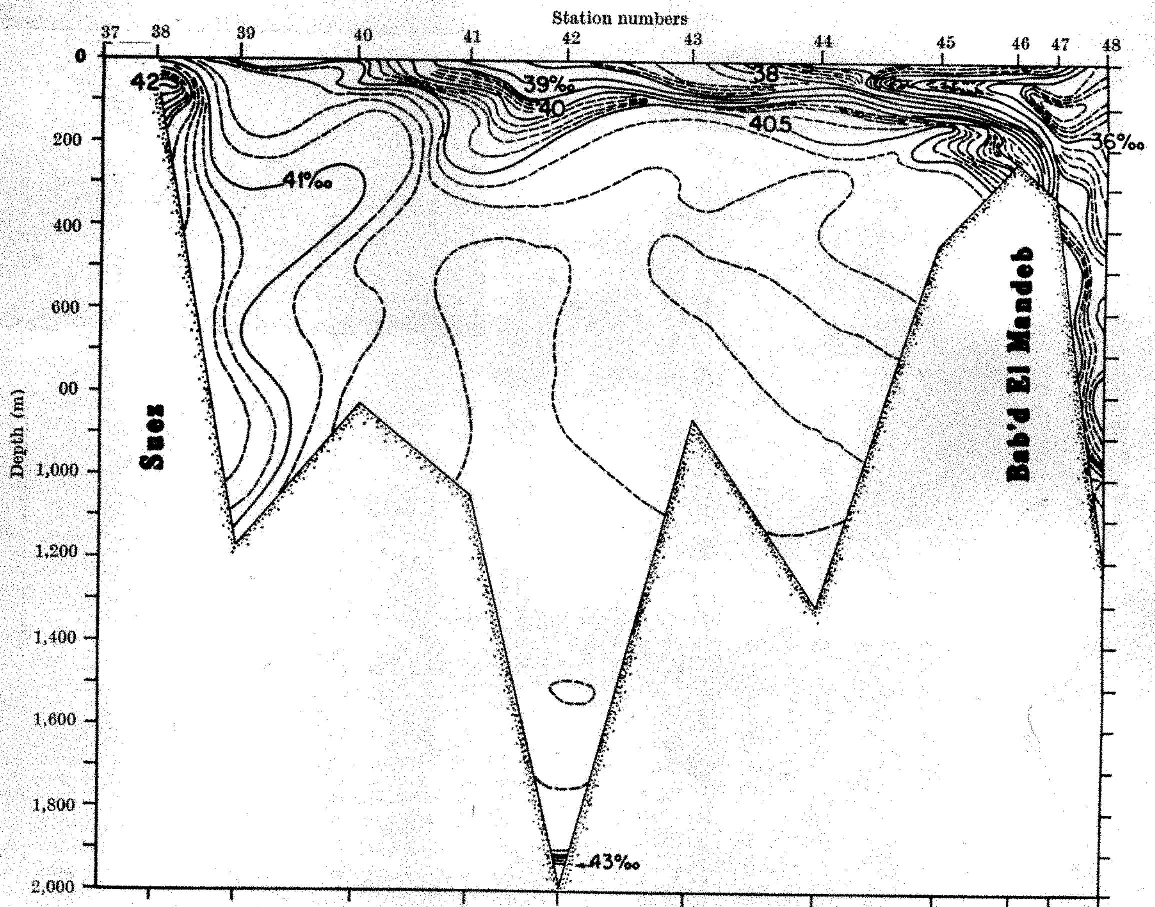

Fig. 1

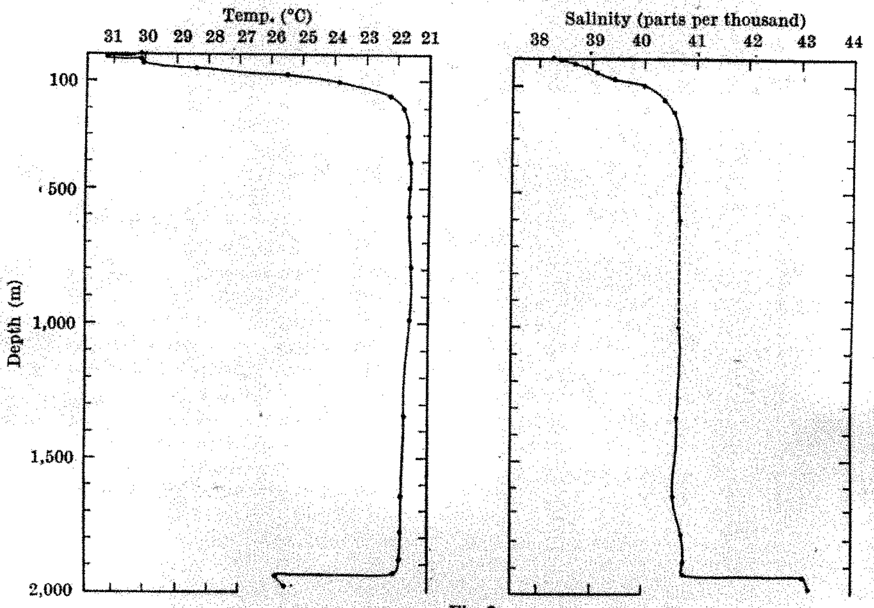

Fig. 2

stopped at the position where Neumann and Densmore[1] found this high temperature. At 21° 21·5′ N., 38° 04·5′ E., Station 42–*Atlantis II*, samples of high-temperature, high-salinity water were obtained close to the bottom.

Fig. 1 gives the profile of salinity distribution from the Gulf of Suez to the Straits of Bab'd El Mandeb as determined from the R.V. *Atlantis II* during July 1963. At Station 42 in the deepest part of the section, 1,931–1,978 m., the water was found to be 25·76°, 3·5° warmer than the rather homothermal water above it. Its salinity was 43·18 parts per thousand, 2·4 parts greater than the surroundings immediately over this band of anomalous water (approximately 50 m thick). Fig. 2 gives the vertical distribution of temperature and salinity for Station 42.

(More recently the British R.R.S. *Discovery* has sampled even deeper depths, 2,400 m, in the neighbouring area and has found clear indications of mixtures of normal Red Sea water and the hot salty water from Station 42.)

Cruise 8 of R.V. *Atlantis II* was sponsored by grant *NSF-GP*821 from the U.S. National Science Foundation.

Anomalous Bottom Water in the Red Sea

WATER below 1,000 m in the Red Sea usually has a potential temperature between 21·5 and 21·6° C and a salinity close to 40·6 parts per thousand. But in a small basin around 21° 15′ N., 38° 05′ E., three research vessels (refs. 1 and 2 and preceding communication) have reported anomalously warm and salty water in the lowest 50 m. In this small basin, the depth of which is almost 2,000 m, the potential temperature reached 25° C and the salinity almost 44 parts per thousand.

A few miles to the south there is a larger basin, the depth of which approaches 2,400 m. A hydrographic station in this basin (21° 07′ N., 38° 10′ E.) was made from R.R.S. *Discovery* on March 1, 1964. In Fig. 1 the potential temperature is plotted in relation to the salinity so as to show that the water below 1,500 m contained the anomalous water much diluted with typical Red Sea deep water.

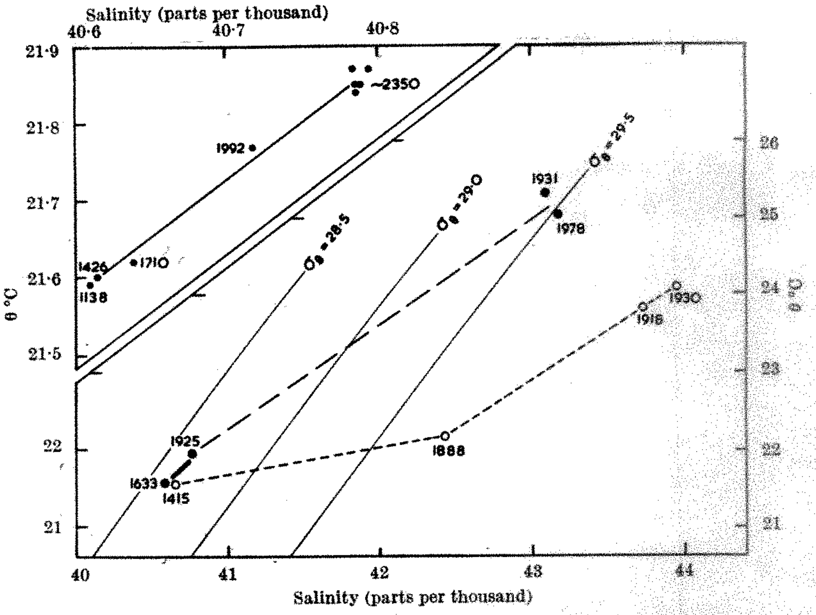

Fig. 1. Potential temperature/salinity diagram for hydrographic stations in the Red Sea. Upper left: ●, *Discovery* 5247; 21° 07′ N., 38° 10′ E.; March 1, 1964; lower right: ○, *Albatross* 254; 21° 10′ N., 38° 09′ E.; May 3, 1948; ●, *Atlantis II* 42; 21° 21′ N., 38° 05′ E.; August 1, 1963; ——, *Discovery* 5247. The figures by the points are depths in metres. The potential density lines are approximate, being extrapolated from Knudsen's formula

The anomalous water is clearly not widely distributed, and its origin is not clear. A plausible explanation is that it forms in a very shallow land-locked basin and is transferred across the sill by wind action, then to descend as a density current on the bottom. This is not inconsistent with Jerlov's[3] report that the anomalous water contains much material in suspension, but it needs to be further examined because of the relatively low oxygen content.

I thank Dr. J. C. Swallow, principal scientist of R.R.S. *Discovery* when this station was done, for permission to quote these observations in advance of publication.

PATTERN OF CELL MIGRATION DURING CORTICAL HISTOGENESIS

By DR. M. BERRY, DR. A. W. ROGERS and PROF. J. T. EAYRS

Department of Anatomy, University of Birmingham, and Institute of Psychiatry, University of London

THE neural elements of the cerebral cortex are derived by mitotic division from a single germinal layer and attain their definitive arrangement through a process of migration from a juxta-ventricular position towards the superficial cortical surface. Since the classical studies of Tilney[1] it has been generally accepted that the cortical laminæ are formed by three successive migratory waves, the first giving rise to the supragranular, the second to the granular and the third to the infragranular layers. Recently, however, Berry and Eayrs[2] were unable to reconcile this concept with the effects of fœtal X-irradiation on cortical structure and postulated that the neuroblasts giving rise to layers V and VI migrated before those destined to form layers IV, III and II. Quantitative comparisons between neurones of normal and irradiated animals, and comparisons between the development of pyramidal cells in the hippocampus and neocortex, supported this hypothesis. It was suggested that more direct evidence might be obtained from an investigation of the behaviour of neuroblasts labelled with tritiated thymidine.

Each of seven groups of fœtal rats, aged 16, 17, 18, 19, 20, 21 and 22 days post-coitus respectively, have accordingly been given a single intra-amniotic injection of tritiated thymidine. Animals were killed 4 h and 2, 4, 6, 8,

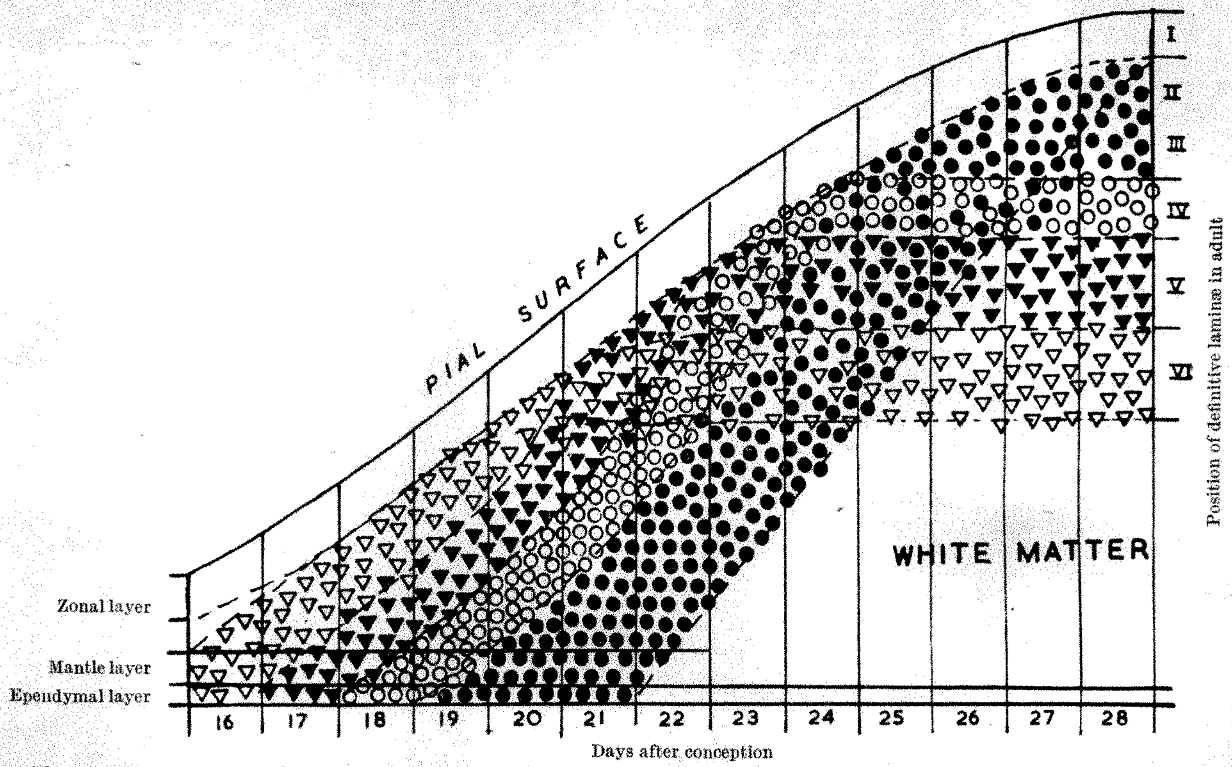

Fig. 1. Schematic representation of the positions occupied by tritium-labelled neuroblasts during successive stages of development. The signals ▽, ▼, ○, ● indicate the ages, shown along the abscissa, at which tritiated thymidine was given. The cells labelled over the period from the 19th to the 21st day of gestation formed the supragranular layers. There was no evidence of lamination into layers II and III by these cells

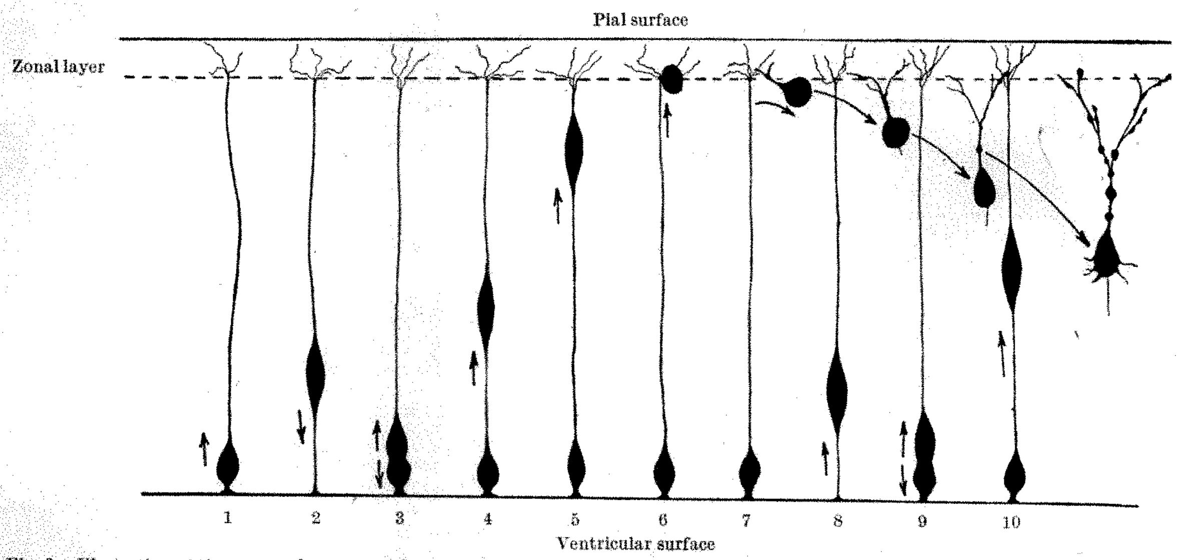

Fig. 2. Illustration of the proposed sequence of events underlying the migration and differentiation of neuroblasts—for explanation see text

10 and 20 days after this injection and autoradiographs of cerebral cortex prepared in a plane passing coronally through the intra-ventricular foramen. Fig. 1, which illustrates diagrammatically the positions occupied by labelled cells at different periods of time after injection, shows that neuroblasts present in the sub-ependymal and mantle layers on the 16th and 17th days of gestation can be traced through successive stages of migration toward the superficial cortex. This position they retain until the 23rd day when cells produced by division on the 18th day near the ventricular surface migrate through them to take up a more superficial position at the pial surface. These cells produced on the 18th day form the granular layer (layer IV) of the adult. The neuroblasts which arise by cell division between the 19th and 21st days migrate through the developing infragranular and granular layers to reach the pial surface about 6 days later, where they differentiate into the supragranular layers II and III. These findings therefore support the hypothesis of Berry and Eayrs[2] and are at the same time consistent with the results of the comparable autoradiographic examinations of Angevine and Sidman[3] using the mouse. In this connexion it is worthy of note that the phylogeny of the cerebral cortex may be closely related to this pattern of histogenesis in so far as the addition of the superficial laminæ, and hence the degree of complexity of the organ, may be attributable to a prolongation of the period during which mitosis may occur in the ependymal layer.

Examination of Nissl, silver and Golgi–Cox preparations in the light of the autoradiographic findings has suggested a possible mechanism by which the migration of neuroblasts takes place. These observations showed that:

(*a*) Ependymal cells, although actively mitotic, remained morphologically unchanged during the developmental period, retaining two processes attached by end feet one to the ventricular wall and the other, much finer, to the pial surface of the cortex. After division, both nucle iappeared to remain within the scanty cytoplasm of the superficially directed process, suggesting that cytoplasmic division did not take place in this region.

(*b*) In regions of the developing cortex which, as shown by autoradiography, contained only migrating cells the perikarya invariably presented a bipolar appearance, the two fine processes coursing radially. The cells contained little cytoplasm except at their two poles and the nucleus was ovoid and darkly staining. The processes, as seen in Golgi–Cox preparations, were indistinguishable from those of the ependymal cells.

(*c*) At later stages of development, two cell types could be identified in Nissl and silver preparations both in the superficial cortex and in those deeper layers in which autoradiographs indicated the presence of some cells that had ceased migration. One had the typical morphology, described above, of a migrating cell; the other possessed a large, pale, spherical nucleus and cytoplasm which was difficult to distinguish from the surrounding matrix. In Golgi–Cox specimens such cells were seen to possess irregularly orientated processes quite distinct from the bipolar processes of the migrating cell.

Although it has not been possible unequivocally to demonstrate a continuous function from a series of static pictures these observations would seem to warrant the hypothesis illustrated in Fig. 2. This proposes that the nuclei of the ependymal cells divide near the ventricular surface of the cortex but that the cytoplasm does not. One of the daughter nuclei remains *in situ*, the other migrating towards the pial surface within the cytoplasm of the superficially attached process of the ependymal cell. In the basal part of the zonal layer cytoplasmic division occurs and the nucleus, with its initially scanty cytoplasm, begins to differentiate independently. During the course of this differentiation the cell is displaced from the pial surface by the subsequent migration and differentiation of succeeding cells.

In this way an anatomical explanation is provided for the orderly way in which cells appear to pass unimpeded through such physical barriers as the dense populations of cells formed by previous migrations and developing fibre tracts.

MECHANISMS OF SENSITIZATION TO X-RAYS OF MAMMALIAN CELLS BY 5-BROMODEOXYURIDINE

By Dr. J. T. LETT, Miss G. PARKINS and Dr. P. ALEXANDER
Chester Beatty Research Institute, Institute of Cancer Research, Royal Cancer Hospital, London, S.W.3
AND
Dr. M. G. ORMEROD
Physics Section, Royal Military College of Science, Shrivenham, Wilts

DJORDJEVIĆ and Szybalski[1] demonstrated that mammalian cells are sensitized to the killing action (defined as loss of ability to divide indefinitely) of X-rays if grown in media containing 5-bromodeoxyuridine (BUDR) under conditions where part of the thymine in DNA is replaced by 5-bromouracil (BU). Szybalski[2] suggested that radiation-induced scission of the main chain of DNA at the phosphate-ester bond was facilitated by the introduction of a bromine atom into the molecule. An alternative mechanism for sensitization that has been envisaged[3] is that BU incorporation renders radiochemical damage sustained by DNA more difficult to repair by post-irradiation metabolic processes. We have attempted to distinguish between these two possibilities: (1) by investigating radiochemical damage in normal and BU-containing DNA; (2) by comparing the degree of sensitization that can be obtained with BUDR in mutants which differ in radiosensitivity because they vary in capacity to undergo post-irradiation repair.

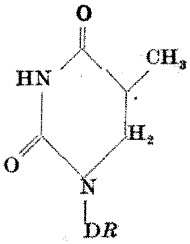
Radiosensitivity of BU-containing DNA

Irradiation of DNA inside cells. E. coli B/r were grown in the sulphonamide-containing medium in which they will incorporate added BU (ref. 4). The extent of incorporation of BU was measured by chromatographic analysis of the nucleotides following enzymatic hydrolysis[5]. Cells were obtained containing DNA in which 49 per cent of the thymine was replaced by BU and which were sensitized by a factor of 3·2 (*Do* reduced from $1 \cdot 3 \times 10^{4}$ to $4 \cdot 0 \times 10^{3}$ rads as a result of BU incorporation) towards aerobic irradiation by 220-kV X-rays in *p*H 7 phosphate buffer. To determine the extent of main-chain scission of DNA these cells were irradiated at 0° C with $1 \cdot 1 \times 10^{5}$ r. of X-rays (at $1 \cdot 1 \times 10^{4}$ r./min), after which they were immediately lysed with dodecylsulphate and their DNA extracted by the Marmur[6] method. After purification the molecular weight of the DNA was determined from measurements of the sedimentation constant by ultraviolet optics and its viscosity in a Couette viscometer extrapolated to zero shear. From these two measurements it is possible to determine the nature of the change in macromolecular structure following irradiation[7]. The only detectable physico-chemical change was a decrease in the average length of the double helices due to the production of 'double breaks' and there was no evidence of cross-linking. The extent of chain scission is measured as a decrease in the average molecular weight, which fell from $10 \cdot 9 \times 10^{6}$ to $6 \cdot 3 \times 10^{6}$ for control cells and from $11 \cdot 3 \times 10^{6}$ to $6 \cdot 5 \times 10^{6}$ for cells with 46 per cent thymine replaced by BU. This experiment indicates that BU does not increase the extent of main-chain scission when the DNA is irradiated *in situ* under conditions where the cells are more radiosensitive.

Irradiation of DNA in isolation. The same conclusion was reached when the DNA was isolated from the cells and then irradiated in dilute solution (0·1 per cent in aerated 0·1 M sodium perchlorate). The extent of main-chain scission measured by the drop in viscosity of the solution was indistinguishable for the control and BU-containing sample (dose to reduce viscosity to one-half being $3 \cdot 5 \times 10^{3}$ r. in both cases). When DNA is irradiated in the dry state, both cross-linking and degradation occur, and the physico-chemical changes are complex and depend very much on environmental factors[8]. Using a number of tests we were unable to detect an effect of the introduction of BU in either cross-linking or degradation following irradiation in the solid state.

Radiation-induced radical formation. While the foregoing experiments appear to eliminate the hypothesis that BU incorporation increases radiation-induced main-chain scission the possibility remains that radiochemical damage at sites other than the phosphate ester bond is enhanced. If BU, when incorporated into DNA, is very much more susceptible to damage than thymine then the resultant overall increase in damage to the DNA might be responsible for sensitization of cells. This view appeared to find support from investigations[9] using electron spin resonance in which it was claimed that the number of radiation-induced radicals which are formed when BU is irradiated at room temperature was nine times that formed in thymine. We were unable to reproduce this result for irradiation either at room temperature or at −196° C (at which temperature the more unstable radical species are trapped) and decided to compare radical formation in normal and 44 per cent bromouracil substituted DNA (BU–DNA) irradiated with cobalt-60 γ-rays (0·5 × 10^6 r./min) under vacuum at −196° C and at room temperature.

The electron spin resonance measurements were made on a conventional X-band spectrometer with a transmission cavity and 105-kc/s modulation. The spectra were plotted as the first derivative of the power absorbed against increase in magnetic field and are shown as such in Fig. 1. Quantitative estimates of free radical concentrations were made by double integration with a second moment balance[10] and comparison with a coal or Mo_2S sub-standard which had been calibrated against DPPH. The number of radicals formed per g DNA as a function of dose are shown in Fig. 2. On irradiation at 77° K the DNA gave an electron spin resonance spectrum which consisted of a single line (Fig. 1). On warming to room temperature, the radicals decayed and the eight line spectrum which has been previously reported[11] became prominent (Fig. 1). This radical is probably formed by the addition of a radiation-produced hydrogen atom to the thymine ring. The changes in the spectrum of DNA on standing at room temperature show that there is more than one radical species present and that this particular thymine-type radical is not the most dominant species formed by radiation, but happens to be the most stable and the most easily observed owing to the spread of the lines. At −196° C before warming to room temperature, it is estimated that the thymine type radical forms less than 10 per cent of the primary radicals formed, but on standing it represents 60 per cent of the total because the other radicals have decayed. There is no foundation for the claim[11] that on irradiation of DNA the predominant radicals formed are those due to addition of hydrogen to the thymine base.



On irradiation at −196° C the BU–DNA gave an electron spin resonance spectrum which was similar to that from DNA (Fig. 1). The radical yield (*G*-value) of BU–DNA was approximately 25 per cent higher than for normal DNA both for irradiation at room temperature and at −196° C (Fig. 2). On warming the sample to room temperature a spectrum slightly different from that of DNA was observed. The major difference was the absence of the eight-line thymine-type spectrum. Since only 44 per cent of the thymine had been replaced by bromouracil it was expected that the thymine-type spectrum would only be reduced by half. Its complete absence suggests that the bromouracil scavenges hydrogen atoms more efficiently than thymine. These results show that the introduction of 44 per cent of BU reduces the average energy required to form a radical in DNA by some 25 per cent. If this increase in radical yield caused a comparable increase in radiochemical damage of the type that results in cell death, the magnitude of such an effect is quite insufficient to explain the increase in cell sensitivities which have been reported. To account for the radiosensitization of cells on a purely radiochemical basis, it would be necessary to postulate that damage to BU had a much greater probability of being lethal than damage to the other bases.

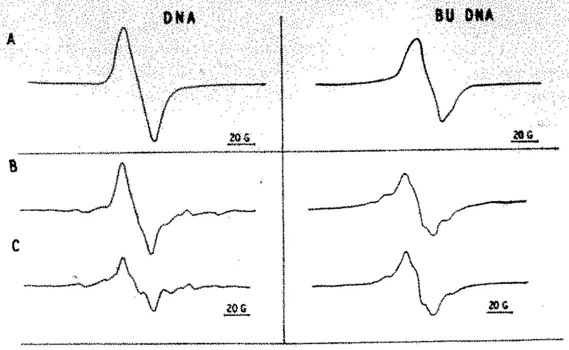


Fig. 1. Electron spin resonance spectra of DNA and DNA in which 44 per cent of the thymine was replaced by 5-bromouracil irradiated at −196° C with 2 × 10^6 rads of cobalt-60 γ-rays *in vacuo*

Radiosensitization of Murine Lymphoma Cells

Mutant strains of the lymphoma cell, *L* 5178 *Y*, which vary in radiosensitivity have been isolated[12]. For this investigation two strains grown in 'simplified' and full medium[13] and referred to as *S*/*S* and *S*/*F* respectively were used. They were both diploid (85–90 per cent of the cells had 40 chromosomes) and had the same DNA content (0·85 × 10^{-11} g/cell), generation time (10·5–11·5 h at 37° C) and cell diameter (8–10μ). The effect of X-rays on suspensions of these cells in tissue-culture medium is shown in Fig. 3. The surviving fraction was estimated by establishing the maximum dilution at which the cells will grow in medium containing 10^5 irradiated feeder cells per

Fig. 3. Survival curves of two strains of lymphoma cells having different BU contents expressed as percentage replacement of thymine (in their DNA) following irradiation with 220-kV X-rays (750 r./min) of an aerated suspension of 10^5 cells/ml. at 37° C

ml. Under these conditions the cloning efficiency from one cell approaches 100 per cent. The survival of the *S/S* cells after irradiation can be enhanced by storage for 12 h at sub-optimal temperature[13]. As had previously been demonstrated for mutants of *E. coli B* (ref. 14), differences in post-irradiation recovery potential are largely responsible for their differences in radiosensitivity. To determine the effect of BUDR on the sensitivity to X-rays of these cells they were grown in media which contained BUDR in the range of 10^{-6} and 10^{-5} M for two and a half divisions. Except at high BUDR concentrations the growth rates of the cells was not affected. Thereafter they were irradiated with 220-kV X-rays, washed and re-suspended in media enriched with thymidine and their survival determined. Depending on the extent of treatment, BUDR rendered up to 70 per cent of the cells non-viable. The average extent of replacement of thymine by BU was determined by chromatographic analysis of the nucleotides of the DNA isolated from the cells[5]. Centrifugation in a cæsium chloride density gradient[15] of native and denatured DNA showed that, except at the higher BUDR concentrations which affected the cellular growth rates, BU substitution occurred in both strands of the DNA in at least 80 per cent of the cells. The survival curves shown in Fig. 3 do not appear to be 'multi-hit' curves in the accepted sense, but for the present we have disregarded this possibility and have expressed radiosensitivity in the conventional way as *Do* (that is, the dose needed to reduce survival by a factor of $1/e$ on the 'linear' portion of the curve). From Fig. 3 it is apparent that the more radio-resistant strain *S/F* is sensitized to a much greater extent than the *S/S* line. When more than 20 per cent of the thymine had been replaced by BU the two strains showed the same radiosensitivity (*Do* ~ 30 r.).

Fig. 4 shows that the two cell lines respond quite differently to the incorporation of BU. The point for *S/S* at 60 per cent incorporation requires qualification, because the survival curves indicate that two cell species are present; 80 per cent of the population show a sensitization of 1·8 while the remainder are only sensitized by a factor of 1·3.

Since the survival of *S/S* can be enhanced by post-irradiation treatments it would appear that the metabolic systems responsible for repair of primary radiochemical damage (probably to DNA) do not operate fully in these cells under normal conditions. The small and progressive increase in radiosensitivity, due to BU incorporation, can be correlated with the greater susceptibility of BU-substituted DNA to undergo radiochemical changes, as shown in the measurements of free radical yield by electron spin resonance. In the *S/F* strain there is a very pronounced sensitization at relatively small BU incorporation. As the BU incorporation is increased beyond 10 per cent the further sensitization occurs much more slowly and resembles the behaviour of the *S/S* line. The sensitization of *S/F* by small amounts of BU can be interpreted as an inhibition of a repair system (probably enzymatic). When this inhibition is complete, further sensitization proceeds in the manner of unprotected DNA, that is, as exhibited by mutant *S/S*. In general, the curve relating cellular radiosensitivity to BU content is made up of two components. One of these may represent the increase in radiosensitivity of DNA and increases slowly and continuously with BU, while the other rapidly reaches a maximum. In the *S/S* line the second of these components is very small and to a first approximation the curve shown for *S/S* in Fig. 4 can be taken to represent the radiochemical component of sensitization. According to this hypothesis the point of inflexion on the composite curve constitutes an approximate measure of the repair capacity of the cell line in question. Erikson and Szybalski's[16] investigation observed this type of relationship for the radiosensitization of human cells with increased incorporation of iodouracil.

BU incorporation could interfere with post-irradiation repair either by inhibiting the complex enzyme system that must be involved or because the radiochemical change which occurs at a BU residue cannot be restituted while that at a thymine residue can. This last mechanism seems unlikely to be the correct one because interference with repair should not reach a limiting value when as

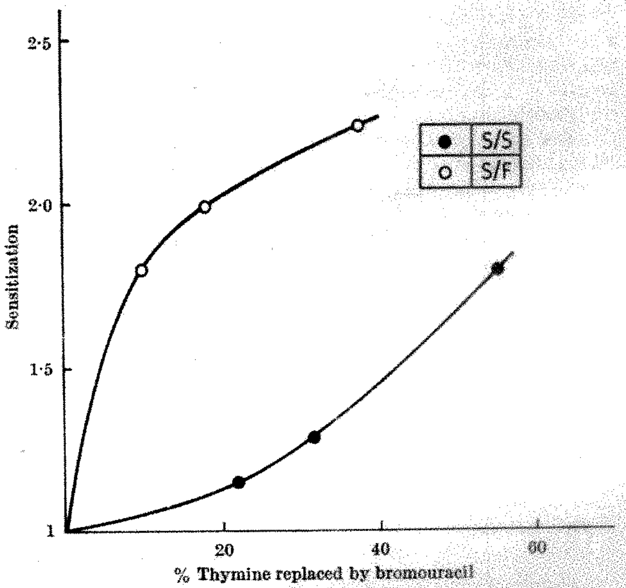

Fig. 4. Relationship between extent of BU incorporation and degree of sensitization to X-rays (expressed as the ratio of the limiting slopes of dose survival curves) for two strains of lymphoma cells

little as 10 per cent of the thymine has been replaced by BU. Blocking of repair enzymes by a process such as substrate inhibition would be expected to show a plateau relationship with BU content. The possibility must be envisaged that other dose-modifying procedures such as the oxygen effect, protection by sulphydryl compounds and sensitization by sulphydryl poisons also work at the level of the repair process. In these cases the protector or sensitizer has to be present during irradiation and it is unlikely that it interferes with the repair reaction directly. However, the repair system may itself be injured by radiation, for example, by damage to membranes or active transport processes. The dose-modifying agents may exert their effect on the radiosensitivity of cells by altering the dose needed to interfere with repair. This would explain why damage to intracellular DNA of cells irradiated under conditions of widely varying radiosensitivity is the same[17], that is, neither protectors nor sensitizers modify the radiochemical damage sustained by the DNA inside the cell. The site of action of the dose-modifying treatments need not therefore be coincident with that of the critical structure. The hypothesis that radiation-induced cell death is determined by two distinct types of primary radiochemical lesions, namely, damage to the critical structure (possibly DNA-nucleoprotein) and the interference with some of the metabolic systems which are responsible for repairing the critical structure, can also explain the great radio-resistance of the micrococcus class of bacteria the DNA of which is very similar in constitution to that of the most radiosensitive Gram-negative cells[17].

We thank Mr. P. Edwards for carrying out the ultracentrifuge measurements. TIME OF SYNTHESIS OF DEOXYRIBONUCLEIC ACID AND PROTEIN IN SPORES OF *B. subtilis*

By Dr. ROBERT E. CANFIELD* and Dr. JEKISIEL SZULMAJSTER

Laboratoire d'Enzymologie du C.N.R.S., Gif-sur-Yvette, France

When trying to understand the factors which govern bacterial spore formation, it is of considerable interest to know the time of synthesis of specific spore macromolecules. The following are the results of experiments designed to obtain information about the time of synthesis of spore DNA and protein in a sporulating strain of *Bacillus subtilis*.

The time of synthesis of spore DNA has been determined by utilizing the technique of 'phosphorus-32 suicide'. This technique is based on the observation that following the disintegration of a critical number of phosphorus-32 atoms in a given molecule of DNA the cell is unable to replicate[1,2]. Thus, measurement of the changes in the number of survivors, in a culture exposed to high doses of $^{32}PO_4^{\equiv}$ during growth, may be taken as evidence for the relative specific activity of phosphorus-32 in the DNA. The time of synthesis of spore DNA was inferred from the relative specific activity of the phosphorus-32 in the DNA of the different spore samples derived from cultures of *B. subtilis* incubated in the presence of a high specific activity of $^{32}PO_4^{\equiv}$ during different phases of their growth-cycle.

Young and Fitz-James[3], using a different technique, have shown that the spore of *B. cereus* receives a part of its parent bacterial DNA during the process of spore formation, and the results reported here are in general agreement with this earlier work.

The time of synthesis of the spore proteins was determined by isotopic labelling with ^{14}C-amino-acids.

DNA synthesis. The general conditions for growth and sporulation of *B. subtilis*, Marburg (wild type), have been described[4,5]. In the experiments reported here a 25-ml. aliquot of an exponentially growing culture was inoculated with carrier-free phosphorus-32 when the $O.D._{650}$ of the culture was approximately 0·3. The Bacto-peptone growth media used contained 22 μg of phosphorus per ml. and the final specific activity was approximately 60 mc./mg phosphorus. Serial aliquots of this high specific activity culture were removed at different time-intervals and transferred to smaller flasks that contained sufficient non-radioactive phosphate buffer to reduce the specific activity of the media 20–40-fold. A separate examination of incorporation of phosphate under these conditions revealed that more than 80 per cent of the phosphate in the medium was incorporated into the bacteria before T_0. (The time of the end of exponential growth has been chosen as an arbitrary time-reference and is designated T_0. The designations T_1, T_2, etc., represent the number of hours after the cessation of exponential growth.) All the cultures were incubated until T_{22}, at which time each flask contained free spores. However, each flask represented a different time-period during which the spore DNA could have been synthesized from the suicide-producing high specific activity pool of $^{32}PO_4^{\equiv}$. At the termination of the experiment, T_{22}, each sample was heated at 80° for 10 min to kill any vegetative cells, and aliquots of the spores were frozen at $-20°$. The number of surviving spores was quantitated at different times thereafter by counting the number of colonies produced when serial dilutions were plated on agar.

When the logarithm of the number of survivors is plotted against $(1 - e^{-\lambda t})$, where λ equals the fractional decay of phosphorus-32 atoms a day, a series of straight lines is produced, and the relative slopes of these lines are, in theory, proportional to the specific activity of phosphorus-

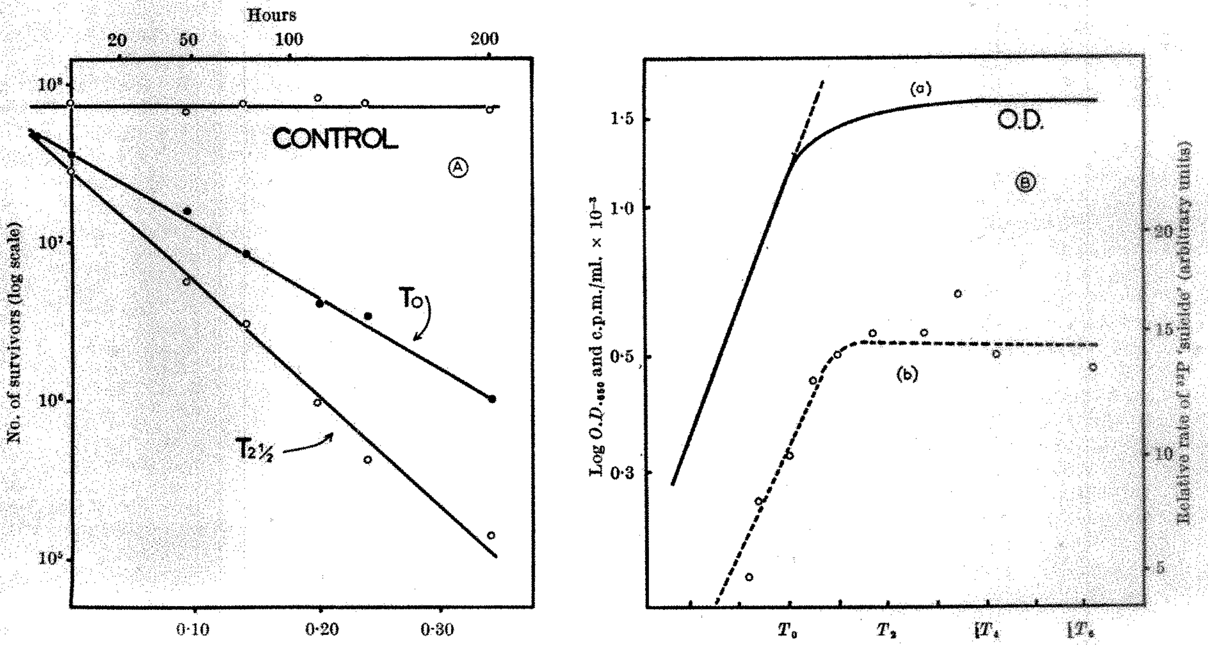

Fig. 1. Inactivation of spores due to disintegration of phosphorus-32. (*A*) Three representative 'suicide' curves depict the number of spores surviving at various times after the completion of the experiment. The samples represented by the two lower curves (T_0 and $T_{2\cdot5}$) were grown in a high specific radioactive medium until T_0 and $T_{2\cdot5}$, respectively, at which times the $^{32}PO_4$ was diluted with non-radioactive phosphate buffer. The control sample contained no radioactivity. (*B*) The relative values of the slopes of all the spore suicide curves (plotted as shown in 1*A*) are represented (curve *b*) versus the time when the high specific activity media were diluted with phosphate buffer. *a*, Growth is indicated by optical density measurements

32 in the DNA of the different samples[1,2]. Some representative spore phosphorus-32 'suicide' curves are shown in Fig. 1*A*.

The relative slopes of all the spore 'suicide' curves are plotted in Fig. 1*B*. Each point on curve *b* relates the rate of spore 'suicide' (ordinate) to the time at which the specific activity of the $^{32}PO_4^{\equiv}$ in the media was diluted (abscissa). It appears that reduction of the specific activity of the phosphate at various times after T_2 does not alter the rate of spore 'suicide', and this is interpreted as evidence that the synthesis of the spore DNA is completed before T_2. The similarity in the shape of the bacterial growth curve (*a*) and the phosphorus-32 'suicide' curve (*b*) suggests that the spore DNA was synthesized as a part of the DNA complement of the last generation of bacteria. As noted earlier, this probability has been suggested by Young and Fitz-James[3] for the spore DNA synthesis of *B. cereus*.

The first spore counts were made 22 h after the termination of exponential growth. Since the results shown in curve *b* of Fig. 1*B* suggest that the spore DNA was synthesized between T_0 and T_2, the 'suicide' curves have been extrapolated to this time, and when this is done, the average yield of the spores is 70–80 per cent of the control value. In a separate control experiment it was found that the phosphate buffer, used to dilute the radioactivity, also slightly inhibited the final yield of spores.

Protein synthesis. The existence of a protein turnover during sporulation of *B. mycoides* and *B. thuringiensis* has been shown by Foster and Perry[6] and Monro[7], respectively. Similar results have been obtained in our earlier investigations on *B. subtilis*[8]. It was suggested that this high turnover in the *Sp*⁺ strains is concerned with the synthesis of the specific spore proteins. The present experiments were designed to determine the time and relative rate of this spore protein synthesis.

Bacteria were grown in Difco-peptone broth in the presence of a mixture of ^{14}C-lysine, ^{14}C-phenylalanine, ^{14}C-proline and ^{35}S-methionine. A parallel culture contained comparable quantities of non-radioactive amino-acids. At various intervals of time, equal aliquots were removed from both cultures and centrifuged at 37°.

The radioactive bacteria were suspended in the non-radioactive supernatant and all the samples were incubated for 48 h. Spores were isolated by the method of Sacks and Alderton utilizing a two-phase system of polyethylene glycol and water[9]. The radioactivity of a measured aliquot of the spore suspension was determined by filtering and washing the spores on 'Millipore' filters which were then mounted on planchets. The number of spores was determined in aliquots heated at 80° for 10 min by plating dilutions on agar.

The results, illustrated in Fig. 2, demonstrate that the longer the bacteria remain in the presence of labelled amino-acids, the higher the ultimate radioactivity of the free spores. However, it is interesting to note that there is an apparent plateau between T_2 and T_5 when transfer of the bacteria does not change the ultimate radioactivity

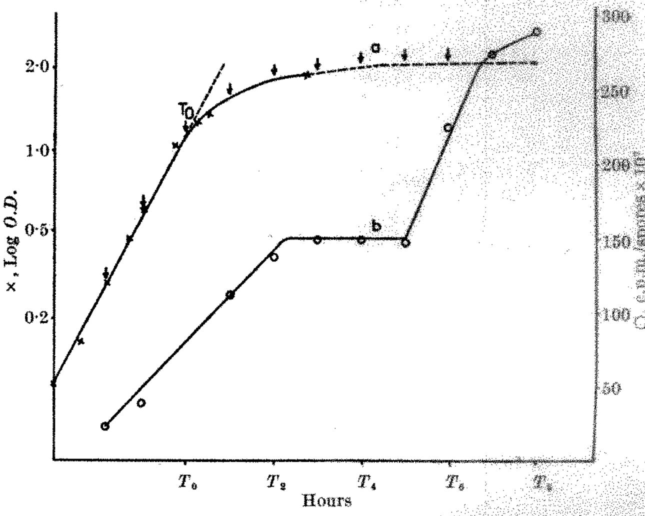

Fig. 2. Synthesis of specific spore protein. Curve *a* is the bacterial growth curve, and the arrows indicate the times at which cultures were transferred to non-radioactive media. Curve *b* (open circles) relates the specific radioactivity of the isolated spores on the ordinate to the time the culture was transferred to non-radioactive media on the abscissa

of the spores. Estimation of the total radioactivity transferred during this time reveals that a relatively constant 5 per cent of the radioactivity in the bacteria at the time of transfer appears later in the free spores. The percentage increases abruptly after T_5 to about 25–30 per cent.

Our interpretation of these results is that the synthesis of most of the specific spore structural protein begins at T_5. Between T_2 and T_5 there is active protein turnover that may involve enzymes necessary for the process of sporulation, but apparently little, if any, specific structural spore protein is made. The 5 per cent of the radioactivity found in the bacteria during this period that does make its way to the free spore may do so by several routes. Probably some is transferred with the DNA as nucleoprotein, while degradation of bacterial protein into the amino-acid pool may provide another route. Very active synthesis of spore protein begins at T_5 and this is consistent with the relatively high rate of amino-acid incorporation that has been noted during this period[8].

When protein synthesis is inhibited at T_5 by the addition of chloramphenicol, the majority of the bacterial population continue to develop heat resistance and to synthesize dipicolinic acid, but the organisms do not achieve the appearance of mature spores[5]. It appears, therefore, that the enzymes involved in the synthesis of dipicolinic acid are formed before T_5 and that the addition of chloramphenicol after this time inhibits the synthesis of protein essential for the morphological and biochemical identity of a complete spore.

DEOXYRIBONUCLEIC ACID BASE COMPOSITION IN CERTAIN BACTERIA AND THEIR MUTANTS WITH IMPAIRED RESPIRATION

By G. G. GAUSE, N. P. LOSHKAREVA, PROF. I. B. ZBARSKY and PROF. G. F. GAUSE

Institute of Animal Morphology, Academy of Sciences, and Institute of New Antibiotics,
Academy of Medical Sciences, Moscow, U.S.S.R.

THE possibility of experimental induction of bacterial mutants with detectable variations in DNA base composition has so far been little investigated. Spirin and Belozersky[1] observed considerable alterations in DNA base composition in some experimentally produced forms of colon bacteria as compared with original strains. Weed[2], examining the action of copper on *Bacillus subtilis*, observed the formation of mutants with the increased guanine–cytosine (GC) content of DNA. Recently, a number of mutants with impaired respiration and altered biochemical characteristics were induced by one of us in various groups of bacteria: *Staphylococcus aureus*[3], *Staphylococcus afermentans*[4], *Bacterium paracoli*[5] and *Bacillus subtilis*[6]. These mutants revealed increased sensitivity to inhibitors selectively suppressing DNA synthesis by cross-linking deoxyguanilic nucleotides. In this connexion the investigation of the GC content in DNA of these mutants was of considerable interest.

Three methods were used in the examination of DNA base composition. First, base composition was determined by the usual chromatographic procedure[1]. Secondly, content of GC was calculated from the melting temperature of isolated and purified samples of native DNA. Thirdly, content of GC was estimated on the basis of extinction ratio at 260 and 280 mμ, *p*H 3 (ref. 7).

It was observed that cells of most mutants were very resistant to different methods of disruption. Therefore, to isolate undegraded DNA they were converted to spheroplasts by the technique of Lederberg[8]. DNA was extracted by phenol from spheroplasts lysed by the addition of sodium dodecyl sulphate and purified according to Marmur's procedure[9]. The melting temperature (T_m) was determined using saline–citrate (0·15 M sodium chloride plus 0·015 M sodium citrate) as a solvent. The T_m for species with high GC content was obtained at a lower ionic strength solvent and corrected to that for saline citrate.

One can see in mutants of *S. aureus UV*-2, *UV*-15 and *UV*-16 a very considerable increase in GC content (69–70 per cent) as compared with that of the parent strain 209 (GC content 32 per cent). Base ratios of mutant 52–1, induced in *B. paracoli*, and of mutants of *B. subtilis*, are also shifted in the same direction (Table 1).

Table 1. DNA Base Composition in some Bacteria and their Mutants as estimated by Chromatographic Procedure

Strains	Molar (%) *G*	*A*	*C*	*T*	$\frac{G+C}{A+T}$	%GC
S. aureus 209	16·5	33·6	15·9	34·0	0·48	32·4
Mutant *UV*-2	35·8	14·4	35·2	14·6	2·45	71·0
Mutant *UV*-15	34·3	15·4	34·9	15·4	2·25	69·2
Mutant *UV*-16	35·4	14·5	35·5	14·6	2·44	70·9
S. afermentans 7503	36·9	12·8	37·4	12·9	2·88	74·3
Mutant 44	36·4	13·6	36·4	13·6	2·68	72·8
Mutant 22	34·9	15·0	35·1	15·0	2·34	70·0
B. paracoli	28·7	21·1	29·1	21·1	1·37	57·8
Mutant 52–1	37·8	12·4	37·6	12·2	3·06	75·4
B. subtilis 168	20·7	29·0	21·3	29·0	0·73	42·0
Mutant *MK*-9	32·4	17·9	31·6	18·8	1·77	64·0
Mutant *MK*-12	31·5	18·2	31·5	18·8	1·70	62·9
Mutant *SC*-22	32·5	17·4	32·6	17·5	1·87	65·1

In the case of *B. subtilis*, mutants *MK*-9 and *MK*-12 were induced by 5-fluorouracil[6], and mutant *SC*-22 was obtained from Dr. Weed, who produced it by copper treatment. All three mutants reveal similar GC content of DNA (63–65 per cent), while the GC content of the parental DNA attains 42 per cent. Mutants of *S. afermentans* 22 and 44 do not show any further increase in GC content. This is probably due to the fact that GC content in DNA of original strain is extremely high (74·3 per cent).

Data on GC content calculated from melting temperature and extinction ratio at *p*H 3 confirm the results obtained by chromatography (Table 2). Considerable discrepancies are observed only with the parental strain of *B. paracoli*.

Table 2 contains additional information concerning mutants of *B. paracoli Bu*-12, induced by bromouracil, and *Cu*-15, induced by copper treatment. These two mutants form small colonies; but they reveal neither any defects in respiration nor increased sensitivity to inhibitors affecting DNA[10]. They also do not reveal any

Table 2. GC CONTENT IN DNA OF SOME BACTERIA AND THEIR MUTANTS AS DETERMINED FROM THE MELTING TEMPERATURE AND EXTINCTION RATIO AT 260 AND 280 mμ, pH 3

Strains	T_m	%GC	$\frac{E_{260}}{E_{280}}$	%GC
S. aureus 209	82·9	33·2	1·579	33
Mutant *UV*-2	98·1	70·2	1·092	71

alteration in GC content of DNA as compared with parent strain.

Analysis of DNA melting profiles of all the bacteria examined shows that DNA preparations are fairly homogeneous and contain only one component. It is essential that the width of the melting intervals is the same for the parent culture and for mutants obtained from it. One may therefore conclude that the increase in GC content of DNA as observed in mutants is not accompanied by any significant change in its compositional heterogeneity.

The data obtained clearly indicate that in various groups of micro-organisms, namely, in cocci, Gram-negative bacteria and Gram-positive bacilli, mutants can be induced which reveal large increase in GC content of DNA. These fundamental changes in DNA base composition are accompanied by deficient respiration, increased sensitivity to inhibitors affecting DNA synthesis, as well as by some profound alterations in the variety of enzymatic systems[11].

These unusual mutants were induced by ultra-violet irradiation and by 5-fluorouracil, which can specifically inhibit replication of DNA. After ultra-violet irradiation or thymine starvation, caused by the action of 5-fluorouracil, multiple lesions may form in the DNA molecules as a result of thymine dimer formation[12], or chain breaks[13]. One might suggest that some cells in the bacterial population can 'heal' such lesions during subsequent replication of DNA. During this 'healing process' deoxyguanilic and deoxycytidilic residues might be used preferentially for repair of the lesions and that might cause the observed increase in GC content in DNA of mutants.

This suggestion is supported by the recent results obtained by Bollum and Setlow[14], who reported that replication of ultra-violet-irradiated DNA *in vitro* results in the increased incorporation of deoxyguanilic acid in the newly formed molecules of DNA as well as by experiments of Pettijohn and Hanawalt[15], indicating the possibility of DNA partial replication after ultra-violet irradiation of cells.

We thank Yu. V. Dudnik and T. V. Kirssanova for their assistance.

SELECTIVE ALTERATIONS OF MAMMALIAN MESSENGER-RNA SYNTHESIS: EVIDENCE FOR DIFFERENTIAL ACTION OF HORMONES ON GENE TRANSCRIPTION

By DR. CHEV KIDSON and DR. K. S. KIRBY

Chester Beatty Research Institute, Institute of Cancer Research: Royal Cancer Hospital, Fulham Road, London, S.W.3

CONSIDERABLE experimental evidence indicates the presence in mammalian tissues of rapidly synthesized RNA (refs. 1–5). This RNA has many of the properties of messenger-RNA (*m*RNA), such as rapid turnover and heterogeneity of size, and its synthesis is inhibited by actinomycin; template activity has been demonstrated in the case of this fraction from rat liver in an *E. coli* system which incorporates amino-acids into proteins[6]. While some workers have suggested that rapidly labelled RNA is synthesized and utilized only in the nucleus[4,7], other recent evidence strongly suggests that transfer of this RNA to the cytoplasm does occur[8,9], as would be expected for messenger-RNA which directed cytoplasmic protein synthesis. It is not known, however, to what extent protein synthesis in mammalian cells is dependent on rapidly synthesized RNA as opposed to *m*RNA with slower turnover and perhaps greater stability; it is also not known whether all rapidly synthesized RNA subserves specific messenger functions. Similarly, there is as yet insufficient data to permit extensive direct analogies with bacterial constitutive, inducible and repressible enzyme syntheses, and with present concepts of regulation of microbial gene transcription[10].

Several lines of evidence suggest that the rate of synthesis of various RNA fractions in mammalian cells may be altered under appropriate conditions, notably endocrine ablation and hormone substitution. Thus, Telfer[11] reported increased uterine RNA synthesis following the administration of œstradiol to ovariectomized rats. Butler and Schade[12] observed a decrease in ventral prostate RNA content in male rats following castration or stilbœstrol administration, while Kochakian and Harrison[13] found that androgens restored to normal the low RNA content of kidney, prostate and seminal vesicle in castrated mice. A single dose of cortisone acetate in intact rats results in increased incorporation of ^{32}P and ^{14}C-glycine into nuclear, microsomal and soluble RNA of rat liver[14]. Many of these and other reports relate to some hours or even days after the relevant treatment and indicate a gradual increase in total cellular RNA after the administration of different hormones.

Hormones have been implicated in the regulation of protein synthesis. Insulin[15], growth hormone[16], cortisone[17], œstrogens[18], androgens[19] and thyroid hormones[20] have all been shown to stimulate incorporation of amino-acids into proteins under specified conditions. However, such is not universally true: Manchester, Randle and Young[21] found enhanced incorporation of glycine into protein of diaphragms from adrenalectomized rats, and diminished incorporation of glycine after pre-treatment with hydrocortisone; Korner[22] reported increased incorporation of leucine into protein by rat liver microsomes following adrenalectomy but decreased leucine incorporation some weeks after adrenalectomy.

Induction of specific enzyme synthesis by hormones has been investigated in certain cases; the induction of tryptophan pyrrolase in rat liver by cortisone provides perhaps the best example. Feigelson *et al.*[17] have shown that cortisone acetate causes a net increase in the number of enzyme molecules and that increased synthesis reaches a maximum 4 h after a single dose of the hormone, coincident with the maximal increase in RNA synthesis[14]. Actinomycin[23] inhibits the cortisone-induced synthesis of tryptophan pyrrolase and also of certain hepatic gluconeogenic enzymes[24]. These investigations have led to the inference that the induction of enzyme synthesis by cortisone is regulated at the level of DNA transcription into messenger-RNA.

This conclusion gains some support from a number of recent reports which suggest that insulin[25], growth hormone[16], thyroid hormones[26], androgens[27] and œstrogens[28] as well as cortisone[29] may be involved in the regulation of *m*RNA synthesis, as judged by their effects on the amounts of rapidly labelled RNA in various tissues. Karlson's observations[30] on the effects of ecdysone on RNA synthesis in *Chironomous tentaris* larvæ suggest that this aspect of hormone action is not limited to mammalian systems.

Any attempt to elucidate the molecular site of action of hormones on RNA synthesis must necessarily be directed towards distinguishing between immediate and subsequent events. It is evident already that increased synthesis of nuclear and cytoplasmic RNA accompanies the increase in protein synthesis directed by hormones and that these changes appear to parallel the rate of synthesis of specific induced enzymes. However, these are relatively slow processes and do not necessarily give any indication of the primary site of hormone action. The fact that many hormones increase the synthesis of rapidly labelled RNA indicates that a preliminary step is stimulation of *m*RNA synthesis, but so far the available data suggest that this increase may be a general one, as shown, for example, by the sucrose gradient patterns of rapidly labelled rat liver RNA after the administration of hydrocortisone[29]. These investigations do not distinguish, therefore, among actions on the RNA-precursor pool, activation of RN polymerase and direction of DNA transcription.

We have approached the question of primary action of hormones by analysing their effects on the synthesis of rapidly labelled RNA in rat liver during short time-periods in a system which permits comparative fractionation of this RNA. The term messenger-RNA (*m*RNA) is applied here for convenience to the whole of the rapidly labelled RNA which is extracted with DNA by the 4-aminosalicylate/phenol method[5], although it is not yet certain that all this RNA directs specific polypeptide synthesis. Available fractionation methods such as sucrose gradient centrifugation and chromatography on methylated albumin kieselguhr columns are useful in characterizing *m*RNA but permit only a limited degree of fractionation. We have found that under standardized conditions of *m*RNA preparation countercurrent distribution (CCD) gives the greatest reproducibility of available fractionation techniques. CCD has the added advantage of permitting a high degree of fractionation by the use of a large number of transfers and by varying the solvent system. We have previously applied CCD to the fractionation of *m*RNA from a variety of mammalian tissues[31] and to the demonstration of progressive alteration of *m*RNA synthesis during the growth of a mouse hepatoma[32]. In the present investigations, CCD has been used to demonstrate selective alteration of *m*RNA synthesis in rat liver and the results suggest differential effects of hormones at the level of DNA transcription.

Adult male and female August rats were maintained on a standard high (20 per cent) protein diet, and after removal and extraction of the liver the *m*RNA was isolated and gave reproducible patterns on CCD. Preparations of *m*RNA were made in all cases after a 20-min pulse of 200 μc. of ^{3}H-orotic acid, the pulse-time being assessed from the time of intraperitoneal injection of the label to freezing of the livers in liquid nitrogen. Each preparation was made from the pooled livers of two rats. After extracting ribosomal and soluble RNA with naphthalene-1,5-disulphonate/phenol/8-hydroxyquinoline *m*RNA was extracted together with DNA from the insoluble interfacial material with 4-aminosalicylate/phenol/8-hydroxyquinoline as previously described[5]. By this procedure the rapidly labelled RNA can be quantitatively extracted[31], thus permitting comparative fractionation of preparations made from animals receiving different treatments prior to pulse-labelling.

The *m*RNAs in the DNA/RNA preparations have been characterized by sucrose density gradient centrifugation[5] and fractionated by CCD[31]. Any degradation, which does rarely occur due to nuclease action, can be readily detected by both these methods[31]. Solvent systems for CCD were similar to those developed for ribosomal RNA[33] except that trilithium citrate was substituted for tripotassium citrate in the aqueous phase, as used for CCD of DNA[34]. A standard solvent system was utilized in the present investigations containing the following proportions: organic mixture 28 vols., amine solution 12 vols., 0·033 M trilithium citrate 12·5 vols., and water 39·5 vols. This system was designated as solvent system 150/12·5 referable to the number of volumes of trilithium citrate used. 2 mg of interfacial DNA/RNA were distributed in this solvent system (3 ml. each phase) over 100 transfers. The material was first dissolved in 3 ml. of each phase of a 150/2 system and distributed by transferring through a gradient of increasing lithium concentration (2 tubes) into the 150/12·5 system. After 100 transfers, 1 ml. of ethanol was added to the contents of each tube to give one phase and radioactivity measured in 2 ml. aliquots (10 ml. scintillation mixture) by liquid scintillation spectrometry. Quenching by the solvents was of the order of 5 per cent and was the same for all fractions. A full discussion of CCD of *m*RNA has been recorded elsewhere[31].

Initial experiments examined the effects of starvation on the pattern of rat liver *m*RNA synthesis. Male or female rats were starved for periods up to 24 h following at least 2 weeks on the 20 per cent protein diet; some animals, after a period of starvation, were re-fed on the high protein diet. Starvation produced a marked increase in the amount of *m*RNA per unit DNA, and CCD fractionation showed considerable alteration of *m*RNA pattern (Fig. 1). Some groups of *m*RNA appeared to be affected more than others. The CCD pattern of *m*RNA prepared from rats starved for 24 h, then re-fed for 40 h on the control diet, showed virtual return to that of the control *m*RNA preparation, indicating the reversible nature of the changes induced by starvation.

The effects of hydrocortisone were examined over short time-periods to obtain some indication of the initial actions of this hormone on *m*RNA synthesis. Intact male or female rats were given a single large dose (5–10 mg) of hydrocortisone succinate by intraperitoneal injection (I.P.I), followed after varying time-periods (5–60 min) by an ^{3}H-orotic acid pulse for 20 min. Striking effects were observed on the resulting *m*RNA CCD profiles (Fig. 2). Even in the shortest time of 5 min before injecting orotic acid, hydrocortisone showed a selective action, increasing some and decreasing other *m*RNA fractions. The peak appearing about tube 18 after 5 min was reduced at longer times after hydrocortisone treatment, but otherwise the time-course showed a continued increase in the broad peak

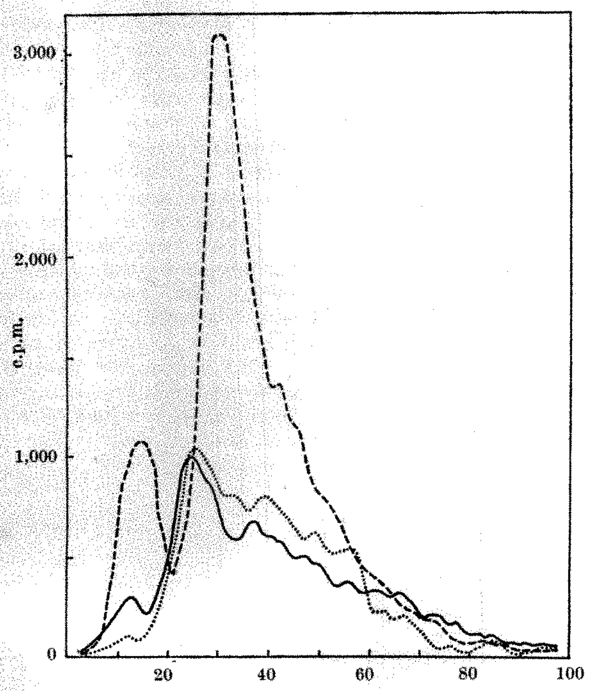

Fig. 1. CCD of rat liver *m*RNA prepared after starvation and re-feeding. 100 transfers in solvent system 150/12·5. ——, control (*m*RNA from rat liver: 20 per cent protein diet); – – –, *m*RNA from liver of rats starved 24 h; . . . . ., *m*RNA from liver of rats starved 24 h, then re-fed on control diet for 40 h

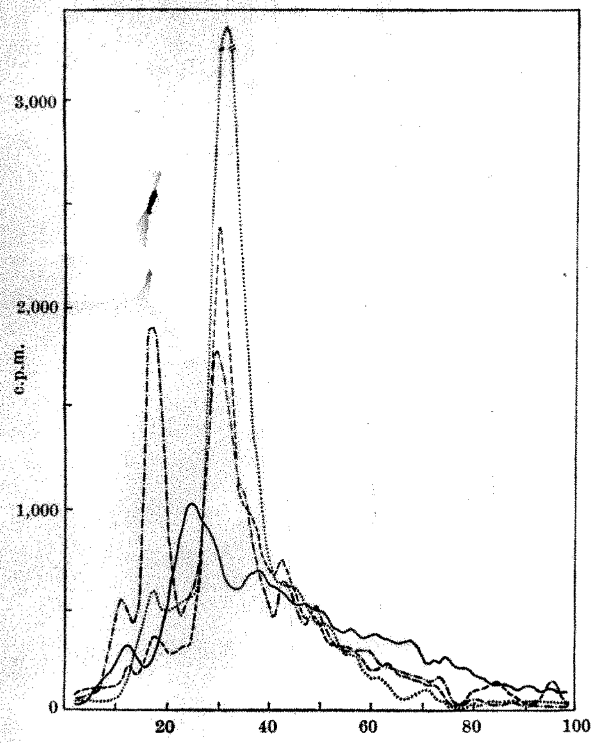

Fig. 2. Effects of hydrocortisone succinate (5 mg/rat) on *m*RNA patterns in rat liver. CCD in solvent system 150/12·5 over 100 transfers. ——, Control (*m*RNA from rat liver: 20 per cent protein diet); —·—·—, *m*RNA from livers of rats receiving I.P.I. hydrocortisone 5 min before pulsing with ^{3}H-orotic acid; – – –, *m*RNA from livers of rats receiving I.P.I. hydrocortisone 15 min before pulsing with ^{3}H-orotic acid; . . . . ., *m*RNA from livers of rats receiving I.P.I. hydrocortisone 30 min before pulsing with ^{3}H-orotic acid

in tubes 25–40. It should be noted that this latter peak is of itself heterogeneous and also that, coincident with the increase in this group of *m*RNAs, other fractions were decreased at all time-periods examined. CCD patterns had returned to normal when examined 24 h after hydrocortisone injection. Whereas these highly selective effects were observed by CCD fractionation, sucrose gradient centrifugation was not sensitive enough as a fractionation technique to show them, and by this latter method we have observed only an apparent general increase in *m*RNA similar to that reported by Kenney and Kull[29].

The effects of insulin on *m*RNA synthesis showed interesting variation with time. Male or female rats were given a single intraperitoneal injection of crystalline bovine insulin over a dose range of 2–20 units per animal, 5 min–2 h before pulse-labelling with ^{3}H-orotic acid. Fig. 3 shows the CCD patterns of *m*RNA after treatment with insulin for 5, 15 and 30 min. In the shortest time-period there appeared to be a general fall in the synthesis of *m*RNA per unit DNA. At 15 min there was a marked stimulation of a fraction in tubes 30–44, while at the same time diminution of other fractions was evident. By 30 min this pattern showed further change but still exhibited differences from the control curve. The patterns illustrated were obtained after treatment with large insulin doses (20 units) but similar selective action, less marked in degree, was observed with much smaller doses. The results of preliminary experiments with alloxan are illustrated in Fig. 4. Alloxan alone over 2 h changed the CCD pattern of *m*RNA, with enhancement of some peaks and diminution of others. Insulin given for 30 min after 1·5 h of alloxan produced a pattern somewhat different to that resulting from either alloxan or insulin alone for the respective time-periods. These results do not, of course, give any indication of the situation which prevails in diabetic animals.

Of the thyroid hormones, only the results of experiments with thyroxine are discussed here. Thyroxine was used over the dose range of 20–100 μg per animal, on male or female rats, over time-periods of 15 min–2 h. Fig. 5

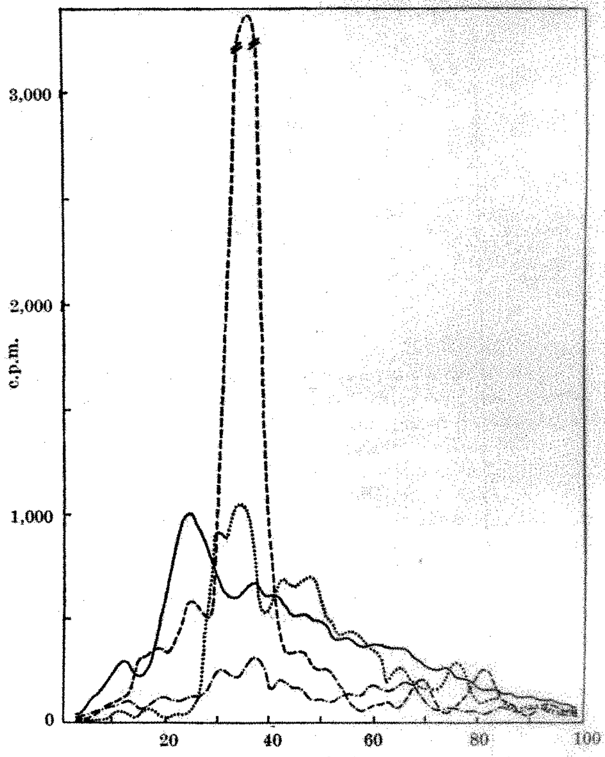

Fig. 3. Effects of insulin (20 units/rat) on *m*RNA patterns in rat liver. CCD in solvent system 150/12·5 over 100 transfers. ——, Control (*m*RNA from rat liver: 20 per cent protein diet); ————, *m*RNA from livers of rats receiving I.P.I. insulin 5 min before pulsing with ^{3}H-orotic acid; – – – –, *m*RNA from livers of rats receiving I.P.I. insulin 15 min before pulsing with ^{3}H-orotic acid; . . . . ., *m*RNA from livers of rats receiving I.P.I. insulin 30 min before pulsing with ^{3}H-orotic acid

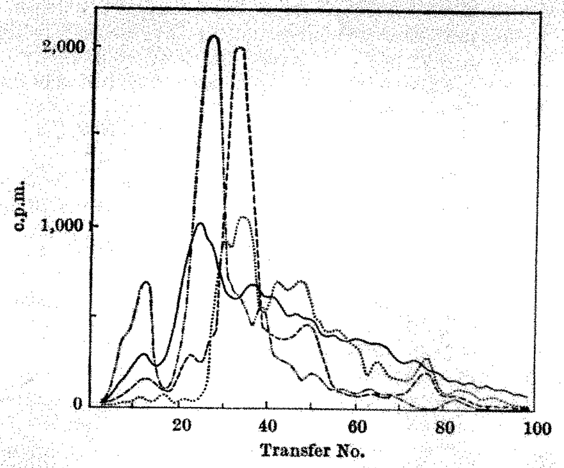

Fig. 4. Short-term effects of alloxan (5 mg/rat) ± insulin (20 units/rat) on *m*RNA patterns in rat liver. Fig. 5. Effects of thyroxine (30 μg/rat) and thiouracil (100 μg/rat) on *m*RNA patterns in rat liver. CCD in solvent system 150/12·5 over 100 transfers. ——, Control (*m*RNA from rat liver: 20 per cent protein diet); – – – –, *m*RNA from livers of rats receiving I.P.I. thyroxine for 15 min before pulsing with ^{3}H-orotic acid; . . . . ., *m*RNA from livers of rats receiving I.P.I. thyroxine for 1 h before pulsing with ^{3}H-orotic acid; —·—·—, *m*RNA from livers of rats receiving I.P.I. thiouracil for 2 h before pulsing with ^{3}H-orotic acid

shows the effects of thyroxine over two time-periods: from showing a major peak in tubes 28–40 at 15 min, the pattern became more heterogeneous by 1 h with increased synthesis of many peaks. The diminished synthesis of certain fractions evident at 15 min was no longer present at 1 h. Thiouracil appeared to cause some general depression of *m*RNA synthesis per unit DNA; the significance of the enhanced peak about tube 13 (Fig. 5) as of similar peaks in other experiments is uncertain: while it may well represent altered *m*RNA synthesis, residual ribosomal and soluble RNA remain in the first 20 tubes in this solvent system[31] and cannot be distinguished from *m*RNA in this region by CCD alone.

Testosterone was administered to male or female rats by intraperitoneal injection in an oily suspension in single doses of 0·1–1·0 mg per rat. CCD patterns are illustrated (Fig. 6) for *m*RNA pulse-labelled 1 h after testosterone injection. In the livers of male rats there was an increase in *m*RNA per unit DNA; this increase appeared to be a fairly general one involving most fractions as separated by CCD. In female rats somewhat different patterns were observed, the action being more selective.

Stilbœstrol was administered to male and female rats in doses of 0·1–1·0 mg per animal, in oily suspension given by intraperitoneal injection. CCD patterns are shown for a 1-h period in Fig. 7. In female rats there was a rather general increase in liver *m*RNA similar to that produced by testosterone in males. In male rats stilbœstrol appeared to have minimal effect on liver *m*RNA pattern.

The results of these experiments must be considered with certain reservations. The *m*RNA has been examined from a single source, rat liver, which is not necessarily a suitable target organ for examining the action of many hormones. A single radioactive pulse-time has been used for comparative purposes: for more complete information it would be necessary to investigate *m*RNAs synthesized at different rates. The time-periods of hormone action have been designated from the time of administration of hormone to the time of pulsing with radioactive label; since the pulse-time was 20 min the actual times of hormone action were considerably longer than specified, a factor especially important at the shorter times examined.

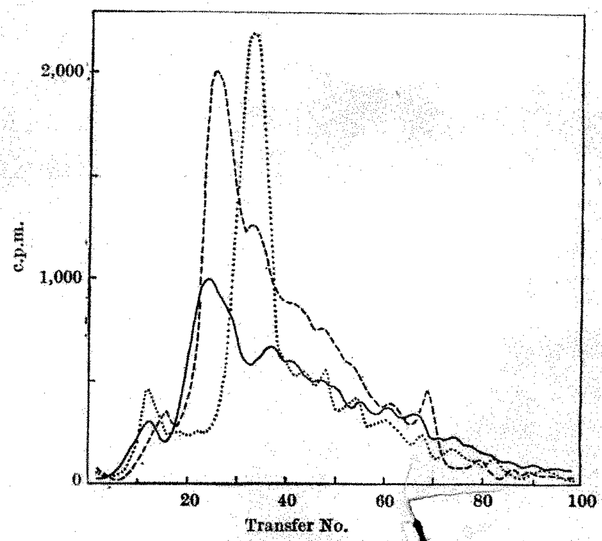

Fig. 6. Effects of testosterone (0·1 mg/rat) on *m*RNA patterns in male and female rats. CCD in solvent system 150/12·5 over 100 transfers. ——, Control (*m*RNA from rat liver: 20 per cent protein diet); – – – –, *m*RNA from livers of male rats receiving I.P.I. of testosterone 1 h before pulsing with ^{3}H-orotic acid; . . . . ., *m*RNA from livers of female rats receiving I.P.I. testosterone 1 h before pulsing with ^{3}H-orotic acid

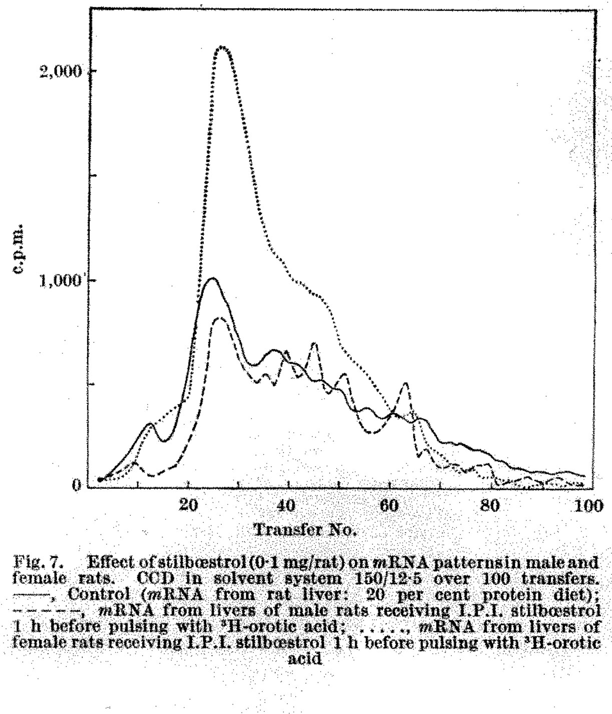

Fig. 7. Effect of stilbœstrol (0·1 mg/rat) on *m*RNA patterns in male and female rats. CCD in solvent system 150/12·5 over 100 transfers. ——, Control (*m*RNA from rat liver: 20 per cent protein diet); – – – – –, *m*RNA from livers of male rats receiving I.P.I. stilbœstrol 1 h before pulsing with ^{3}H-orotic acid; . . . . ., *m*RNA from livers of female rats receiving I.P.I. stilbœstrol 1 h before pulsing with ^{3}H-orotic acid

Where oily suspensions of steroid hormones were used no precise time-course of action can be ascertained owing to delays in absorption. For these reasons the present results cannot be considered to give any clear indication of the initial molecular sites of hormone action but only of early observed effects. Intact animals have been used exclusively and it is clear that detailed investigation of the actions of individual hormones on *m*RNA synthesis will need to examine the effects of endocrine ablation. It is clear, also, that many of the changes noted here may represent multiple effects and not necessarily the direct action of single hormones or their metabolites.

The use of countercurrent distribution to fractionate rapidly labelled RNA has revealed several features of this RNA in rat liver: (1) alteration of the pattern of synthesis of *m*RNA can be brought about by starvation or by hormones; (2) such changes are reversible; (3) both enhanced and diminished synthesis of various *m*RNA fractions occurs; (4) most hormones tested appeared to alter *m*RNA synthesis selectively, increasing some fractions and decreasing others; (5) hormone effects varied with time and in some cases selective alteration of *m*RNA synthesis was recognizable after a very short time.

These findings suggest that regulation of the synthesis of rapidly labelled mammalian RNA may be analogous to the regulation of synthesis of bacterial messenger RNA (refs. 10 and 35). While template activity has been reported for a similar fraction from rat liver[6] we have no indication that all rapidly labelled RNAs direct specific protein synthesis. However, the differential effects of changed environment (starvation) and of the small biologically active molecules (hormones) used would suggest that these RNAs are not precursors of ribosomal RNA (cf. Girard, Penman and Darnell[9]). The results clearly show the importance of fractionating the rapidly labelled RNAs for comparative purposes, rather than assessing gross quantitative change.

The exact manner in which hormones exert selective effects on gene transcription is not clear but the very early changes brought about by some of these hormones could indicate some direct action with the DNA-protein complex where the *m*RNA is synthesized. It could be that hormones interact with repressor proteins in an allosteric manner[36] resulting in altered patterns of synthesis of specific messenger RNAs. It is also possible that some of these rapidly labelled RNAs act directly as repressors at the DNA or ribosomal levels, or that they code for repressor proteins. Further fractionation followed by biological characterization of this RNA should permit a more precise definition of the molecular basis of these aspects of hormone action.

We thank Prof. A. Haddow for his advice. RELATIONSHIP OF LIVER COMPOSITION TO INTENSITY OF PROTEIN METABOLISM IN DIFFERENT MAMMALS

By Dr. H. N. MUNRO and Dr. EILEEN D. DOWNIE

Department of Biochemistry, University of Glasgow

AMONG mammals, the intensity of protein metabolism per unit of body-weight becomes progressively smaller with increasing size of species[1]. This is demonstrated by the rate of exchange of nitrogen-15-labelled amino-acids with tissue proteins, by the amount of urinary nitrogen excreted by animals receiving a protein-free diet (endogenous urinary nitrogen), and by the rate of turnover of plasma albumin in various species[1]. Each of these parameters of protein metabolism bears a relationship to body size that follows approximately the 0·7 power of body-weight. Consequently, the intensity of protein metabolism per kg body-weight is about five times greater in an adult rat of 200 g weight than in an adult man weighing 70 kg.

It might be anticipated that these differences in protein metabolic rates of mammals would affect the concentrations of nucleic acids in their tissues, since the nucleic acids are concerned with protein synthesis. Although the published literature[2] contains many estimates of the RNA and DNA concentrations made on mammalian tissues, the considerable errors[3] inherent in most of the assay procedures used in these investigations make strict comparisons between species impossible. We have therefore examined the concentrations of nucleic acids and other cell constituents in the livers of a range of mammals using a uniform procedure, and have related the findings to body size and to intensity of protein metabolism.

The livers examined were those of adult mice, rats, rabbits, dogs and cows receiving their normal diet. Pieces from different lobes of the liver were excised at death. The portions from the liver of 2–6 animals of each species were then pooled for analysis. These were first homogenized in 0·25 M sucrose. Part of the homogenate was retained for whole tissue analysis, and the remainder was spun in a refrigerated centrifuge at 8,500*g* for 10 min to remove nuclei, mitochondria and unbroken cells. The supernatant fraction from this spin was centrifuged for 60 min at 105,000*g* to precipitate the microsomes, which are remnants of the endoplasmic reticulum of the intact cell.

The whole homogenate and the microsome fraction were analysed for nucleic acids, protein and phospholipid content. A modification[4] of the Schmidt–Thannhauser procedure was used for analysis of RNA and DNA. Protein content was estimated after treating samples of the homogenate or microsome fraction with 10 per cent trichloroacetic acid; the nitrogen content[5] of the precipitated material, corrected for nucleic acid and phospholipid nitrogen, provided a measure of the amount of protein. Phospholipid content was obtained by extracting portions of the trichloroacetic acid precipitate with a series of organic lipid solvents[6] and estimating[7] the phosphorus contained in the combined extracts.

Table 1 shows the total amounts of various liver constituents. When expressed per kg body-weight, individual constituents are seen to diminish with increasing size of species. In order to obtain equations describing the effect of body size, the logarithms of the total amount of each liver constituent were plotted against the logarithm of body-weight. In each instance, the relationship approximated closely to a straight line, from which the exponents (Table 2) relating each liver constituent to body-weight were obtained by computing regression equations.

Table 1. LIVER WEIGHT AND COMPOSITION IN RELATION TO BODY-WEIGHT IN A SERIES OF MAMMALS OF DIFFERENT BODY SIZE*

Species	Body-weight (kg)	Total liver content per kg body-weight				
		Wet weight (g)	Protein (g)	Phospholipid (mg)	DNA (mg)	RNA (mg)
Mouse	0·03	53	10·8	1,800	126	560
Rat	0·16	35	7·3	1,190	122	375
Rabbit	2·05	35	6·8	1,000	88	207
Dog	16·0	24	5·6	770	80	138
Cow	400·0†	10	1·9	360	41	53

* Livers from 2–6 animals of each species were analysed.
† Approximate mean weight of group.

Although the various measurements of intensity of body protein metabolism are related to approximately $\mathrm{Wt}^{0\cdot7}$ (Table 2), the total weight of the liver does not diminish so rapidly with increasing body size. From our results, this relationship is expressed by $\mathrm{Wt}^{0\cdot84}$ and from Brody's[8] compilation by $\mathrm{Wt}^{0\cdot87}$. Several liver constituents (protein, phospholipid and DNA content) follow the same relationship to body-weight, but the RNA content of the liver declines as $\mathrm{Wt}^{0\cdot75}$, and is thus more closely related to the effect of body size on body protein metabolism.

The more marked effect of body size on the RNA content of the liver cell is also demonstrated by computing the RNA/DNA and phospholipid/DNA ratios for the livers of different species (Table 3). The extensive decline in the RNA/DNA ratio with increasing body-weight can be contrasted with the relatively slight influence of body size on the phospholipid/DNA ratio (Table 3). The difference is also seen on analysis of the microsome fraction (Table 3), in which a considerable reduction in the percentage of RNA in the microsomes of the larger mammals is accompanied by a small increase in their phospholipid content. Phospholipid is a component of the membranous portion of the microsomes, whereas RNA is contained in the ribosomes attached to the membrane surface. Our observations thus suggest that, in the liver cells of larger animals, there are fewer ribosomes attached to the membranous part of the endoplasmic reticulum, from which the microsomes are formed on homogenization.

Table 2. EFFECT OF BODY SIZE OF MAMMALS ON THE INTENSITY OF PROTEIN METABOLISM AND ON THE TOTAL AMOUNTS OF VARIOUS LIVER CONSTITUENTS

Measurement	Exponent* relating measurements to body-weight
Metabolic measurements‡	
Endogenous urinary N (mg N/day)	0·72
Total body protein synthesis (mg ^{15}N incorporated/day)	0·75
Plasma albumin turnover (days^{-1})	0·66
Total liver constituents†	
Wet weight (g/liver)	0·843
Protein (g/liver)	0·835
Phospholipid (mg/liver)	0·842
DNA (mg/liver)	0·884
RNA (mg/liver)	0·755

* This is the exponent $^{(x)}$ in the equation: observed quantity per animal = a constant X (body-weight)^{x}. It is computed from the slope of the line relating the logarithm of the observations to the logarithm of body-weights.
† Computed from the results given in Table 1. The relationship of liver weight to body size, based on a survey of published data, was found by Brody[8] to follow $\mathrm{Wt}^{0\cdot87}$. From an examination of female mice, rats and guinea pigs, Kosterlitz[9] obtained an exponent of 0·85 for the relationship of the DNA content of the liver to body-weight.
‡ For references, see Munro[1].

Table 3. PLASMA ALBUMIN TURNOVER, LIVER CELL COMPONENTS PER mg DNA, AND COMPOSITION OF LIVER MICROSOMES OF DIFFERENT MAMMALS

Species	Half-life of plasma albumin* (days)	Whole liver composition† (mg/mg DNA)		Microsome fraction (per cent of estimated constituents)		
		RNA	Phospholipid	RNA	Phospholipid	Protein
Mouse	1·2	4·45	14·2	9·6	24·2	66·2
Rat	2·5	3·05	9·8	7·3	22·9	70·0
Rabbit	5·7	2·44	11·6	6·2	29·2	64·5
Dog	8·2	1·69	9·4	—	—	—
Cow	20·7	1·29	8·7	5·9	31·3	62·7

* Results reported by Dixon, Maurer and Deichmiller[10]; the value for the rat is that given by Allison[11].
† Computed from the results given in Table 1.

The endoplasmic reticulum of the liver cell is considered to function in the formation and secretion of plasma proteins. The rate of formation of plasma albumin diminishes with increasing body size (Table 3), and our findings indicate a parallel decrease in the total RNA content of the liver and in the amount of RNA in the microsomes. Absence of a similar correlation with the amount of phospholipid contained in the cell and in the microsomes suggests that, although phospholipid is also a constituent of the endoplasmic reticulum, it is less directly concerned with protein formation.

This investigation was supported by a grant to one of us (H. N. M.) from the Advisory Committee on Medical Research of the Department of Health for Scotland.

MULTIPLE FORMS OF CHOLINESTERASE IN HORSE PLASMA

By Dr. Y. OKI*, Prof. W. T. OLIVER and Dr. H. S. FUNNELL
Ontario Veterinary College, Guelph, Canada

THE number of publications dealing with multiple forms of various enzymes has increased rapidly since the introduction by Smithies[1] of starch-gel electrophoresis. Using this technique, Markert and Moller[2] separated lactic dehydrogenase into several molecular forms which they named 'isozymes'. Multiple forms of serum esterases and cholinesterases also have been reported to occur in human and animal sera[3-6]. In extensive human family investigations, Harris, Hopkinson and Robson[7] demonstrated electrophoretically a new genetically controlled variant of serum cholinesterase. This article is concerned with multiple forms of equine plasma cholinesterase, some biochemical characteristics and a genetically controlled variant.

Plasma samples were obtained from 94 horses and the plasma esterases were separated by vertical starch-gel electrophoresis[8] using the discontinuous buffer system[9]. The esterases were characterized using as substrates: α-naphthyl acetate, β-naphthyl acetate, α-naphthyl propionate, α-naphthyl butyrate, α-naphthyl caprylate, naphthol AS acetate, naphthol AS-D acetate and β-carbonaphthoxycholine iodide. Eserine and TEPP were used as inhibitors. Each fraction was eluted from the starch gel using *tris* buffer and its activity was determined spectrophotometrically[10] using benzoylcholine as the substrate. A 'zymogram' is shown (Fig. 1) of the esterase zones detected following electrophoresis and staining with α-naphthyl acetate and naphthanil diazo blue B in phosphate buffer *p*H 6·8

Seven zones, C_1, C_2, C_3, C_4, B, A_1 and A_2, were present in all equine plasma samples examined, C_2 usually being a doublet. Two other zones, C_5 and D, were present in only 4 and 12, respectively, of the samples. Since zones C_1, C_2, C_3, C_4 and C_5 hydrolysed all substrates and benzoylcholine and their activities were inhibited by eserine and TEPP, 10^{-5} M, they were considered to be multiple forms of pseudocholinesterase.

Zone B hydrolysed both the short- and long-chain fatty acid esters but was insensitive towards β-carbonaphthoxycholine iodide and benzoylcholine. It was not inhibited by eserine, 10^{-5} M, but was inhibited by TEPP, 10^{-4} M. Thus it was concluded that zone B contained an aliesterase but not a cholinesterase.

Zone A_2 hydrolysed α- and β-naphthyl acetate, naphthol AS acetate and naphthol AS-D acetate, but not the choline esters, and was not inhibited by eserine or TEPP, 10^{-5} M ~ 10^{-4} M. It appeared that this zone contained an arylesterase but not a cholinesterase.

Zone A_1 had a mobility corresponding with that of albumin. It hydrolysed α- and β-naphthyl acetate, naphthol AS acetate and naphthol AS-D acetate, but did not hydrolyse choline esters. Its activity was not inhibited by eserine or TEPP, 10^{-5} M ~ 10^{-4} M. This zone, containing an aromatic esterase-like activity, probably corresponds to the 'albumin esterase' in human plasma reported by Wilde *et al.*[11].

Zone D hydrolysed only the four short-chain fatty acid esters, α- and β-naphthyl acetate, α-naphthyl propionate and α-naphthyl butyrate, but did not utilize β-carbonaphthoxycholine iodide or benzoylcholine. Its activity was inhibited by TEPP, 10^{-5} M, and eserine, 10^{-4} M, but was partially resistant to eserine 10^{-5} M. It was concluded that this zone was a type of ali-esterase differing from zone B.

Zone LP, a lipoprotein, had the least mobility of the zones observed. It stained slightly with β-naphthyl acetate-dye solution and was identified using sudan black.

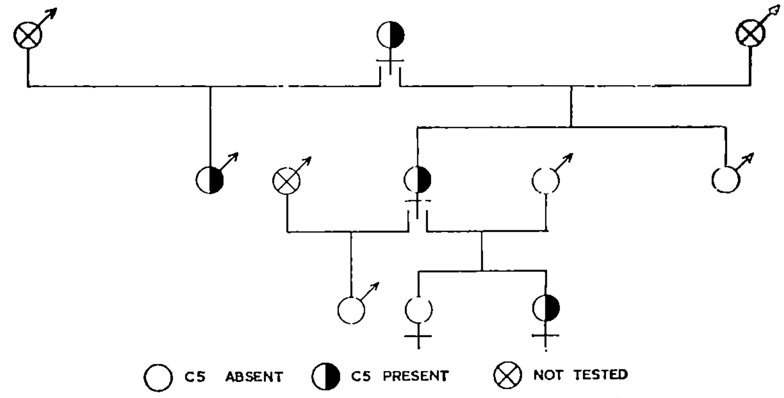

Fig. 3. Pedigree of family in which zone C_5 is segregating

---

* Postdoctorate Fellow, National Research Council (Canada).

The hydrolysis of α-naphthyl acetate by zones C_1, C_2 and D was usually weak (Fig. 2*a* and *d*). However, the plasma of certain individuals contained at least one of these zones with considerably greater activity than the average (Fig. 2*b* and *e*). This property appeared to be a constant individual characteristic which was not related to age, sex or breed.

The esterase patterns of the thoroughbred, standardbred, quarter horse, Arab and pony, that is, light horses, were similar, and all lacked zone D, which was common to two of the draft breeds, Belgian and Percheron (Fig. 2*d* and *e*), but not the third, Clydesdale.

Zone C_5 (Fig. 2*c*) was present in only four of the 94 samples examined, these four being members of the same family (Fig. 3). This zone appeared in fresh plasma samples obtained over a six-month period and was not affected by incubation or freezing. The family investigation suggested that this zone, a cholinesterase, may be genetically controlled; each individual may be a heterozygote for an autosomal gene which determines the presence of this component as a phenotype.

From these preliminary investigations, it appeared that: (1) There were four zones of cholinesterase activity in all samples examined; one of these, C_2, was usually a doublet. (2) Zone C_5, a variant form of cholinesterase, may be genetically controlled. (3) Zone B, an ali-esterase, hydrolysing short- and long-chain fatty acid esters, was present in all samples. (4) Zone D, a type of ali-esterase utilizing short-chain fatty acids only, was present in two of three draft breeds examined. (5) Equine plasma contains two arylesterases, one probably corresponding to 'albumin esterase' of human plasma.

MECHANISMS OF INACTIVATION OF SINGLE-STRANDED VIRUS NUCLEIC ACIDS BY HEAT

By WILLIAM GINOZA, CAROL J. HOELLE*, KRISTIN B. VESSEY and CECIL CARMACK*

Biophysics Department, Pennsylvania State University, University Park

THE two classes of infectious single-stranded virus nucleic acids, exemplified by RNA of tobacco mosaic virus (TMV) and by φ*X*174-DNA, are found to exhibit a marked difference in their response to heat in the physiological *p*H range. This is reflected in the gradual decay of both infectivity and molecular integrity of RNA on storage under conditions in which the single-stranded DNA is stable. Instability and the attendant molecular heterogeneity have in large measure contributed to the difficulty in past attempts to measure the size of the intact and infectious TMV–RNA molecules[1,2]. Heterogeneity could arise from random scission of phosphodiester bonds which hold constituent ribose-nucleotides in a single continuous chain. Kinetic evidence has been presented earlier to suggest that spontaneous decay of TMV–RNA is related to the inherent susceptibility of its phosphodiester bonds to heat-induced hydrolysis[3]. Work of Gordon and Huff[4] and of Eigner, Boedtker and Michaels[5] support this conclusion. However, it is still widely believed that the instability is due mainly to seemingly ubiquitous nucleases carried over into RNA preparations as contaminants.

On the other hand, phosphodiester bonds of single- and double-stranded DNA are stable under thermal treatment at neutral *p*H, but DNA in either form is relatively sensitive to depurination[6-8]. A loss of a single purine is sufficient to destroy the function of a single-stranded cyclic φ*X*174–DNA[8] and presumably that of a genetic marker in transforming DNA[7].

We examine here the kinetics of inactivation of three single-stranded nucleic acids, TMV–RNA, *R*17–RNA and φ*X*174–DNA, under comparable conditions of thermal treatment. The results obtained over a range of *p*H and temperature indicate that the two classes of nucleic acids are inactivated by distinctly different first-order processes. They are consistent with the conclusion that cleavage of a single phosphodiester bond inactivates the RNAs while a single depurination inactivates φ*X*174–DNA.

Preparation of virus nucleic acids. TMV–RNA, *R*17–RNA, and φ*X*174–DNA were prepared essentially by the method of Gierer and Schramm[9], except that the nucleic acid extracts following the phenol treatment were precipitated repeatedly with 95 per cent ethanol to eliminate traces of phenol. Reagent-grade phenol was washed five times with 10^{-4} M versine before use. The parent viruses were purified by differential centrifugation. Heat sensitivity of the nucleic acids obtained from them was found to be independent of the purification steps taken prior to the final centrifugation of the viruses.

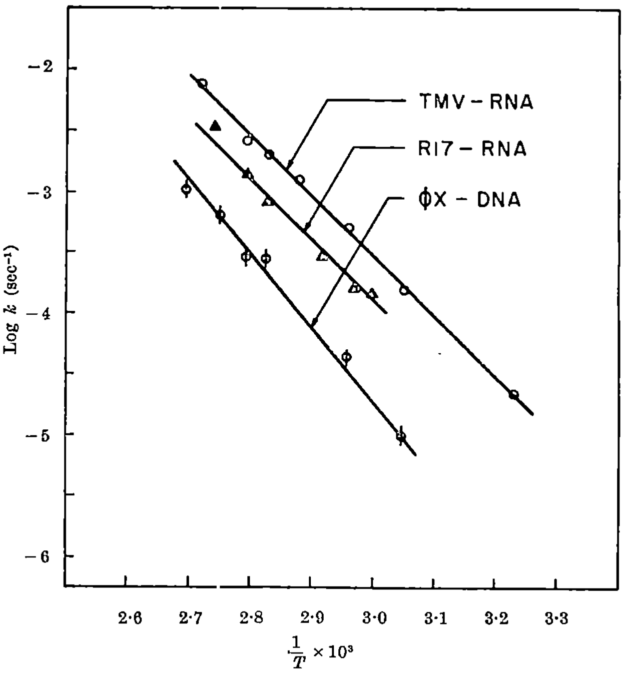

Fig. 1. Temperature-dependence of the rates of inactivation of TMV-RNA, *R*17-RNA and φ*X*174-DNA by heat in 0·1 M sodium phosphate buffer, *p*H 7·15

---

* Address: University of California at Los Angeles.

Bioassays of these nucleic acids were conducted in manners described in our previous papers[3,11,12].

TMV–RNA, *R*17–RNA and φ*X*174–DNA are all heat-inactivated by a first-order rate law at each temperature and *p*H examined. Their rates show no obvious dependence on concentration at which they are heated. The rate constants of inactivation of the nucleic acids in 0·1 M sodium phosphate buffer at *p*H 7·15 are plotted against temperature and are summarized in Fig. 1. It is immediately apparent that TMV–RNA, though only 1·2 times larger in size than φ*X*174–DNA, is more sensitive to heat than the latter by a factor ranging from 10 at the higher experimental temperature to about 30 at 37°. *R*17–RNA is intermediate in position, its rates of kill being nearly one-half that of TMV–RNA at all temperatures examined. The ratio of the molecular weight of TMV–RNA[11,13–15] to that of *R*17–RNA, $2·0 \times 10^6/0·8 \times 10^6 = 2·5$, corresponds well to the ratio of their rate constants, 2·3. The rates, for example, at 80° for TMV–RNA, *R*17–RNA and φ*X*174–DNA are $1·93 \times 10^{-3}$/sec, $8·3 \times 10^{-4}$/sec and $2·83 \times 10^{-4}$/sec, respectively.

This correlation, together with the closeness of the thermal constants (Table 1) derived from the plot (Fig. 1), suggests that the two RNAs are inactivated by the same mechanism but with rates in direct proportion to their chain-lengths. If such a proportionality is meaningful, it would predict the much smaller, soluble RNA to be a great deal more stable to heat inactivation. Indeed, a very close correspondence has been observed[16]. Gordon *et al.*[17] also showed that TMV–RNA and polio-virus RNA possessing the same molecular weight[1] are heat inactivated at about the same rate.

Table 1

	Medium	*p*H	ΔH^* (kcal/mol.)	ΔS^* (E.U.)	Temp.-range

† Sodium dodecyl sulphate used for deproteinization (ref. 3).

The second feature of interest is the magnitude of the thermodynamic constants, ΔH^* and ΔS^*, derived from the Arrhenius curves shown in Fig. 1. Our previous values for ΔH^* and ΔS^* were 19 kcal/mol. and −19·5 E.U., respectively, for TMV–RNA prepared by using sodium dodecyl sulphate for deproteinization of the parent virus[3]. The thermal constants for the phenol-prepared *R*17–RNA, however, are in close agreement with the present values for the similarly prepared TMV–RNA. The values for φ*X*174–DNA, particularly the small ΔS^*, suggest a significant difference from those of the two RNAs at the same *p*H, 7·15 (see Table 1 for values at other *p*Hs). The moderate values of ΔH^* obtained for both types of nucleic acids are consistent with inactivation mechanisms involving breakage of a single covalent bond as opposed to co-operative rupture of a large number of hydrogen bonds characteristic of a denaturation reaction. This observation should be taken into consideration when discussing the relevance of secondary structure, reported to exist in various types of RNA[2], to function.

The third notable feature of the Arrhenius plots for the RNAs is their linearity over a wide range of temperature, particularly for TMV–RNA. This suggests that the single-reaction mechanism apparently operating on the RNA over this temperature range is not enzymatic, unless the temperature of maximum enzyme activity of the hypothetical contaminant is 96° or higher.

The experimental results showing the dependence of heat-inactivation rates of *R*17–RNA and φ*X*174–DNA on *p*H are summarized in Figs. 2 and 3. Inactivation rates were measured in Michaelis's 'universal' buffer[18], which circumvents possible specific effects of the buffer ions while keeping the ionic strength reasonably constant over the experimental *p*H range. It is seen from comparing the two plots of rate constants versus *p*H, for example at 70°, that there is a striking contrast between RNA and DNA in their response to *p*H (Fig. 4). For *R*17–RNA, as

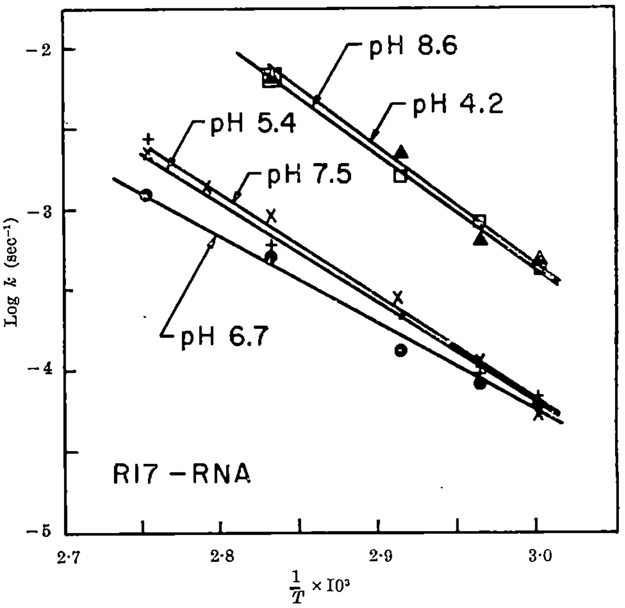

Fig. 2. Temperature-dependence of the rates of heat-inactivation of *R*17-RNA at various *p*H in Michaelis buffer (ref. 18)

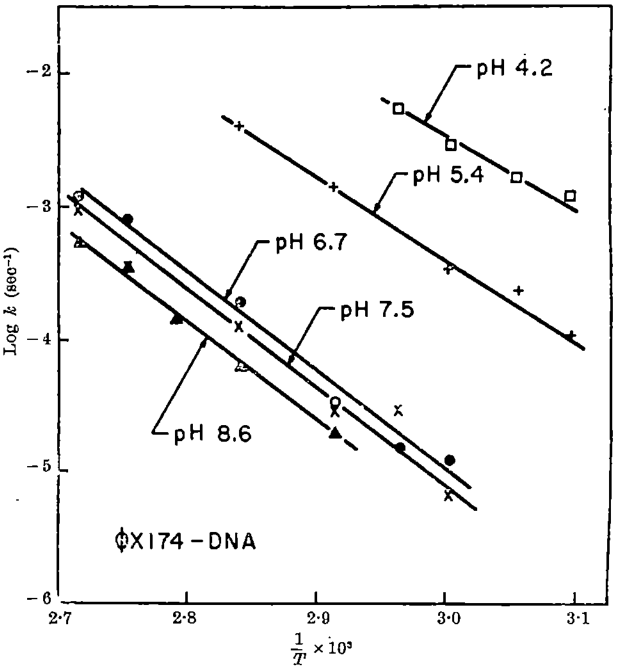

Fig. 3. Temperature-dependence of the rates of heat-inactivation of φ*X*174-DNA at various *p*H in Michaelis buffer

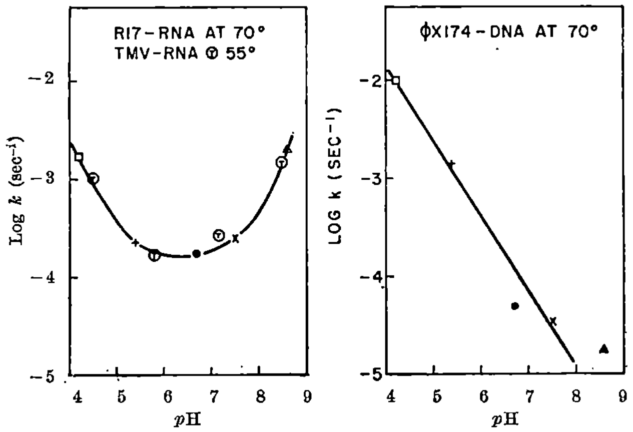

Fig. 4. pH dependence of the rates of inactivation of R17-RNA at 70°, TMV-RNA (T) at 55° and φX174-DNA at 70° in Michaelis buffer. Rate constants for R17-RNA and φX174-DNA are transposed from Figs. 2 and 3

well as for TMV–RNA, the pH of maximum stability is 6–6·5 with progressively increasing sensitivity on either side of this range. This is to be expected if we are to assume that hydrolytic scission of a phosphodiester bond is the cause of the inactivation, for it is known that hydrolytic degradation of RNA is both acid- and alkali-catalysed[19]. The corresponding curve for φX174–DNA shown in Fig. 4, on the contrary, shows that DNA is most stable at the highest pH tested, 8·6, and shows an increasing heat sensitivity with decreasing pH. Vinograd[20] and Fiers and Sinsheimer[8] have shown that φX174–DNA is stable even at pH 12 and, moreover, the latter's data indicate that the inactivation rate of this DNA increases approximately as the first power of the hydrogen ion concentration. Our results in a different buffer system recorded here confirm their findings (Fig. 4). This behaviour is expected from the known chemistry of depurination. The thermal constant, $\Delta H^* = 35$ kcal/mol. at pH 7·5, compares with 34 kcal/mol. over a temperature range of 91°–100° for the single-stranded, transforming DNA in pH 7·15 sodium phosphate buffer[7], and with 35 kcal/mol. for φX174–DNA in glycine buffer, pH 9·0 (ref. 8). In the latter systems depurination was shown to be the most likely cause of inactivation, the reaction course of which follows a 'one-hit' kinetics, and also their evidence shows that chain cleavage is not necessarily a concomitant process, although the phosphodiester bond at the site of depurination may be weakened[21].

It is to be recalled that transforming DNA is heat-inactivated by two principal mechanisms, namely, depurination and denaturation[7,24]. Depurination at temperatures below the melting transition (< 87°) requires very high activation energy as indicated by a rapid decrease in the inactivation rates with decrease in temperature (ref. 7, Fig. 6). This points to a necessity for localized and reversible chain opening of the double helix before a glycosidic bond of a purine can be hydrolysed. Accordingly, the depurination rate for double-stranded DNA is expected to be immeasurably slow compared at 37° to that of the single-stranded φX174–DNA.

It is also worthy of note that the pH of maximum stability for TMV–RNA, as well as for R17–RNA, is close to the pH of maximum activity of tobacco leaf RNase[22,23], a possible contaminant in the former preparation. This fact, taken together with the linearity of the Arrhenius plots shown in Fig. 1 and the reproducibility of the inactivation rates among numerous RNA samples, eliminates nucleases as agents responsible for the inactivation kinetics observed in this series of experiments, at least in the case of TMV–RNA.

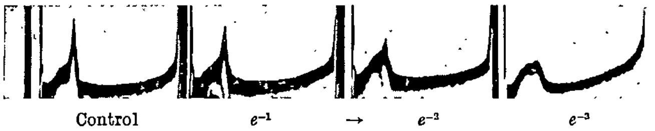

Fig. 5. Ultracentrifuge patterns of TMV-RNA (0·036 per cent in 0·02 M sodium phosphate buffer, pH 7·0) at various levels of survival following heat treatment at 65° in 0·1 M sodium phosphate buffer, pH 7·15. Each picture was taken 64 min after the rotor speed reached 24,630 r.p.m. Bar angle, 15°

In the case of RNA it seems possible that physical methods could provide more direct evidence that chain scission results from one inactivating hit by heat, as single scission should effect a drastic change in its molecular weight. Attempts at correlating the kinetics of biological inactivation of TMV–RNA to physical degradation have been reported[2,3a,15]. Interpretations of these results are, however, beset with serious difficulties, because the usual RNA preparations on which the foregoing kinetic investigations are performed are polydisperse to begin with and the demonstrable biological activity is due to a fraction (~ 0·1 per cent) of the population which is not detectable by conventional physical tools. For example, $S_{20,w}$, usually obtained for the leading main peak seen with the schlieren optics, is 25, from which we calculate a weight average molecular weight of about $1{\cdot}3 \times 10^6$, whereas the molecular weight of the intact biologically functional RNA is $2{\cdot}2 \times 10^6$ (ref. 11). This fact, incidentally, is one of the reasons for the application of radiation target analysis[11]. However, assuming that the physical characteristics of the bulk RNA reflect the properties of the infectious molecules, we have followed the course of molecular degradation by analytical ultracentrifugation and viscometry of TMV–RNA samples heat-inactivated in 0·1 M sodium phosphate buffer, pH 7·15, to e^{-1}, e^{-2} and e^{-3} surviving population. It is found (Fig. 5) that the leading peak decreases in area progressively with each inactivating hit with a concomitant increase in the trailing more diffuse peak, while the intrinsic viscosity falls from 1·92 for the unheated control to 1·59 dl./g for the sample receiving 3 inactivating hits. Allowing the assumption made here, these results support the conclusion that heat inactivation is a direct consequence of a chain scission. Moreover, on very prolonged heating of TMV–RNA in the same buffer but at higher temperatures, poly- and mono-nucleotides and nucleosides but no free bases are found, whereas under comparable treatment calf-thymus DNA yields the expected free purines. This demonstrable stability of glycosyidic bonding of purines to ribose excludes depurination as a significant factor in heat inactivation of RNA.

The striking difference in the behaviour of the phosphodiester bonds of the two types of nucleic acids arises essentially from their chemical difference, namely, that RNA possesses a 2′ OH function in its sugar moiety whereas DNA does not. The effect of acid-base catalysis on the rate of hydrolysis of the phosphodiester bonds of RNA has been long recognized, as has the stability of DNA in alkaline medium. On the basis of their work with model compounds, α- and β-glycerophosphates, Brown and Todd[25] proposed the reaction sequence in Fig. 6 to explain the special lability of the phosphodiester bonds of RNA.

They postulated that the formation of the cyclic phosphate-triester intermediate, B, is essential in order to explain the production of the two isomers, E and F, following alkaline hydrolysis of RNA. The formation of B is possible because of the 2′ OH function, and product C results because of the instability of the triester structure, in which one of three ester linkages becomes sensitive to hydrolysis. Product C, being a diester, is relatively stable at neutral pH and in moderately alkaline medium[4,26].

The thermal constants for both TMV–RNA and R17–RNA (Table 1) are consistent with the Brown and Todd reaction mechanism. The negative entropy of activation, ΔS^*, derived for TMV–RNA and R17–RNA, agrees with the formation of cyclic structure B, the activated state of

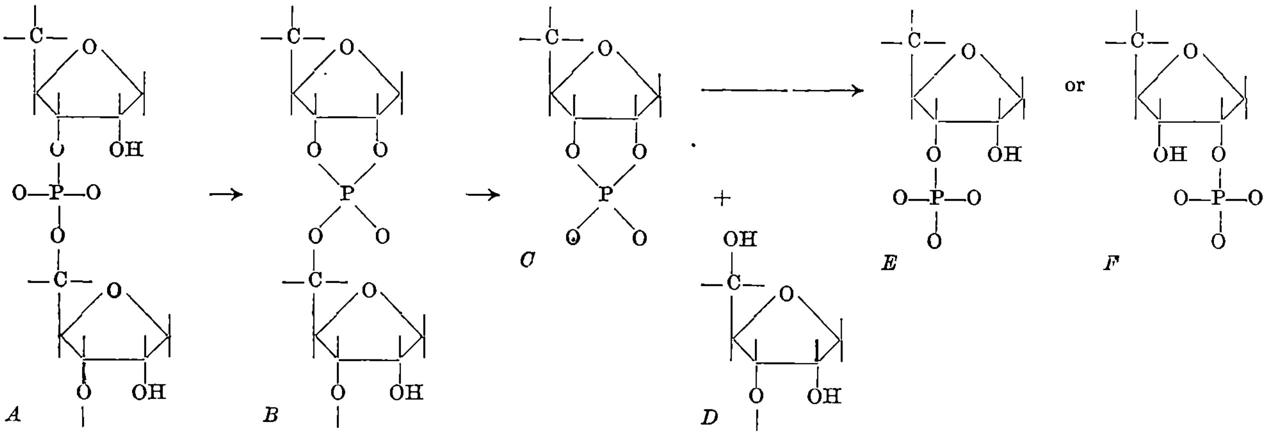

Fig. 6

the RNA molecule, which prepares the phosphodiester backbone for hydrolytic cleavage[3]. Experimental evidence for the involvement of the cyclic intermediate in heat-inactivation of TMV–RNA is shown in the recent work of Gordon and Huff[4].

The entropy of activation for the two RNAs on either side of neutrality (Table 1) becomes increasingly more positive in apparent contradiction to the cyclic mechanism. The reason for the rise may be that acid and base catalysis greatly increases the rate of cyclization so that hydrolysis of the third ester bond, rather than the formation of the cyclic triester, becomes the rate-limiting step in the inactivation (cf. ref. 19).

The demonstrated propensity of the phosphodiester bonds of RNA to disjoint easily without the mediation of enzymes leads us to consider its possible bearing on the short life[27] of messenger-RNA in microbial systems; for it is conceivable that the function of *m*RNA, like the viral RNA *in vitro*, can be disrupted by a single, random scission of these bonds.

As for DNA, in particular at 37°, we conclude that: (1) it is 30 times less susceptible in the single-stranded form to heat-inactivation by depurination than is a comparable-sized RNA to inactivation by phosphodiester backbone scission; (2) because of the large entropy term involved, depurination rate of the double-stranded DNA should be immeasurably slow relative to that of the single-stranded form at this temperature.

We thank Miss Jean E. Kinnear for the ultra-centrifugal analyses and Drs. William Taylor and Joseph Steim for their advice. Part of this work was performed at the Department of Biophysics and Nuclear Medicine, University of California at Los Angeles.

This work was carried out under contract *AT* (30–1)–3116 with the U.S. Atomic Energy Commission.

OPTOKINETIC NYSTAGMUS: AN UNLEARNED RESPONSE ALTERED BY SECTION OF CHIASMA AND CORPUS CALLOSUM IN MONKEYS

By DR. TAUBA PASIK and DR. PEDRO PASIK
Department of Neurology, Mount Sinai Hospital, New York

MUCH work has been done in recent years on the role of the corpus callosum in the so-called interhemispheric transfer of learning[1]. Little attention has been directed, however, to the influence of commissural systems in other forms of behaviour, particularly in those which depend scarcely, if at all, on past experience. This article shows that the section of the corpus callosum also disrupts an unlearned response such as optokinetic nystagmus. In this type of behaviour there is a visual input consisting of successively moving stimulus-figures across the visual field, and an oculomotor output manifested by slow conjugate eye deviations in the direction to which the stimuli move, alternating with similar fast movements to the opposite side. Conventionally, the direction of the response is named by the quick phase. In the monkey, output usually outlasts the duration of the stimulus and this is known as optokinetic after-nystagmus.

In primates, as well as in most vertebrates, visual input from homonymous (right or left) half fields of both eyes is conveyed to the opposite half of the brain in a totally crossed fashion[2]. Similarly, pathways for conjugate gaze descend from most of the cerebral cortex towards the brain stem and decussate completely about the level of the third nerve nucleus, as demonstrated in numerous ablation and stimulation experiments[3]. From this latter work it also followed that the efferent pathways responsible for the fast phase of optokinetic nystagmus are the same as those for conjugate gaze. Fig. 1 is a diagram which summarizes some of these functional

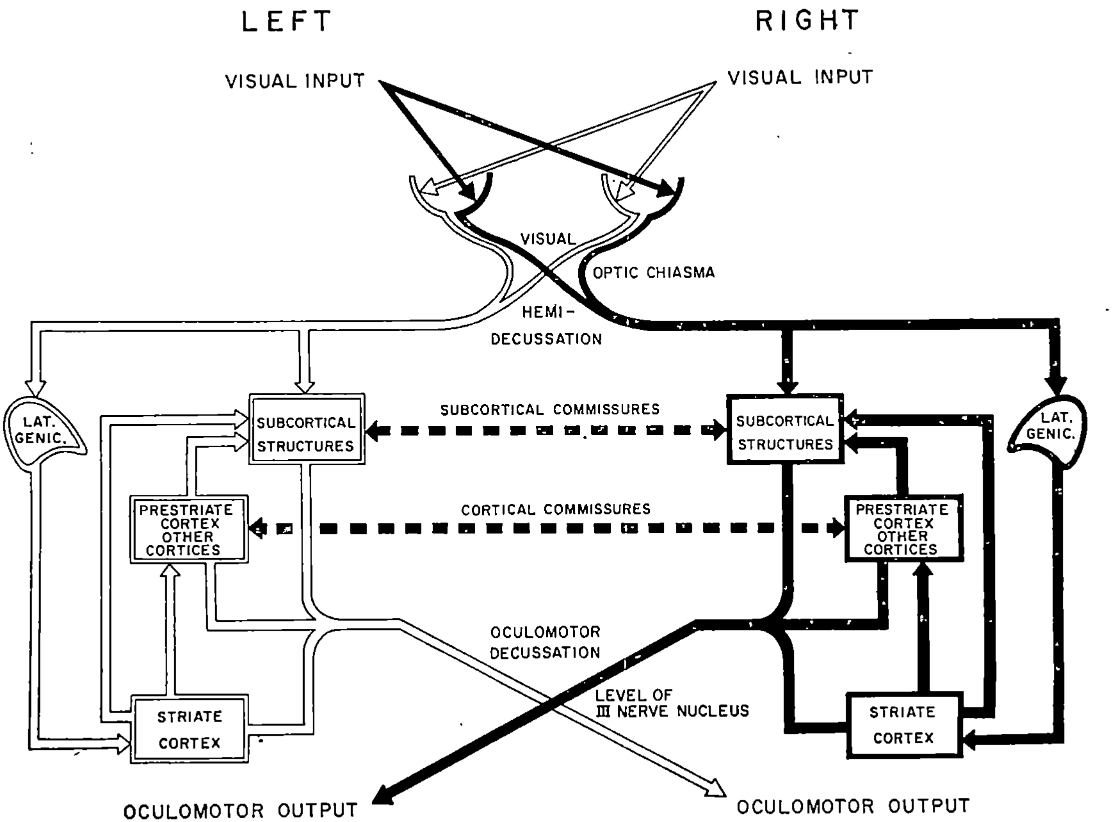

Fig. 1. Functional diagram of visual and oculomotor systems in the monkey. Solid black indicates visual input from the left, reaching the right side of the brain where it initiates oculomotor output to the left (conjugate gaze, fast phase of optokinetic nystagmus). Open lines represent just the opposite functions. Dashed black indicates commissural systems

facts about the visual and oculomotor systems. It should not be taken as representing strict demonstrable anatomic connexions, many of which are still in the process of study and revision. Specifically, visual input from the left field reaches the two right hemi-retinæ and through the hemidecussation at the chiasma conveys the information to the right hemisphere at the cortical level (via the lateral geniculate nucleus to striate cortex) and at the subcortical level (several known and many uncertain structures). The striate cortex projects to the prestriate region and to subcortical areas. Oculomotor outflow may be initiated from striate, prestriate, most of the rest of the cortex as well as from subcortical structures and conveyed through pathways that cross totally about the level of the third nerve nucleus, to drive the eyes to the left. In addition there are commissural systems at cortical and subcortical levels.

While the input and output, that is, visual stimulus and oculomotor response, are rather clear in optokinetic nystagmus, the events in between, the integrating mechanisms inside the central nervous system, are still unknown. Some years ago, we examined the effect of cortical ablations on optokinetic nystagmus in the monkey. Contrary to what might be expected from the previous considerations, unilateral total removal of striate cortex failed to cause any deficit in the response to the side opposite the lesion[4]. After right occipital lobectomy, optokinetic nystagmus was normal and symmetrical to the right and to the left.

The question arose as to how the unilateral visual stimuli are utilized to elicit an optokinetic response to the left in the absence of the right striate cortex. Two basic hypotheses may be formulated to explain this finding. They may be easily followed by referring to Fig. 1. (1) It may be that input from the left visual field is still essential. This input would reach subcortical structures on the right side of the brain which in turn would activate the oculomotor pathways that drive the eyes to the left. (2) It may be, on the other hand, that input now from the right visual field reaches the striate cortex and subcortical areas in the left side of the brain, and from here, by way of commissures, activates areas of the right side of the brain which in turn would stimulate the oculomotor pathways for conjugate gaze to the left.

The work presented here was carried out to test some of these hypotheses. Six monkeys (2·5–3·1 kg) were used. Optokinetic nystagmus was elicited by placing the animal inside a rotating cylinder, 92 cm in diameter, which filled the entire visual field with alternating 2·5-cm black and 33-cm white stripes. This drum could be rotated at constant speed by means of a servo-motor. Details of construction have already been published[3,4]. Stimulation was made binocularly and also with each eye separately with the aid of an opaque sclerocorneal contact occluder. Eye movements were recorded with an electroencephalograph through needle electrodes inserted in both outer canthi and in the bridge of the nose. Polarities were adjusted so that movements to the right produced upward deflexions, and deviations to the left caused downward deflexions. A time-constant of 0·14 sec was used throughout. Recordings were obtained before and after each operative stage. Operations consisted in the sagittal section of the optic chiasma either prior to or following similar interruption of the corpus callosum. Serial sections of all brains, stained with Nissl and myelin sheath methods, confirmed these lesions and also showed that most of the hippocampal commissure had also been severed.

Pre-operative electro-oculograms revealed that optokinetic nystagmus to the right and to the left was symmetrical when elicited by binocular and monocular stimulation. When stimulus-figures occurred at a frequency of 1 per sec (constant angular velocity: 45° per sec) response was quite constant in each animal and varied over the group from 2 to 3 nystagmic beats per sec. Following sagittal section of the optic chiasma, electro-oculograms of optokinetic nystagmus did not differ substantially from those obtained pre-operatively. More

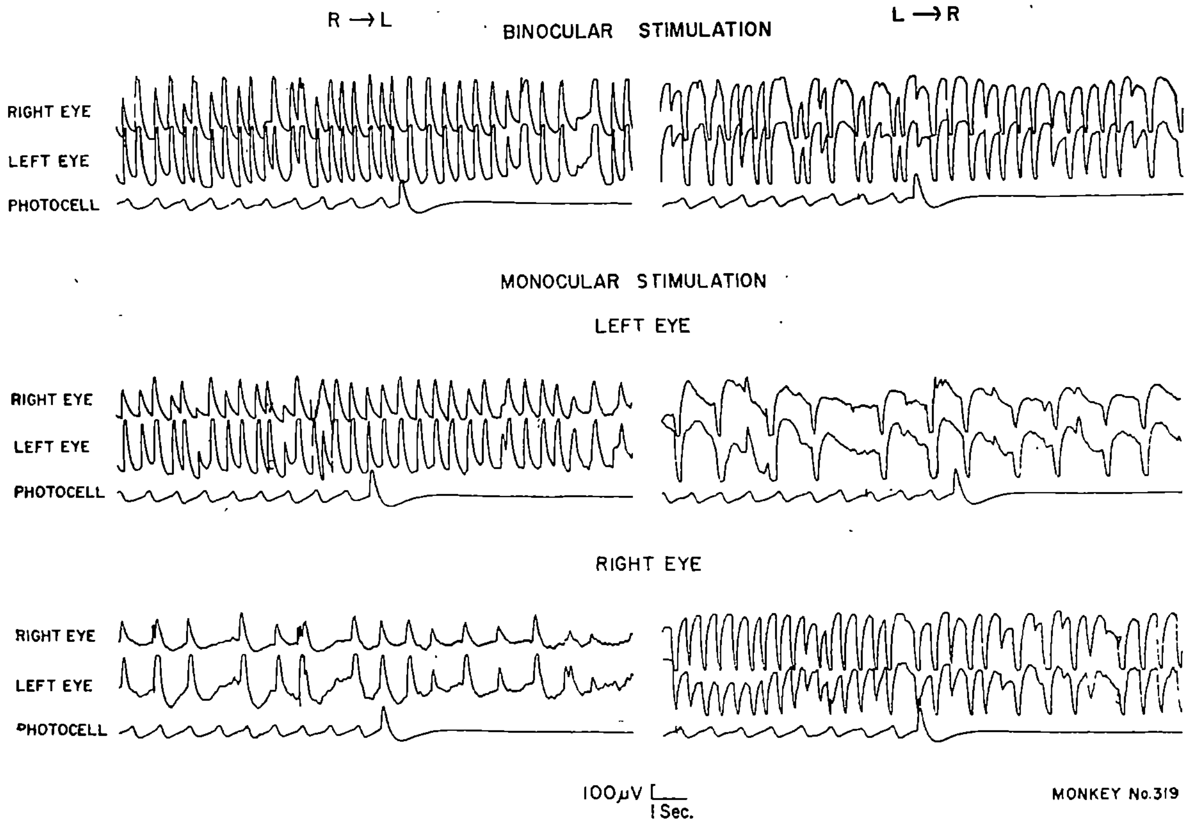

Fig. 2. Electro-oculograms of optokinetic nystagmus after section of chiasma and corpus callosum. Direction of the moving stimuli indicated by *R*→*L*, right to left, and *L*→*R*, left to right. Note the symmetry of the response elicited by binocular stimulation and the marked asymmetry under monocular stimulation. Defective nystagmus and after nystagmus occurred to the side opposite to the visually deprived hemisphere

specifically, when only the left eye was stimulated, no direct primary visual input reached the right hemisphere at a cortical or subcortical level and yet optokinetic nystagmus to the left was normal. Electro-oculograms after section of the corpus callosum in monkeys with the chiasma previously cut are found in Fig. 2. In this illustrative animal, binocular stimulation elicited a normal response with a frequency of 2·7 per sec to the right and 2·3 per sec to the left. Marked asymmetry was revealed on monocular testing. Stimulation of the left eye, that is, visual input restricted to the left hemisphere, caused a normal optokinetic nystagmus to the right, 2·4 per sec in frequency, and a slower, 1·0 per sec, nystagmus to the left. Stimulation of the right eye produced precisely the opposite effect. These recordings have been selected among those showing the least disturbance. In general, nystagmus was not only slower but also irregular, occurring in brief bursts, and at times difficult to obtain. Asymmetries were even more marked when frequency of stimulation was increased. For example, at 3 per sec stimulation (speed: 135° per sec) with both eyes open response frequency to the right and to the left was 3·3 per sec. With only the left eye open, it was 3·1 per sec to the right and 1·0 per sec to the left. These latter figures were reversed when tested with only the right eye open. It should be emphasized that in all instances the response to the same side of the stimulated eye was altered as described, but it was never altogether abolished. Section of the corpus callosum alone produced no such deficits.

These findings suggest that: (1) The first hypothesis (*vide supra*) may not be necessarily true. The response to monocular stimulation in chiasma-sectioned monkeys remained unaltered, and under those conditions, one hemisphere was totally deprived of input. Therefore, visual input to subcortical structures from the opposite field proved not to be essential for optokinetic nystagmus toward that field. (2) The second hypothesis appears to be valid. Oculomotor output for optokinetic nystagmus may be initiated in part by input to the ipsilateral hemisphere, which is conveyed through the corpus callosum to the contralateral side. The fact that some optokinetic nystagmus can still be obtained after sectioning the corpus callosum indicates that other commissural systems might play a part in this phenomenon possibly at a subcortical level.

These results are significant in two general areas of investigation: (1) The elucidation of the mechanisms for optokinetic nystagmus which we have so far discussed; (2) the problem, extensively studied by other workers, of the so-called inter-hemispheric transfer of learning. In the investigation recorded here we have a phenomenon which is not based on previous experience. The response is immediately obtained from naïve animals and man since birth as soon as stimulation starts, and it does not improve with practice. In any event, it is obvious that optokinetic nystagmus does not require any special training of the type involved in discrimination problems, and yet this unlearned response is differentially altered when elicited through one and the other eye in the chiasma-corpus callosum-sectioned monkeys. In view of these considerations, our findings raise the possibility that more elementary dysfunctions are responsible for the deficits in interhemispheric transfer after callosal section, in addition to, or maybe instead of, the postulated alteration in hypothetical mnemonic and gnosic mechanisms.

REFLEX RESPONSES IN MAN EVOKED BY GAMMA EFFERENT ACTIVATION

By JACK THORNE

Neurology Research Unit, Churchill Hospital and Lincoln College, Oxford

IN the course of observation of the late responses to peripheral nerve stimulation in the small muscles of the hand and foot, a response has been recorded from a small number of normal subjects bearing the characteristics of a reflex arising in the spinal cord from the activation of the muscle spindle fibres, via the high threshold γ-efferent fibres in the mixed peripheral nerve trunk (Fig. 1).

The response is found at stimulus amplitudes, maximal or supramaximal for the α-fibres, appearing at intensities which produce no further increment of the extrafusal fibre electromyogram (Fig. 2). The latency of the response varies from 36 to 45·5 msec, that is 10–15·5 msec longer than the labile '*F*' response[1] normally observed in these muscles.

In one subject where proximal stimulation of the nerve produced the same response (Fig. 1) the response was found to be at a longer latency, indicating the centrifugal nature of the initial component of the response. The difference in latencies over the length of nerve involved gave a figure for the conduction velocity of the γ-motor efferents in man of 45 m/sec. The constancy of the threshold of the response in relation to the maximal motor response suggests a transition of fibre diameter from the highest threshold extrafusal motor fibres to the lower threshold fibres innervating the muscle spindle.

The positive identification of the components of the mixed nerve participating in the response is not possible in man by direct access to the constituent fibres. Techniques have therefore been used to affect selectively first the fine fibres in the mixed nerve making use of the differential blocking effects of local anæsthesia[2,3], and secondly, the largest fibres which are the first to be affected by ischæmia[1]. Selective blocking of the reflex was obtained during the differential blocking phase of 'Xylocaine' anæsthesia, the anæsthetic being introduced into the forearm and hand by the technique described by Bier[4], Adams[5], and more recently by Holmes[6].

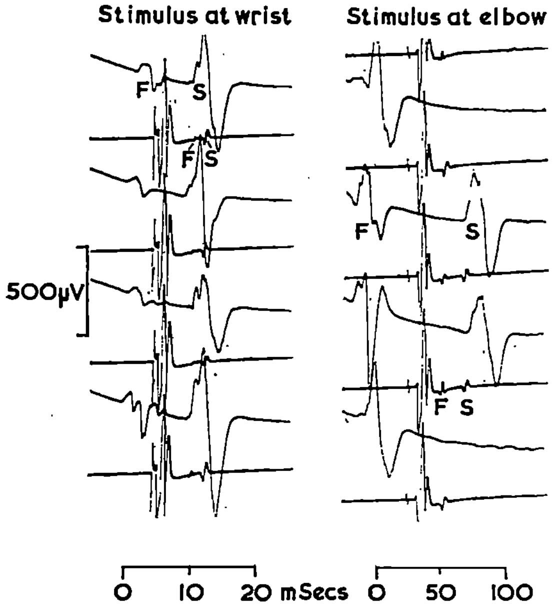

Fig. 1. Records from the first dorsal interosseus muscle showing in the expanded trace the '*F*' response followed at a constant latency by the spindle response '*S*'. With a shift of the stimulus to a more proximal point of the ulnar nerve, the '*F*' response latency is reduced while the latency of the spindle response increases

Note. The polarity of the expanded trace has been reversed.

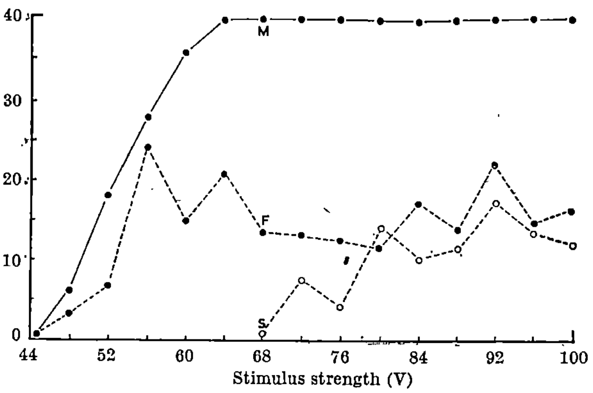

Fig. 2. The relationship between the direct motor response *M*, the '*F*' response and the spindle response '*S*'. The potentials were obtained from two bare needles inserted 2 cm apart into the muscle (first dorsal interosseus). Each point represents the mean of twenty readings. In each of the five subjects exhibiting the responses, its first appearance was made at stimulus intensities maximal or supramaximal for the alpha motor fibres

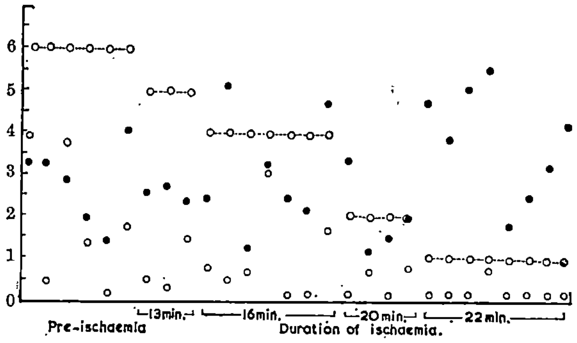

Fig. 3. Marked depression of spindle response produced by ischæmia. Response amplitude depression coincides with the fall in nerve action potential. Normal alpha motor fibres as shown by the '*F*' response. Each point the mean of ten readings

●, Response; o, spindle response; O, nerve action potential

An early depression of the response was obtained while the nerve action potential due to activity in the large 1*a* and 1*b* fibres[7] and the α-motor fibres were relatively unaffected. The depression which occurred after 3 min was not due to pressure of the cuff or ischæmia of the limb, since, as indicated in Fig. 3, which provides a control for the observation, the nerve action potential and spindle response are not attenuated for at least 10–12 min with some activity remaining after 20 min when the limb is exposed to ischæmia alone. This finding provides further evidence, in addition to the high threshold of the reflex for a fine efferent fibre component.

Interruption of the reflex pathway at the other end of the spectrum, that is, by depressing conduction in the group 1*A* spindle afferents, was obtained by occlusion of the blood supply to the forearm. Depression of the response occurs simultaneously with the attenuation of the nerve action potential while integrity of the α-fibres as evidenced by the normal '*F*' responses remains. On release of the tourniquet the return of the response coincides with the resumption of activity in the large afferent fibres, supporting the thesis that the response arises from receptors receiving an afferent supply from the large 1*A* fibres.

Exposure of the muscle to cold (immersion in iced water) produced within 5 min a marked depression of the '*S*' response. The presence of the direct motor response which although prolonged in duration by the cold was unaffected in amplitude and the persistence of the '*F*' wave indicate that the disappearance of the response was not due to failure of nerve or muscle. The sensitivity to cold is in agreement with the findings of Eldred *et al.*[8], who, working with cats, found a reduction of the response of the stretch receptors when the muscle was cooled. The beneficial effects of cryotherapy in spasticity[9] may possibly be related to this effect.

This response arising at the periphery before being attributed to activation of the intrafusal fibres of the muscle spindle must be distinguished from ephaptic activation of the sensory fibres within the terminal portion of the nerve[10,11], mechanical coupling between extrafusal fibres and the spindle[12] and other forms of sensory nerve stimulation such as that shown by Lloyd (1942) to be due to the electrical potentials produced by the depolarized muscle fibres, or antidromically conveyed sensory nerve impulses which provoke stretch receptor response[12].

With stimulation of the ulnar nerve at the wrist the response appears some 10–15 msec later than the '*F*' response. This delay is taken up by the efferent impulse travelling to the muscle and the returning afferent impulses from the muscle. Assuming an efferent delay of 5 msec at a calculated conduction velocity 45 m/sec, and an afferent latency of 3 msec, an additional interval of 2–7 msec must be accounted for. Delays of this order cannot be accounted for on the basis of an artificial synapse.

The responses in all subjects share the property of a long refractory period, varying from 20 to 100 msec. It is proposed that the conditioning volley preceding the test stimulus by an interval shorter than the rising phase of the mechanical response of the muscle unloads the spindle, rendering it insensitive to activation of the intrafusal fibres by the test stimulus. The prolongation of the refractory period in two of the subjects to 90 and 100 msec may be related to the initial muscle tension, a relationship which remains to be demonstrated. Enhancement of the response can be seen when the test response falls immediately after the rising phase of the muscle contraction. This resumption of activity at the peak of muscular contraction with, in some instances, a transient increase in spindle discharge has been observed in mammalian spindles by Hunt and Kuffler[12] and Harvey and Matthews[13]. The depression by cold, too, is unlike the behaviour of the artificial synapse where enhancement of transmission is encountered[14].

The threshold of the '*S*' response relative to the motor response excludes the explanation of this being either α-activation of the intrafusal fibres[15,16], or electrical activation of the sensory fibres arising from currents produced by muscle depolarization, or antidromic sensory impulses provoking a response from the spindle.

It is concluded that the '*S*' wave is a reflex and is obtainable, for reasons as yet obscure, in a small number of normal subjects representing evidence of a muscle spindle response to stimulation of γ-efferent fibres, which via the low-threshold spindle afferents evokes a monosynaptic response from the spinal cord. This can be recorded from the muscle as a small potential occurring at a constant latency.

A knowledge of the conduction velocity and other characteristics of the γ-efferent system in man becomes important in assessing the part which this system plays in the co-ordination or even initiation of voluntary movement in the small muscles of the hand and the extent to which this system can be incriminated in the physiopathology of Parkinson's disease and other disorders of co-ordinated muscular control.

These observations were part of a broader programme of research being carried out while I was in receipt of a research grant from the Polio Research Fund.

A THERMOELECTRIC DEVICE FOR INDUCING LOCAL TISSUE HYPOTHERMIA AND HYPERTHERMIA

By Dr. D. M. MAKOW

Radio and Electrical Engineering Division, National Research Council, Ottawa

AND

Dr. H. C. GRICE

Food and Drug Laboratories, Department of National Health and Welfare, Ottawa

The device described here was initially designed to cool and heat electronic components in a circuit[1]. The purpose of this article is to discuss its effectiveness in inducing tissue and organ hypothermia and hyperthermia.

A drawing and photograph of the heat pump are shown in Figs. 1 and 2. Two thermoelectric elements provide a positive or negative temperature difference, depending on the polarity of the current. This difference is related to the temperature of the aluminium heat sink which forms the body of the device. The outer surfaces of these elements are connected to the body, which is designed for efficient heat exchange and ease of handling. The inner surfaces make thermal contact with two inserted fittings, shaped to enclose the tissue or organ under study. Several types of fitting are provided, permitting attachment to organs of various shapes and sizes. The fittings are adjustable to allow a narrow opening so that afferent and efferent blood vessels and nerves are not interfered with. A miniature thermistor is mounted in front of the fitting, and protrudes through it, touching the enclosed organ. The temperature of the organ is then read on a meter mounted on the body.

The device is operated from a low-voltage high-current d.c. supply connected to 60-c/s, 110- or 220-V mains. In the application described here the efficiency of heating

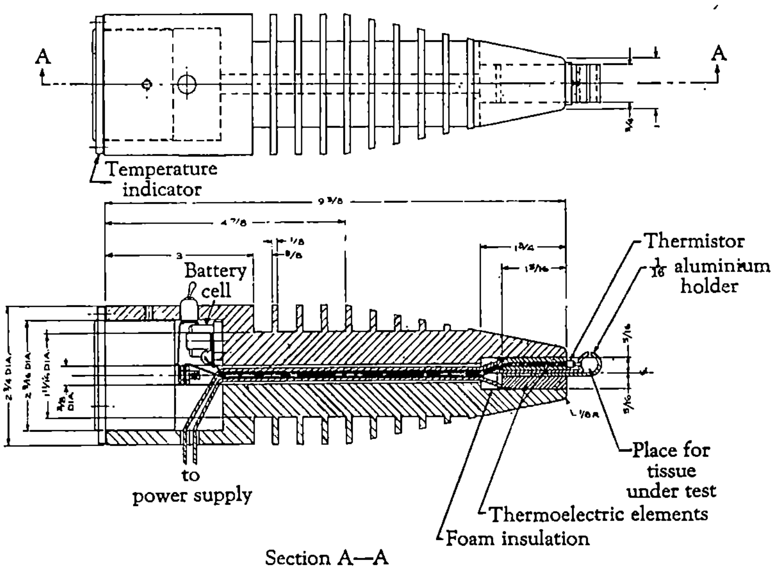

Fig. 1. Thermoelectric device for inducing local tissue hypothermia and hyperthermia: top view and cross-section

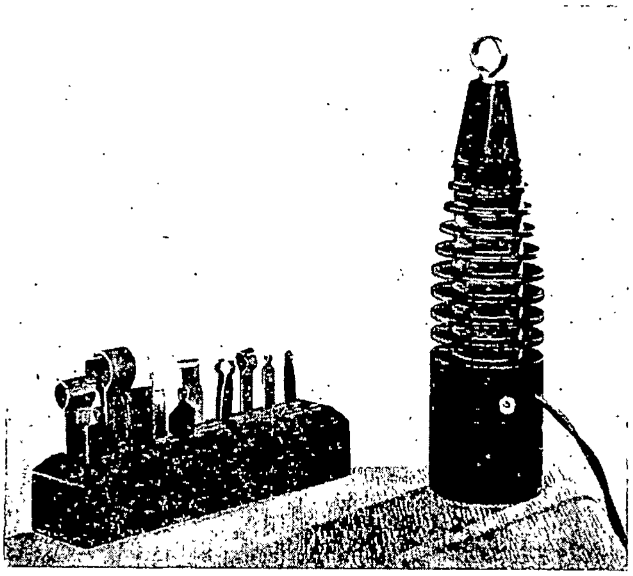

Fig. 2. Photograph of the device. An attachment best suited for the organ under investigation is chosen and inserted into the opening in the upper portion of the unit

or cooling is of no concern, as the cost of the energy consumed is negligible.

In the investigation of tissue and organ hypo- and hyper-thermia, rats were anæsthetized with pentobarbital sodium and various organs were exposed and partially enveloped by suitably shaped attachments that were inserted into the device. The tissues or organs were then subjected to cooling and heating, the degree of which was controlled by the value of the d.c. current, and the tissue temperature at the point of contact with the thermistor was read on the meter.

The lowest temperature that can be achieved is limited by the basic properties of thermoelectric elements[2] (about 65° C below ambient in vacuum with present-day elements). In an actual system the imperfect insulation of the object cooled, from environmental temperatures, reduces the above value. In particular, in the case of living tissue the vascularity of the organ influences the degree of cooling.

The highest temperature which can be achieved is only limited by the melting-point of the solder in the elements, which is about 100° C. In tissue work it must be limited by the damage threshold.

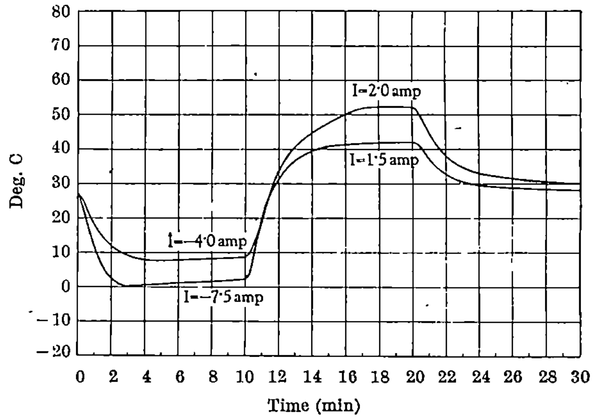

Fig. 3. Temperature of the spleen of a rat for two values of current, as a function of time

Fig. 3 shows the temperature of the spleen of a rat as a function of time, for two values of current in the cooling and heating cycle. The initial negative temperature gradient is steeper at the larger current, and the slight increase of temperature from its lowest value is due to the increase of the heat sink temperature. After 10 min the current was reversed and set to the values shown. The positive temperature gradient is here, also, a function of the current.

Lower temperatures than indicated in Fig. 3 can be achieved by reducing the temperature of the heat sink, for example, with water cooling.

Further tests were carried out on the kidney, uterus, tail, small and large intestine. In peripheral tissues, such as the tail, temperatures to −5° C and steeper gradients were observed, but the general behaviour was found to be similar to that shown in Fig. 3.

This device provides a tool for the investigation of organ function as well as its influence on the metabolism of the whole organism under carefully controlled temperature variations. Applications in therapeutic and surgical techniques are also likely.

INCORPORATION OF FALL-OUT STRONTIUM-90 IN DECIDUOUS INCISORS AND FŒTAL BONE

By Dr. HAROLD L. ROSENTHAL, SHIRLEY AUSTIN, SHEILA O'NEILL
and KUNISUKE TAKEUCHI*

Department of Physiological Chemistry

JOHN T. BIRD

Department of Dental Medicine

AND

JOHN E. GILSTER

Department of Pedodontics, School of Dentistry, Washington University, St. Louis, Missouri

IN a previous article, Rosenthal *et al.*[1] reported that deciduous incisor teeth of children born between 1953 and 1956 who were bottle-fed from birth contained only 25 per cent more strontium-90 than teeth of children who were breast-fed for an average of 25 weeks. On the basis of known ^{90}Sr/g Ca in the mother's diet and known discrimination factors, teeth from bottle-fed children were expected to contain considerably more strontium-90 than that found in the teeth from breast-fed children. Because the strontium-90 content of teeth is thought to represent the strontium-90 body burden during the time the teeth are formed, it was desirable to obtain further data on the differences in tooth strontium-90 between breast-fed and bottle-fed children in order to qualify the discrepancies between theoretical considerations and analytical observations.

Samples of non-carious deciduous incisor teeth of children born between 1950 and 1958 within a radius of 150 miles of St. Louis were pooled and analysed for strontium-90 as previously described[1]. Samples of teeth from children born during 1957 were divided into 3 groups representing teeth of children who were breast-fed for 6 months or more after birth, teeth of children breast-fed for 6 weeks to 6 months, and teeth of children who were bottle-fed from birth. In the latter group, it was deemed advisable to include samples of teeth from children who were breast-fed for less than 6 weeks because these children were probably, and intermittently, bottle-fed. The 1957 samples contained equal amounts (2 g) of tooth crown. Although teeth from the first and last six months of the birth year were analysed separately, the data were averaged for the entire yearly interval. Tooth buds and mandibles were obtained from fœtuses 7–9 months of age between 1961 and 1963. They were defleshed by boiling in distilled water, and the hard tissues from 3–5 fœtuses were pooled for each analysis.

Because analyses of ^{90}Sr content of milk in the St. Louis milk shed did not begin until 1959, the values of the Perry, New York, milk shed obtained by the New York Health and Safety Laboratories of the U.S. Atomic Energy Commission were used between 1954 and 1959. A comparison of the Perry, New York, values with the St. Louis values for 1959–63 demonstrates that St. Louis values average 1·14 times greater than Perry, New York, values. This correction has been made although these small differences do not alter the results. The milk values between 1950 and 1953 are not known and have been estimated by extrapolation of the logarithm of the milk concentration from Perry, New York, versus time for the years 1954–59 using average yearly values.

The observed values obtained for the tooth samples are shown in Table 1, and demonstrate that teeth of bottle-fed children contain 19 per cent more strontium-90 than the teeth of children who were partly breast-fed ($P = < 0.01$) and 33 per cent more than the teeth of completely breast-fed children ($P = < 0.01$). The theoretical ^{90}Sr/g Ca of teeth (C_T) was determined by expansion of the basic equation (1) developed by Reiss[2]:

$$C_T = 0.32 \text{ pre-natal } ^{90}\text{Sr/g Ca} + 0.68 \text{ post-natal } ^{90}\text{Sr/g Ca} \qquad (1)$$

The factors 0·32 and 0·68 represent the fraction of tooth calcium deposited during the pre- and post-natal periods, respectively[2]. For bottle-fed children, equation (1) becomes:

$$C_T = (0.32)\,(1.2)\,C_d^m\,D_m + 0.68\,C_d^I\,D_I \qquad (2)$$

where C_T is tooth ^{90}Sr/g Ca, C_d^m is the mother's dietary intake of ^{90}Sr/g Ca from milk and the total dietary ^{90}Sr/g Ca in the American diet is 1·2 times the amount of ^{90}Sr/g Ca found in milk[3], D_m is the discrimination factor against ^{90}Sr between the mother's dietary intake and her fœtus, C_d^I is the infant's milk intake of ^{90}Sr/g Ca and D_I is the infant's discrimination factor against ^{90}Sr between dietary intake and bone.

Table 1. STRONTIUM-90 CONTENT OF DECIDUOUS INCISORS FROM BOTTLE- AND BREAST-FED ST. LOUIS CHILDREN BORN IN 1957

	No. of samples	pc. ^{90}Sr/g Ca Found ± *S.E.*	Calc.*
Bottle-fed (> 6 weeks)	21	2·79 ± 0·08	2·53
Breast-fed (< 6 months)	12	2·19 ± 0·35	—
Breast-fed (> 6 months)	8	1·73 ± 0·33	0·52

* Calculated from equations (4) and (8). The milk concentration during 1957 averaged 4·28 pc. ^{90}Sr/g Ca.

In order to solve equation (2), values for D_m and D_I must be experimentally determined. A discrimination factor of 0·13 for D_m appears reasonable as determined from fœtal bone investigations in this report and by Reiss[2]. A value for D_I of 0·8 has been selected as an intermediate value on the basis that children under 60 days of age do not discriminate against ^{90}Sr (ref. 4) and ^{90}Sr discrimination in children under 1 year of age is probably less than 0·5 (ref. 5). Using these estimates, equation (2) may be solved to yield:

$$C_T = 0.05\,C_d^m + 0.54\,C_d^I \qquad (3)$$

Because the incisor teeth develop and calcify in less than 1 year, the ^{90}Sr/g Ca in milk (C_d^m and C_d^I) may be averaged for yearly intervals and equation (3) becomes:

$$C_T = 0.59\,C_d \qquad (4)$$

The validity of equation (4) is shown in Fig. 1, where the determined values of ^{90}Sr/g Ca in the incisor teeth of bottle-fed children born during 1950–58 are plotted against the milk nuclide concentration. The determined values compare favourably with the line drawn from equation (4).

---

* On leave of absence from Aichi Gakuin University, School of Dentistry, Nagoya.

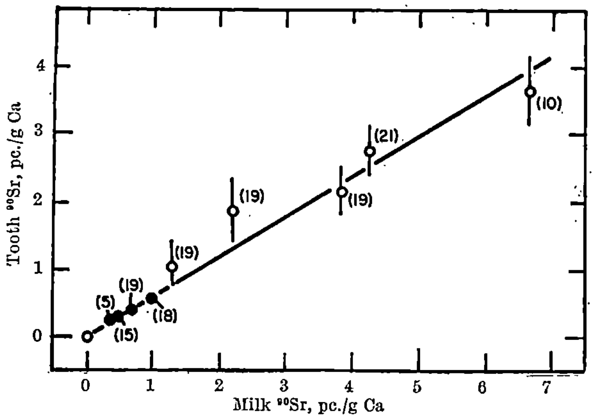

Fig. 1. The ^{90}Sr concentration of deciduous incisor teeth as a function of ^{90}Sr content of commercial milk. The number of samples analysed in parentheses. The vertical bars represent ± 1 *S.D.* The open circles represent values obtained during periods of known milk values between 1954 and 1958. The closed circles represent values obtained for estimated milk values between 1950–53. The line was drawn from equation (4).

The pre-natal contribution from the mother's diet to the fœtal teeth and bone may be defined as:

$$C_T = 1{\cdot}2\ C_d^m\ D_m \tag{5}$$

and with D_m equal to 0·13:

$$C_T = 0{\cdot}16\ C_d^m \tag{6}$$

The values for the tooth buds and bone of fœtuses between 1961 and 1963 (Table 2) demonstrate the equilibrium for ^{90}Sr/g Ca in the hard tissues of the developing fœtus, as has been previously shown[2], and the agreement between equation (6) and the determined values is satisfactory. This agreement also lends validity to the value of 0·13 for D_m, which indicates a discrimination factor of 8 against strontium-90 relative to calcium between the mother's diet and her fœtus. The value for D_m is also in agreement with the value found by Comar[6] in animals but differs from the findings of Kulp[7], who observed that the concentration of strontium-90 in fœtal bone averaged one-twelfth of that in the mother's diet.

Table 2. STRONTIUM-90 CONTENT OF FŒTAL TOOTH BUDS AND MANDIBULAR BONE*

Year	No. of samples	Tooth	Bone	Tooth; bone	Tooth and bone average	Calc.†	Deviation %
1961	6	1·82 ± 0·17	1·62 ± 0·17	1·12	1·72	1·44	−16
1962	7	1·51 ± 0·14	1·66 ± 0·22	0·91	1·58	1·76	+10
1963	17	3·39 ± 0·40	3·68 ± 0·43	0·92	3·54	3·36	−5
			Weighted average	0·96			−4

* Values expressed as pc. ^{90}Sr/g Ca ± *S.E.*

† Calculated from equation (6). Average pc. ^{90}Sr/g Ca for St. Louis milk was 9, 11 and 21 for 1961, 1962 and 1963, respectively.

For children who were completely breast-fed until after the incisor teeth were completely formed, the post-natal portion of equation (2) must be modified to include discrimination of ^{90}Sr between the mother's diet and her milk, which is approximately the same as the discrimination between the mother's diet and her fœtus, and equation (2) becomes:

$$C_T = (0{\cdot}32)\ (1{\cdot}2)\ C_d^m\ D_m + (0{\cdot}68)\ (1{\cdot}2)\ C_d^l\ D_m\ D_l \tag{7}$$

When C_d^m and C_d^l are the same, equation (7) becomes:

$$C_T = 0{\cdot}135\ C_d \tag{8}$$

Solution of equations (4) and (8) for completely bottle-fed and completely breast-fed children born in 1957 in St. Louis, as compared with the determined values, are shown in Table 1. The teeth of children who were breast-fed for less than 6 months are intermediate between completely breast-fed and completely bottle-fed children. Although equation (4) appears to be satisfactory for bottle-fed children, the determined values for breast-fed children are three-fold higher than expected when the values are calculated from equation (8).

The deviation between the theoretical and determined values for the ^{90}Sr/g Ca in the teeth of completely breast-fed children may be explained on the basis of skeletal turnover time in growing infants. Recently, Bryant[5] has reported a turn-over rate for bone of about 100 per cent during the first year after birth and, at birth, the average American infant contains 28 g of calcium in its skeleton[8]. In 1957, the fœtus would have had a skeletal burden of 0·69 pc. ^{90}Sr/g Ca (equation (6)) or a total content of 19 pc. ^{90}Sr in the hard tissues. During the first year of growth, approximately 2 g of tooth calcium are formed in all the deciduous teeth, and if no additional ^{90}Sr is obtained from the diet, a skeletal turnover of only 20 per cent would supply sufficient ^{90}Sr from the infant's own skeletal stores to account for the determined values. In addition, it is possible that the diet of completely breast-fed children was supplemented with exogenous food because the information supplied by the parents, which depends on memory, is probably inaccurate. In all probability, both factors tend to increase the tooth values of breast-fed children over that expected from equation (8). For bottle-fed children, the dietary intake of ^{90}Sr/g Ca during the post-natal period is 8 times greater than that of breast-fed children (equations (2) and (7)), and the contribution of ^{90}Sr from the bottle-fed infant's skeletal stores becomes negligible within experimental error, resulting in little or no effect on the validity of equation (4).

The peak milk concentration of ^{90}Sr occurred in June 1963, when the St. Louis milk values reached 38 pc./g calcium with a yearly average of 21 pc./g calcium. For children born during 1963, application of equation (4) yields an estimated strontium-90 burden of 12·4 pc./g of incisor calcium. The validity of this estimate must wait until 1968–70 when these teeth are shed and become available for examination.

The data presented in this report demonstrate the value of the ^{90}Sr concentration of deciduous incisor teeth as a measure of ^{90}Sr body burden and the relationship of the body burden to the dietary milk concentration for bottle-fed children at the time the teeth are formed. The difference between the values obtained for bottle-fed and breast-fed children, although statistically significant, is within the analytical errors of the estimates and does not seriously interfere with the usefulness of tooth ^{90}Sr as an index of ^{90}Sr body burden. The parameter relating the tooth ^{90}Sr to the infant's skeletal ^{90}Sr burden accumulated during the pre-natal development and the skeletal turnover during post-natal development needs to be resolved and further investigation of these phenomena is in progress.

The fœtus material was kindly supplied by Prof. Mildred Trotter, Washington University School of Medicine and the St. Louis Anatomical Board. We thank Sylvia Raymond, Sophia Goodman and Yvonne Logan for the collection of baby teeth and the Greater St. Louis Citizens' Committee for Nuclear Information for operation of the Baby Tooth Survey. The ^{90}Sr milk values for St. Louis were made available by C. M. Copley, jun., Deputy Health Commissioner of St. Louis, Mo.

Forthcoming books from Van Nostrand

Physical Electronics

G. F. ALFREY, Lecturer in Electron Physics, University of Birmingham

This text has been specifically written to introduce the physical principles governing the operation of electronic devices to first and second year electrical engineering and applied physics undergraduates. The treatment is descriptive rather than mathematical, and embraces a wealth of topics, including cathode-ray and kindred tubes, conventional and microwave thermionic valves, transistors, gas-discharge devices, semi-conductors, masers and lasers.

New Biochemical Separations

A. T. JAMES, Unilever Research Laboratory, Sharnbrook, Bedford, and
L. J. MORRIS, Unilever Research Fellow, Brunel College of Technology, London

In the past 10 years there has been a rapid advance in techniques of separation and their applications, in modified forms, to a wide variety of compounds. This reference and laboratory handbook for chemists, biochemists, clinical analysts and medical research workers presents the most up-to-date account of new and important methods for the separation of biochemical compounds. All contributors are acknowledged authorities who have themselves developed the methods they describe.

Space Vehicle Electronics

DAVID B. NEWMAN, Center for Naval Analyses, Franklin Institute, Cambridge, Mass.

The systems approach taken in this volume is that of first ascertaining requirements, environment, the nature of free-flight motion in space and the means for sensing such motion accurately and with timeliness. Communication, Radar, Guidance, Control and Power techniques are then covered from the viewpoint of systems performance in this context. Payload considerations such as operating laws, limitations, required capabilities and inter-relations with other system elements are treated. Finally, the current state-of-the-art leading to a preliminary design for the APOLLO lunar landing radar is appraised.

Matrix Analysis for Electrical Engineers

ALEXANDER von WEISS, State Academy for Applied Technology, Nuremberg

MATRIX ANALYSIS FOR ELECTRICAL ENGINEERS has been written as an introductory volume on the basic concepts of matrix analysis, a useful tool for the solution of linear problems dealing with relationships between voltages and currents. All aspects of matrix analysis relevant to electrical engineering problems are included. About one-third of the book consists of numerical examples and exercises intended to show the reader how to carry out the actual operations. Part I is on Matrices and Matrix Relations, and Part II is Selected Applications to Linear Problems in Electrical Engineering.

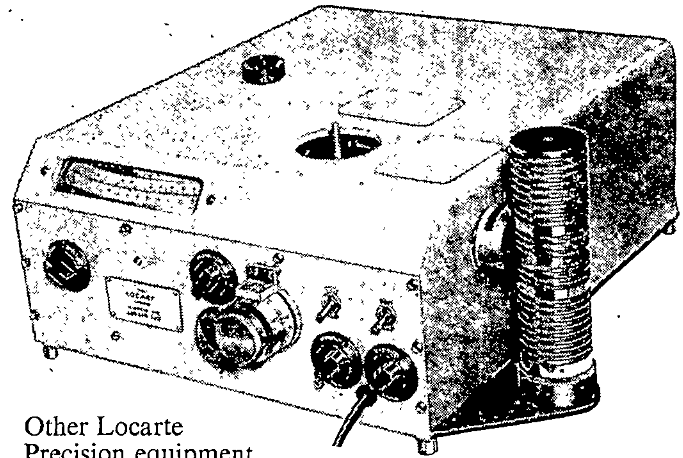
LOCARTE Fluorimeter

Excitation wavelengths commencing at 240mμ



In Laboratories throughout the world the Locarte Fluorimeter is saving time while providing unparalleled results. Important work demands precision. An extensive range of filters is available.

With an instrument so sensitive that monochromatic filter can be used on both primary and secondary sides many laboratories have extended their sphere of work. With an instrument so fast in operation your costs are reduced.

RAPID measurement of fluorescence (solution or filter paper).

SENSITIVITY : **Minimum cuvette 'blank' allows full use of 13 stage photo-multiplier and allows estimations well below .001 μg/ml. Quinine Sulphate; .0005 μg/ml. Serotonin (measuring the fluorescence in the Ultra Violet at 335 mμ.) & .1 μg of Cortisol on filter paper.**

STABILITY : **ensured by fully regulated Special Mercury or Zinc Arc Lamp.**

REPRODUCIBILITY SPEED AND ACCURACY in all your fluorometric estimations.

Other Locarte Precision equipment includes: Fraction Collectors, H.V. Electrophoresis, U.V. Handlamps, Recording Densitometers, Desalters, Column Scanners, Pipette Washers, Amino Acid Analysers.

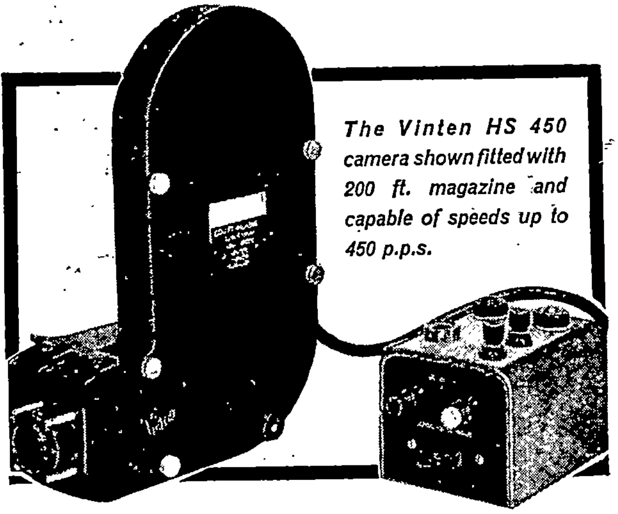
AT 450 PICTURES PER SECOND



The Vinten HS 450 camera shown fitted with 200 ft. magazine and capable of speeds up to 450 p.p.s.

The full potential of high-speed photography is only now being realised with the aid of this new series of Vinten 16 mm cameras.

These intermittent motion high-speed cameras provide speeds up to 450 p.p.s. with a remarkable advance in picture quality on anything hitherto available. 35 mm high-speed cameras are also available for speeds up to 275 p.p.s.

Information about high speed and other Vinten scientific cameras and their uses in research and industry are contained in a series of booklets available on request.

X-RAY DIFFRACTION BEGINS AT THE TARGET

The Raymax 60 X-ray diffraction unit gets the right results because targets are free from the effects of tungsten contamination. It does its work fast; it does it accurately.

The Raymax 60 has a continuously evacuated X-ray tube. This type of tube has lost none of its advantages. Based on it, Raymax 60 instruments can offer:

* pure characteristic radiation all the time. The targets can be cleaned to remove tungsten contamination which builds up in *any* X-ray tube.

* easy renewal of plug-in filaments and interchangeable targets, giving an almost infinite life, and at a fraction of the cost of sealed-off tubes.

* a stable output with modern high vacuum equipment.

* control of the focal spot size

* short camera exposure times – often half those obtainable with a sealed-off tube – with high resolution and no side band effects.

* easy maintenance and unattended working for long periods.

* a wide variety of cameras and accessories.

After-sales service for the Raymax 60 equipment is rapid and efficient. Service engineers are based in all the major cities of the United Kingdom.

FALL-OUT IN LONDON RAIN WATER

By Dr. R. WOOD, P. METSON and L. A. RICHARDS

Laboratory of the Government Chemist, Department of Scientific and Industrial Research, London, S.E.1

FOLLOWING the resumption of nuclear testing by the U.S.S.R. in September 1961, regular samples of rain-water were collected on the roof of the Laboratory of the Government Chemist, Clement's Inn Passage, Strand, W.C.2, until the end of 1963, when the Laboratory moved to Cornwall House, Stamford Street, S.E.1. These rain samples were analysed for the presence of various fission products.

The samples were collected using a polyvinyl chloride funnel, having an effective collecting area of 6 ft.². This led to a polythene collection vessel to which had been added an acidified mixed carrier solution containing known amounts of stable nitrates of each of the radionuclides to be determined. Use of this size of funnel enabled analysis to be made on samples collected from rainfalls of 5 mm and upwards. The rainfalls were calculated from the volume of rain collected and the collecting area. Up to and including April 1963, weekly or fortnightly samples were normally taken, and thereafter monthly samples. All samples of rain taken contained variable concentrations of insoluble airborne materials, partly organic and partly inorganic in character. Up to 0·2 g/l. were found, depending to some extent on the volume of sample. The inorganic constituent was mainly siliceous material along with iron and aluminium oxides. Various preliminary treatments were tried. Ultimately, it was found most advantageous to take each sample to dryness and extract the soluble salts with water. The insoluble portion was treated with hydrofluoric and perchloric acids to remove silica and oxidize the organic material. The resulting residue was dissolved in hydrochloric acid. Any residue still remaining was solubilized by means of a carbonate fusion.

Following a suitably modified version of the sequential radiochemical procedure of Osmond *et al.*[1], measurements were made of barium, cæsium, cerium and strontium radionuclides. Later, in this Laboratory, further modifications and additions were made to this sequential scheme which enabled, in addition zirconium, yttrium and rare-earth radionuclides to be determined in the same sample of rain[2]. Initially, part of the sample was examined separately for radioactive iodine nuclides. Later, separate sampling of rain-water for radioiodine assay was done, usually during and immediately after a nuclear test series. The figures for radioiodine nuclides are recorded here only when the sampling coincided with that for other nuclides. Radioiodine was determined by a procedure based on that of Glendenin and Metcalf[3], which involved a series of extractions to separate iodine from other fission products, for example, ruthenium. One of the extraction steps was replaced by a distillation step to eliminate the possibility of active particulate matter being carried between the phases in the extraction.

All the prepared sources were counted in low background anti-coincidence β-counting assemblies, the identity of each nuclide being checked by determination of the half-life when this was practicable and/or by repeating counts through specified absorbers.

Fig. 1 shows the results, plotted on a logarithmic scale, for the various radionuclides measured in London rain over the period September 1961–December 1963, inclusive. All activities have been corrected for decay to the mid-point of the collection period.

During the observation of the decay of the iodide sources it was found that the curve fell steeply for a few hours before steadying off to the characteristic decay of iodine-131 (half-life 8·05 days). This was interpreted as being due to the presence of some short-lived iodine-132 formed from its longer-lived tellurium-132 precursor, as a half-life of 2·2 h for this iodine activity was found.

$$\text{Te-132 } t^{1/2} \xrightarrow[\beta]{77\text{ h}} \text{I-132 } t^{1/2} \xrightarrow[\beta]{2\cdot2\text{ h}} \text{Xe-132 (stable)}$$

The figures for tellurium-132 shown in Fig. 1 were calculated from the activity of iodine-132 obtained by analysis of the total iodine curve.

The presence of cæsium-136 (half-life 12·9 days) in rain collected during the period September to November 1961 at the Atomic Energy Research Establishment, Harwell, has already been reported[4]. This nuclide has also been identified in rain samples collected here over the same period of time and again between August 1962 and January 1963. Its presence was first suspected when lower transmission figures than normal (50 per cent low in some cases) were obtained on counting the cæsium source through a specified absorber as a check on the identity of the 30-year half-life cæsium-137 radiation. This indicated the presence of a cæsium isotope giving a softer β-emission than that of cæsium-137, the main contributor to the activity of the cæsium sources. Counting the cæsium sources at intervals of several days gave a decay curve which was resolved to give the activities of the long-lived cæsium-137 (max.^{m} β-energy 0·5 MeV) and short-lived cæsium-136 (max.^{m} β-energy 0·34 MeV), the identity of

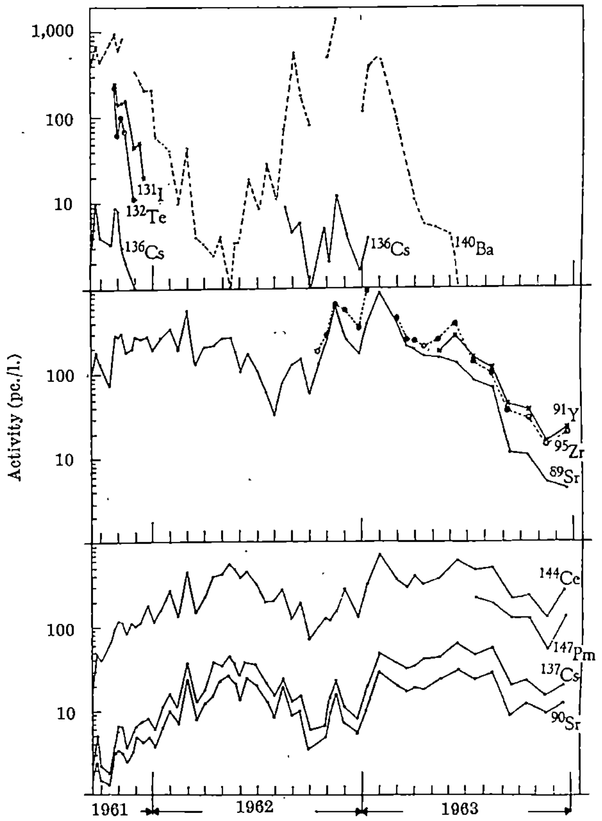

Fig. 1. Radionuclides in London rain: September 1961–December 1963

the latter being confirmed by its 12·9-day half-life. A more accurate estimate of the cæsium-137 activity was made by recounting the cæsium sources three months after the initial count, by which time the cæsium-136 had decayed away. Transmission figures in accord with the presence of cæsium-137 alone were also obtained at this time.

By means of the sequential scheme developed for this work[3] the rare-earth radionuclides were isolated as a group. However, since the determination of this group did not start until July 1963, the only rare-earth radionuclide present was promethium-147 (half-life, 2·6 years). All other fission-produced rare-earth radionuclides would have decayed by this time.

Prior to September 1961 no atmospheric nuclear tests, apart from the three small French tests in the Sahara in 1960, had been conducted since November 1958. Consequently, the only fission products in rain-water before the advent of the 1961 nuclear test series were the long-lived radionuclides such as strontium-90 (half-life, 28 years), cæsium-137 (half-life, 30 years) and cerium-144 (half-life, 285 days). Although no figures are available for the concentration of these three radionuclides in London rain before September 1961, the results obtained by the Atomic Energy Research Establishment, Harwell[5], for its levels in rain collected at Abingdon, Berkshire, in August 1961, serve as a base-line for the results in Fig. 1. These figures were 1·7 pc./l., 2·4 pc./l. and 3·2 pc./l., respectively, for strontium-90, cæsium-137 and cerium-144.

The period covered by the results in Fig. 1 includes the two nuclear test series of the U.S.S.R., that of September–November 1961 and that of August–December 1962, both series occurring almost entirely in the Arctic region. The *Dominic* test series of the United States conducted in the Pacific islands during April–July 1962 and continued in October and November of the same year also come into this period. While the Russian tests were in the main in the megaton yield range and conducted in the northern hemisphere, the American tests were mostly in the intermediate yield range (less than 1 megaton) conducted almost on the equator[6]. Consequently, the high flushes of radioactivity in London rain experienced in the autumn 1961 and again in the autumn 1962 were mainly due to tropospheric fall-out from these Russian tests.

These periods of high flushes of radioactivity were most clearly marked by the rapid increase in the concentration of the short-lived isotopes, principally barium-140 (half-life, 12·8 days) and iodine-131 (half-life, 8·05 days), in successive rain samples. With its short half-life, high-fission yield and consequent high-specific activity barium-140 is a good diagnostic of the presence of fresh fission fall-out material. In the autumn 1961 nuclear test series the level of this nuclide reached a peak of about 900 pc./l. at the end of October. With the cessation of tests the level dropped to approximately 1 pc./l. in May 1962. Thereafter, until the middle of August 1962, the levels began to rise as a result of the American tests started in April 1962, but at a much slower rate than in the autumn of 1961. The higher levels of barium-140 experienced from then on, reaching a peak of about 1,600 pc./l. towards the end of November, were due to the resumption of nuclear testing by the U.S.S.R. Since then, with no further tests taking place, the concentration of this radionuclide diminished until by mid-summer 1963 it was no longer detectable.

It was also during these periods of nuclear testing, and immediately after them, that cæsium-136 (half-life, 12·9 days) was detected. Although of comparable half-life to barium-140, the cæsium-136, a shielded nuclide, is formed in extremely low fission yield[7] and the levels of it in rain soon decayed beyond the limits of detectability.

The determination of trends in fall-out is most easily followed by the measurement of the activity of nuclides having a half-life of several years. Cæsium-137 (half-life, 30 years) and strontium-90 (half-life, 28 years) are particularly useful in this respect. Inspection of Fig. 1 shows that the concentration of these nuclides increased slowly at first in successive samples even during the initial flush of radioactivity in the autumn 1961. Then towards the end of January 1962, approximately three months after the end of the Russian test series, significant increases in the activities due to these nuclides were noted. This was an indication of the start of the annual spring rise in fall-out deposition associated with the transfer of air from the lower stratosphere to the troposphere in northern latitudes at this time of the year[8,9]. The peak of this rise of approximately 26 pc./l. and 46 pc./l. for strontium-90 and cæsium-137, respectively, was reached during May–June 1962, the time agreeing with observations made elsewhere in previous years[10]. Thereafter the levels fell despite the introduction of fresh fission products into the atmosphere from the renewed tests. A similar trend was found in 1963 towards a spring maximum, the peak activities being reached rather later than in 1962 over a period June–August with figures of approximately 33 pc./l. and 64 pc./l. for strontium-90 and cæsium-137, respectively.

It has been established by Peirson *et al.*[11] that settled conditions of fall-out do not occur for several months after the end of a nuclear test series. By this time all material originally injected into the troposphere would have been deposited and all fall-out would now be coming from the lower stratosphere. These settled conditions imply complete mixing of the new and old fission-derived material in the lower stratosphere before its gradual transfer to the troposphere and eventual deposition on the Earth's surface. One indication of this complete mixing is given when the strontium-89 : strontium-90 ratio in the fall-out decays with the half-life of strontium-89 (half-life, 51 days). This condition was first noted in rain samples collected at the end of January 1962, some three months after the cessation of weapon testing (Fig. 2) and continuing until the end of May 1962. After this time the decay of the strontium-89 : strontium-90 ratio proceeded at a slightly but significantly slower rate. This was a sign that very recent fission products, having a high strontium-89 : strontium-90 ratio, from the American nuclear tests in the Pacific (started on April 25, 1962) were now being deposited in London rain. With the recommencement of the new Russian tests on August 5, 1962, the strontium-89 : strontium-90 ratios of successive samples from September 1962 on behaved in an erratic fashion, showing a repeat of the unsettled conditions of fall-out exhibited in the autumn 1961. With cessation of tests at the end of 1962, settled conditions of fall-out appeared to have been established quickly by January 1963. Later, in July 1963, it can be seen from Fig. 2 that the strontium-89 : strontium-90 ratio had moved

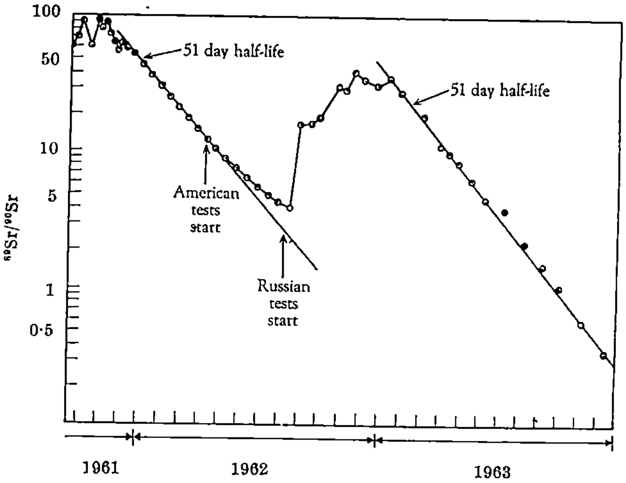

Fig. 2. Ratio strontium-89/strontium-90 in London rain water

Table 1. COMPARISON OF RADIONUCLIDES IN SAMPLES OF RAIN COLLECTED AT CORNWALL HOUSE (C.H.) AND CLEMENT'S INN (C.I.)

Period of collection 1963	Site	Rainfall (cm)	Activity pc./l. ^{89}Sr	^{90}Sr	^{91}Y	^{95}Zr	^{137}Cs	^{144}Ce
November	C.I.	9·20	5·2	9·5	16·0	14·9	16·0	127
	C.H.	9·45	4·2	8·5	18·3	14·5	15·3	131
December	C.I.	1·84	4·1	12·2	23·3	21·5	22·2	275
	C.H.	1·83	5·0	11·8	21·7	20·0	23·0	214

from the strontium-89 decay line and that in subsequent months the ratio tended to move back on to this line. This may be confirmation of the U.S. Atomic Energy Commission announcement[12] on June 30, 1963, of evidence of possible recent nuclear tests of very low yield by the U.S.S.R.

Samples collected between December 1962 and February 1963 consisted partly of rain and partly of snow. The sample collected between January 11 and February 8, 1963, was entirely of melted snow. From the higher activities found in this sample compared with the immediately preceding and subsequent samples it would appear that snow with its greater surface area : volume ratio carries down more fall-out per unit melted volume than rain. The possibility that the high activities found in this sample were due to very recent fission products not found in previous samples can be discounted since the strontium-89 : strontium-90 ratio was in line with that of preceding samples. Neither was any cæsium-136 detected, whereas this radionuclide was found in the preceding samples.

With the impending removal of the Laboratory to new quarters at the end of 1963, duplicate sampling was carried out during November and December of that year at the old and new premises. This was done to see whether any marked change in fall-out conditions existed at the new premises, since fall-out measurements would continue to be made there in the future. Table 1 lists the results obtained. Good agreement was obtained between the levels of each nuclide in the duplicate samples in each month with one exception. In December the concentration of cerium-144 in the sample taken at Clement's Inn (old premises) was 1·3 times that found in the sample at Cornwall House. A chemical re-work of each of the two cerium sources produced no change in their respective activities.

In view of reports[13] of the presence of manganese-54 in fall-out a determination[2] of this radionuclide was made in rain collected at Cornwall House in November and December 1963. Concentrations of 6·9 and 11·3 pc./l., respectively, were obtained for these monthly samples. Manganese-54 (half-life, 290 days) is not a fission product but is formed by radiative activation of material comprising the weapon casing by particles released in the nuclear burst. This radionuclide decays by electron capture followed by emission of a γ-ray, by which means it was detected and measured.

The Atomic Energy Research Establishment, Harwell, publish a detailed yearly report on radioactive fall-out in air and rain. Two such publications[5,14] report on the period mid-1961 to mid-1963 and included are results of radiochemical analyses made on rain samples collected at various sites throughout the United Kingdom. Direct comparison of these results and the London figures for fall-out concentrations in rain collected over the period under review cannot be precise since sampling periods did not coincide and the variability in rainfall and meteorological conditions must contribute to any differences noted. It was noted here that the London figures were generally higher than those of samples collected at Abingdon, near Harwell, 50 miles due west of London. The higher concentrations of fall-out in London rain were especially noticeable from October 1961 to May 1962, and to a lesser extent from November 1962 to March 1963. During a large part of both periods tropospheric conditions of fall-out prevailed. However, a more general comparison between London and the other United Kingdom sites for fall-out concentrations of strontium-89 and strontium-90 over the period under review has revealed reasonable agreement of results, the Abingdon figures being generally lower than those of the other sites, especially during 1962 (ref. 15). The only apparent peculiarity of the Abingdon site is that it is farther inland than the other sites.

At the close of the period under review, of the radionuclides determined here, the main contributions to the radioactivity in London rain, besides the long-lived strontium-90 and cæsium-137, are cerium-144 (half-life, 285 days) and promethium-147 (half-life, 2·6 years). The yttrium-91 (half-life, 57 days), zirconium-95 (half-life, 65 days) and strontium-89 (half-life, 51 days) can be expected to decay beyond the point of detectability during 1964, assuming the nuclear weapon testing moratorium continues.

We thank Dr. D. I. Coomber for his advice.

ULTRA-VIOLET ABSORPTION SPECTRUM OF THE FREE FULMINATE (C-N-O) RADICAL

By DR. W. D. McGRATH and T. MORROW

Department of Chemistry, The Queen's University of Belfast

ONE of the first known examples of isomerism was that shown by the cyanates or isocyanates *R*—OCN and *R*—NCO, and the fulminates *R*—CNO. In the cyanate or isocyanate free radical (NCO) the carbon atom occupies the central position, whereas in the fulminate (CNO) this central position is filled by the nitrogen atom. The ultra-violet spectrum of the free NCO radical has recently been obtained in absorption by Holland, Style, Dixon and Ramsay[1] and shown to consist of two distinct systems due to the transitions $A(^2\Sigma^+) - X(^2\Pi_i)$ and $B(^2\Pi_i) - X(^2\Pi_i)$; the system due to the former lying in the region of 4400 Å and the latter occurring between 2650 Å and

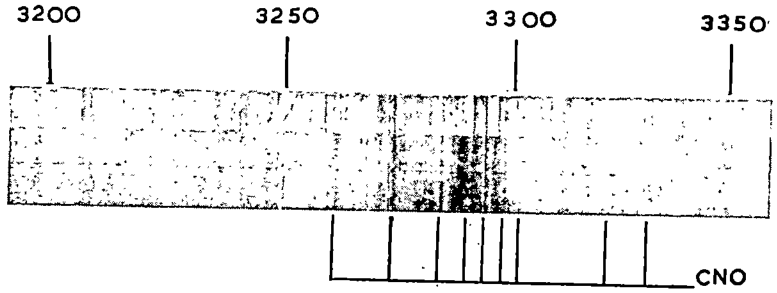

Fig. 1. Absorption spectrum of the fulminate radical taken 15 μsec after flashing a cyanogen/ozone/argon mixture of ratio 5 : 1 : 50. Flash energy, 1,280 J. Pressure of mixture used, 3·5 cm mercury

3200 Å. From a detailed analysis of the $\Sigma - \Pi$ bands Dixon[2] concluded that the NCO radical is linear in both ground and excited states.

We have recently observed these same two systems of NCO in absorption, using the technique of flash photolysis and kinetic spectroscopy, in the investigation of reactions involving oxygen atoms and cyanogen. Together with the NCO bands a new complex system, which has been attributed to the fulminate radical, was observed in the wave-length region 3250–3330 Å. The strongest and best-resolved spectrum of the radical was obtained by flashing a mixture of cyanogen and ozone using excess argon as inert diluent in a conventional flash photolysis apparatus in which the flash tube and reaction vessel were constructed of ordinary transparent quartz and lay side by side in a cylindrical reflector. The type of apparatus used has been fully described by McGarvey and McGrath[3]. Fig. 1 shows the spectrum obtained at a short delay time after flashing such a mixture, and Table 1 lists the wave-lengths of the band heads together with their relative intensities.

When a cyanogen/argon mixture was flashed under similar conditions to those used in the case of cyanogen/ozone/argon mixtures no CN absorption could be detected, and since this radical is a strong absorber the amount of direct photolytic decomposition must be extremely small under these conditions. The effect of the photolytic flash was therefore confined to the dissociation of the ozone in these experiments. From the work of McGrath and Norrish[4] it is known that ozone decomposes under these conditions as follows:

$$O_3 \xrightarrow{h\nu} O_2 + O(^1D) \tag{1}$$

In the absence of any competitive reaction for the removal of oxygen atoms reaction (1) is followed by the fast reaction (2), resulting in the production of vibrationally excited oxygen molecules.

$$O(^1D) + O_3 \rightarrow O_2{}^* + O_2 \tag{2}$$

When the cyanogen and ozone were present in equimolecular amounts in the cyanogen/ozone/argon mixtures, used in these experiments, vibrationally excited oxygen molecules with v'' up to 17 were produced by reaction (2) and easily detected at short delay times by means of the strong Schumann–Runge absorption system. When the cyanogen/ozone ratio was increased to 5 : 1 this spectrum due to excited oxygen molecules disappeared, indicating the preferential removal of $O(^1D)$ by some reaction involving cyanogen molecules. However, from the absorption spectra obtained at short delay times after photolysing both the foregoing mixtures it was possible to identify the two systems of NCO along with extremely strong CN absorption and the system attributed to the free CNO radical.

All these observations indicate conclusively that the $O(^1D)$ removal reaction involving the cyanogen molecule is as follows:

$$O(^1D) + N \equiv C{-}C \equiv N \rightarrow CNO + CN \tag{3}$$

The $O(^3P)$ ground-state oxygen atom also seems to react according to equation (3), since when nitrogen dioxide was used as the atomic oxygen source absorption spectra taken at short delay times (15 μsec) after flashing again showed the band system 3250–3330 Å attributed to the CNO radical. Attack by an oxygen atom on cyanogen is most likely to produce CNO, but it is possible that NCO could also be produced to a small extent in this way. The principal reactions for the production of NCO must undoubtedly be:

$$CN + O_3 \rightarrow NCO + O_2 \tag{4}$$

$$CN + O_2 \rightarrow NCO + O \tag{5}$$

and it would seem equally likely that reactions (4) and (5) could also result in the formation of the fulminate radical as in equations 6 and 7:

$$CN + O_3 \rightarrow CNO + O_2 \tag{6}$$

$$CN + O_2 \rightarrow CNO + O \tag{7}$$

To provide additional evidence for the assignment of the 3250–3330 Å bands to the free CNO radical reactions (5) and (7) were investigated. In order to carry out these experiments, it was necessary to modify the equipment in such a way as to overcome the weak absorption characteristics of cyanogen and give a reasonable photolytic decomposition into CN radicals on flashing. This was accomplished by combining flash tube and reaction vessel in a condenser-like arrangement in which the flash occurred in the annular space between the inner reaction vessel and the outer quartz envelope. The outer quartz envelope was covered with aluminium foil in order to concentrate the light into the reaction vessel, which was made of spectrosil. With this high-efficiency annular type of flash tube it was possible to dissociate a considerable amount of cyanogen with flash energies of about 1,200 J. Absorption spectra, taken at short time-intervals after flashing the cyanogen/oxygen/argon mixtures of ratio 1 : 1 : 15, showed the presence of NCO and CNO, in accordance with what one would expect from reactions (5), (7) and (8).

$$(CN)_2 + O(^3P \text{ or } ^1D) \rightarrow CNO + CN \tag{8}$$

Another interesting feature of these experiments was that while a cyanogen/argon mixture would show very strong CN radical absorption on flashing, an equivalent mixture in which cyanogen and oxygen were present in equimolar amounts showed no trace of the CN radical even at the shortest delay time used (15 µsec). This complete suppression of the CN absorption by oxygen is indicative of the extreme speed of either one or both of reactions (5) and (7). Of these two reactions (7) must be the more favoured since when oxygen is present even in extremely small concentration the CNO bands at 3250–3330 Å can be detected whereas the NCO absorption does not appear. Indeed, if great care is not taken to remove oxygen from the cyanogen and inert gas these CNO bands appear strongly.

In order to confirm the assignment of the 3250–3330 Å bands to the CNO radical it was decided to investigate the isothermal flash photolysis of gaseous fulminic acid. The gaseous fulminic acid was prepared by reacting formamide oxime (NH_2—CH=N—OH) with an excess of slightly moist hydrogen chloride gas in a sealed tube. The formamide oxime was heated slightly (about 50° C) to initiate reaction and the fulminic acid obtained was diluted with a large excess of argon.

The absorption spectrum obtained at 15 µsec after flashing a 1 : 10 fulminic acid/argon mixture showed the same 3250–3330 Å bands obtained in the previous experiments. The only reasonable primary photolytic process occurring here would be:

$$\text{H—C—N—O} \xrightarrow{h\nu} \text{H} + \text{CNO} \qquad (9)$$

thus providing additional confirmation that these 3250–3330 Å bands are due to the free CNO radical.

A similar series of bands in the same spectral region as those of CNO reported here have been detected in emission from flames supported by active nitrogen by Jennings and Linnett[5]. Unfortunately these authors did not give any figures for the wave-lengths of the band heads and since their published spectrum was a print of a plate taken on a medium quartz spectrograph a direct comparison with the bands reported here could not be made. Jennings and Linnett attributed their bands to an emitter containing only carbon and nitrogen and so concluded that the most likely species were C_2N, CN_2 or some excited state of cyanogen. Of these three possibilities the most likely one to occur during the initial attack of oxygen atoms on cyanogen would be C_2N, produced according to reaction (10).

$$(CN)_2 + O \rightarrow C_2N + NO \qquad (10)$$

If this reaction occurs it would seem equally likely that atomic species other than oxygen, for example, sulphur or chlorine, would also lead to the formation of the C_2N radical. In order to test this possibility an investigation was made of the isothermal flash photolysis of cyanogen/carbonyl sulphide, cyanogen/carbon disulphide and cyanogen/halogen mixtures. The band system in question, that is, the complex system 3250–3330 Å, was not observed during any of these experiments although in the case of the carbonyl sulphide/cyanogen mixtures the sulphur atom seemed to follow a somewhat similar behaviour to the oxygen atom in that the absorption spectrum of the free NCS radical was observed 15 µsec after the photolytic flash.

Since the fulminate radical seems to be very reactive (lifetime not more than 50 µsec) it would seem likely that it plays an active part in the cyanogen/oxygen and cyanogen/ozone flames. The extreme reactivity of this radical especially with oxygen can be deduced from the fact that an increase in the proportion of oxygen in the cyanogen–oxygen mixtures results in the suppression of the CNO spectrum. In order to obtain more relevant information on the participation of this radical in combustion processes its subsequent reactions are at present undergoing a more detailed investigation.

POSSIBLE STRUCTURES RELATED TO GMELINITE

By GEORGE T. KOKOTAILO

Research Department, Socony Mobil Oil Co., Inc., Paulsboro, New Jersey

AND

STEPHEN L. LAWTON

Department of Chemistry, Iowa State University, Ames, Iowa

IT is well known that closest-packed structures containing spheres of equal radii form hexagonal layered structures. Such structures are often described by means of the symbols *A*, *B* and *C* for the three possible layers of close-packed spheres differing from one another in position[1–3]. Alternatively, the same stacking of layers is sometimes designated by the symbols *h* and *c*, as suggested by Pauling[1], in which the symbol *h* applies to a layer in which the two neighbouring layers are of the same type (that is, both *A*, both *B* or both *C*) and the symbol *c* in which the two neighbouring layers are of different types (for example, layer *B* in contact with the layers *A* and *C*).

There are numerous sequences in which close-packed layers may be stacked. Thus, the smallest possible value of n in a close packing, where n is the number of layers required to complete the sequence, is 2, corresponding to the hexagonal closest packing with an . . . *AB* . . . arrangement. In a like manner, the only possible sequence for $n = 3$ is the cubic closest packing with . . . *ABC* . . . When $n = 4$ the only possible hexagonal closest-packing arrangement is . . . *ABAC* . . . and when $n = 5$ it is . . . *ABCAB* . . . For $n = 6$ it is now possible to arrange the layers in two ways, namely, . . . *ABCACB* . . . and . . . *ABACAB* . . . As pointed out by Smith[2] and Wells[3], beyond $n = 6$ as n increases the number of arrangements of close-packed layers also increases. Only the structures with $n \lesseqgtr 6$ are discussed here. Each structure is hexagonal (except for . . . *ABC* . . . with $n = 3$, which is cubic). The lattice parameter a_0 remains unchanged; only c_0 varies by integral multiples.

It is now shown that such nomenclature may be applied with remarkable success in the classification of the zeolites of the chabazite group. In this class the hexagonal prisms (double six-membered rings) may be considered as the building blocks. Each zeolite differs from the other by the stacking sequence of the various layers, the full symmetry of which depends on the number and arrangement

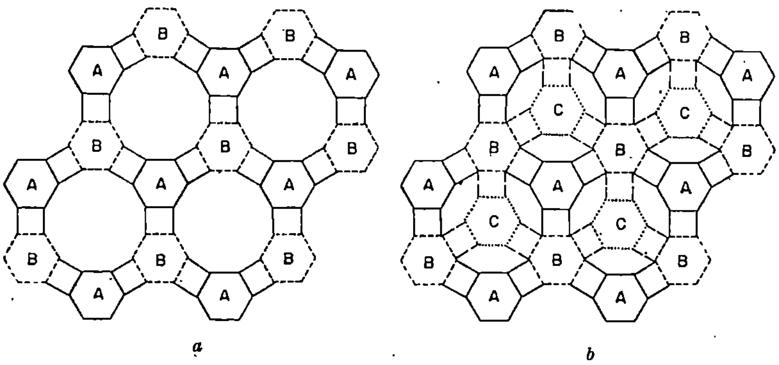

Fig. 1. 001 projections. Each hexagonal ring represents a double six-membered (Si, Al) ring. (*a*) *AB* layer as in gmelinite; (*b*) *ABC* layer arrangement

of layers necessary to complete the stacking sequence. Twenty possible structures in addition to the . . . *AB* . . . (. . . *hh* . . .) and . . . *ABC* . . . (. . . *ccc* . . .) structures for spheres of equal radii are listed by Wells[3]. Theoretically, all twenty could be applied to possible zeolites by replacing each sphere with a double (or single) six-membered ring stacked parallel to the *c*-axis of the hexagonal cells.

Structure of gmelinite, chabazite and erionite. Gmelinite is hexagonal[4] with average lattice parameters $a_0 = 13{\cdot}7_4$ Å and $c_0 = 10{\cdot}0_4$ Å. The (Si, Al)-O framework is formed by joining double six-membered rings through their edges. As is shown in Fig. 1*a*, these prisms form planes stacked parallel to each other and perpendicular to the *c*-axis with an . . . *ABAB* . . . sequence. The gmelinite cavity possesses $3/m$ symmetry and is formed out of the sequence (*ABA*). Since the repeating sequence is . . . *AB* . . . the *c*-dimension of one sequence (layer) is one-half the c_0 parameter, or 5·0 Å.

Chabazite is rhombohedral[4–6]. The (Si, Al)-O framework is formed through an . . . *ABC* . . . sequence with the same type of layers found in gmelinite. Since such an arrangement is cubic for spheres of equal radii, the deviation from cubic symmetry to rhombohedral symmetry is thus expected since, the building blocks are not spherical. Alternatively it is, of course, also possible to describe chabazite with a hexagonal cell with average lattice parameters $a_0 = 13{\cdot}7_5$ Å and $c_0 = 15{\cdot}0_0$ Å (refs. 4–6). Chabazite is thus related to gmelinite by a very simple relationship: in the *c*-direction each set of two layers has been rotated 60° in the same direction about the *c*-axis running through the centre of a double six-membered ring. Thus, . . . *AB*,*AB*,*AB*, . . . of gmelinite becomes . . . *AB*,*CA*,*BC*, . . ., or simply . . . *ABC*,*ABC*, . . . Repetition in the *c*-direction has been increased by one more plane of double six-membered rings; this adds 5·0 Å to the c_0 lattice parameter to yield a theoretical parameter of 15·0 Å, which is 3/2 the c_0 parameter of gmelinite. This is found to be in close agreement with the experimental value.

The . . . *ABC* . . . sequence is shown in Fig. 1*b*. The twelve-membered ring channels of gmelinite are now blocked; strongly suggesting that it is this type of blocking which reduces the sorptive properties of gmelinite. It also strongly suggests that a chabazite sequence would have very little difficulty growing on to a gmelinite sequence, since no change in energy is expected in forming sequence *AB* rather than *AC*.

The structure of erionite has also been reported as being hexagonal[4–6]. It may be described as having an . . . *ABCB* . . . sequence with $n = 4$. Whereas both gmelinite and chabazite contain just double six-membered rings, erionite is considered to have single as well as double six-membered rings periodically linked together. Corresponding, then, to the foregoing nomenclature layers, *A* and *C* consist of the single six-membered rings and *B* the double six-membered rings. The second type of nomenclature suggested by Pauling now becomes very useful and is even more informative. Here the . . . *ABCB* . . . sequence corresponds to . . . *hc* . . . Thus, in erionite we find that the *h* layers correspond to the single and the *c* layers to the double six-membered rings.

Two new proposed structures. In considering the build-up of possible structures containing just double six-membered rings, a new cavity may be formed which is similar to the erionite cavity. Such a cavity is formed when $n = 4$ for the . . . *ABCB* . . . sequence and $n = 6$ for the . . . *ABCACB* . . . sequence. For want of a better name, these two new structures will be called hypothetical structure I and II, respectively, and will be referred to as I and II.

In the structure of I, formed by the . . . *ABCB* . . . sequence with $n = 4$, the large cavities (*ABCBA*) lie along the *c*-direction of the hexagonal unit cell, one above the other and joined through double six-membered rings (rather than through single six-membered rings as in erionite itself). Each cavity has nine non-planar eight-membered ring openings as shown in Fig. 2*c*. The three openings in the top and the three in the bottom half are each shared by other I cavities which are displaced along the *c*-direction by one-half the unit cell-length; the three central eight-membered ring openings are each shared with a gmelinite cavity. Thus, each I cavity is surrounded by six other I cavities and by three gmelinite cavities. The c_0 lattice parameter is theoretically 20·0 Å; a_0, of course, remains unchanged.

Hypothetical structure II, formed by the . . . *ABCACB* . . . sequence with $n = 6$, contains the same large cavity as in I; however, in this structure the chabazite cavity is also present so that now all three cavities—gmelinite, chabazite and I—co-exist, resulting in a hexagonal unit cell the c_0 parameter of which is now 30·0 Å. The framework of these cavities is shown in Fig. 2. This structure may also be described by again considering the cavities which

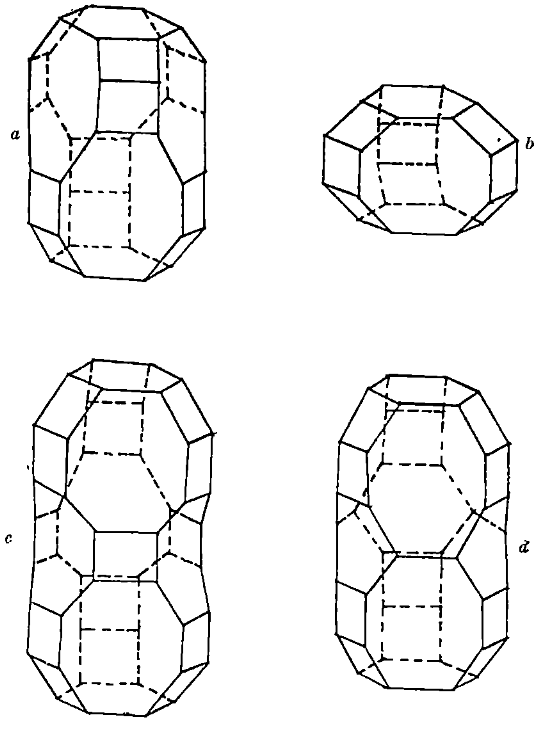

Fig. 2. The cages in (*a*) chabazite, (*b*) gmelinite, (*c*) hypothetical I and II, (*d*) erionite. The aluminium and silicon atoms occupy the corners. The oxygen atoms and cations are not shown

Table 1

Name	No. of layers in repeating unit	Layer sequence	Layer sequence, Pauling notation	*h*	*c*	Length of *c*-axis*
Gmelinite	2	...*AB*...	...*h*...	Double	—	10·0 Å
Chabazite	3	...*ABC*...	...*c*...	—	Double	15·0
Erionite	4	...*ABCB*...	...*hc*...	Single	Double	15·1
Hypothetical structure I	4	...*ABCB*...	...*hc*...	Double	Double	(20·0)
Hypothetical structure II	6	...*ABCACB*...	...*hcc*...	Double	Double	(30·0)

* Experimental values from ref. 4. Theoretical values are indicated in brackets.

are attached to the I cavity: attached to the top three and bottom three eight-membered ring openings are the chabazite cavities, the top three being inverted with respect to the bottom three in accord with the 3/*m* symmetry; the three central eight-membered ring openings are each shared with a gmelinite cavity, which accounts for the additional 10·0 Å in the c_0 lattice parameter relative to that for the I structure.

A summary of the zeolites discussed here is given in Table 1, which includes a summary of those layers consisting of single and double six-membered rings.

In view of the nomenclature discussed here, the similarities in structure of gmelinite, chabazite and erionite are evident. The fact that gmelinite has sluggish sorption and that the sorptive properties are similar to those of the other members of the chabazite group may be qualitatively explained in terms of random or periodic blocking of the twelve-membered ring channels by a layer turned 60° to form an *ABC*, *ABCB* or *ABCACB* sequence. Thus, if the chances of growth of *B* on *A* and *C* on *A* are about equal, it appears that intergrowth of chabazite, gmelinite, I and II would be possible. Finally, in view of the theoretically possible periodic stacking of *A*, *B* and *C* it is evident that many other structures might be possible, consisting of a stacking of planes of single, double or single and double six-membered rings.

We thank Dr. W. M. Meier for his advice.

CONTAINMENT OF PLASMA IN A MAGNETIC MIRROR, WITH HEXAPOLE STABILIZING FIELDS

By G. FRANCIS, D. W. MASON and J. W. HILL

Culham Laboratory, U.K. Atomic Energy Authority, Abingdon, Berkshire

IN the experiments reported here, plasma of density approximately 4 × 10^{10} ions/cm^3 and mean ion energy 1 keV trapped in a magnetic mirror has been found to escape by a rotating flute instability within 60–80 μsec. When hexapole cusp-like fields perpendicular to the mirror field were added, the flute instability disappeared and the density of trapped plasma decayed smoothly with a time constant which could be as large as 400 μsec. Some plasma was observed in the magnetic trap after 1 msec.

A hydrogen plasma was produced by a coaxial gun[1] (peak current of 44 k.amp, rising in 1 μsec) and its properties measured in a uniform guide fields of 600 oersteds at a point 2 m from the gun. The plasma consisted of a fast component of density 3 × 10^{11}/cm^3, mean directed velocity 4·5 × 10^7 cm/sec (corresponding to an ion energy of 1 keV), perpendicular energy 60 eV, electron temperature about 12 eV; followed by a much denser and slower component ($n \sim 3 \times 10^{12}$/cm^2, velocity $\sim 10^6$ cm/sec). The measurements were made with diamagnetic loops, ion collectors, biased Langmuir probes and a special electrostatic ion-energy analyser. The ions in the fast plasma were H$^+$.

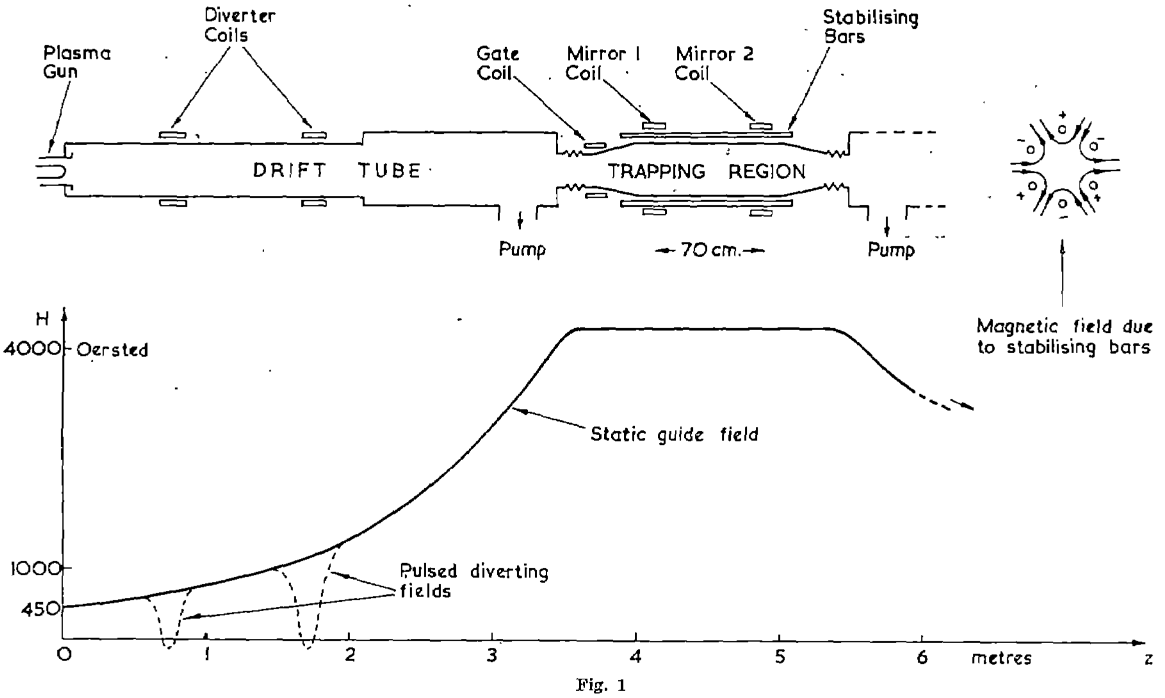

Fig. 1

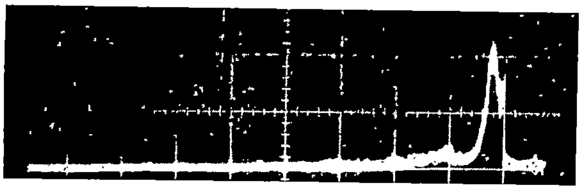
In the containment experiments the plasma from this gun was injected into a static converging magnetic field which increased smoothly from 450 œ to 4·3 kœ over 3·5 m length, remained uniform over a further distance of 2 m (the central trapping region) and beyond that decreased symmetrically to 450 œ (Fig. 1). The fast plasma moved adiabatically along this field from the gun into the central trapping region. The slow plasma was prevented from following it by the sudden application of pulsed magnetic fields opposite to the guide field, at points 75 cm and 170 cm from the gun. This diverted the slow plasma into the walls of the vessel, which was of 22-cm diameter 'Pyrex' glass in the central section and under the diverter coils, and of 31-cm diameter aluminium elsewhere. The base pressure was 3×10^{-7} torr. Pulsed magnetic fields were produced by the coils marked mirror 1, 2, and 'gate' on the diagram: the mirror coils superimposed on the d.c. guide field an additional 3·6 kœ rising in 50 μsec and decaying with a time-constant of 4·5 msec; the gate coil produced 13 kœ rising in 12 μsec, decaying in 50 μsec. Plasma was trapped by first energizing mirror 2, firing the gun and then applying the gate and mirror 1 fields before the reflected plasma could escape. This produced a simple symmetrical magnetic mirror trap of ratio initially 1·8, changing by about 10 per cent within 1 msec.

The density of the trapped plasma, measured with a 3 cm microwave interferometer, had a mean value of $4 \times 10^{10}/cm^3$ over a diameter of 10 cm. The lifetime of the fast ions was obtained by measuring the flux of fast atoms formed by charge exchange on the background gas: the neutral atom detector incorporated a water-vapour cell in which about 6 per cent of the fast atom flux was converted back into ions by charge exchange, and the flux in a given energy interval was measured. Fig. 2 shows a typical result; the fast ions (of energy 1·6 ± 0·2 keV) escaped from the magnetic mirror in less than 80 μsec. Measurements with double Langmuir probes (1 cm^2 area) arranged around the circumference of the vessel showed that the plasma was rotating at 10^5 radians/sec and also moving radially outwards with an average velocity of 5×10^5 cm/sec (Fig. 3). Signals on probes disposed parallel to the lines of force were highly correlated. High impedance electrostatic probes inserted into the plasma indicated fluctuating electric fields (~ 30 V/cm) consistent with the speed and direction of rotation.



⟵ *t* 100 μsec/cm

Fig. 2. Simple mirror configuration

In subsequent experiments, cusp fields perpendicular to the axis of the vessel were pulsed on at the same time as the mirror 1 and gate fields. The cusp fields were produced by six groups of bars 140 cm long lying parallel to the axis and disposed symmetrically around the central part of the vessel at a radius of about 15 cm. Currents in adjacent groups flow in opposite directions (Fig. 1). The field rose to 11 kœ between bars in 45 μsec and fell by 25 per cent in 1 msec. In this magnetic configuration the flux of neutral atoms decayed smoothly with a time-constant of several hundred microseconds (Fig. 4). The density could not be measured with the microwave interferometer due to the complexity of the magnetic field, but the flux of neutral atoms was the same as in a simple mirror, indicating a comparable density. No rotation or spiralling of the plasma was observed: wall probes along the cusp lines showed a smooth signal for a few hundred microseconds, but other wall probes showed no signal. The electric field in the plasma was less than 1 V/cm.

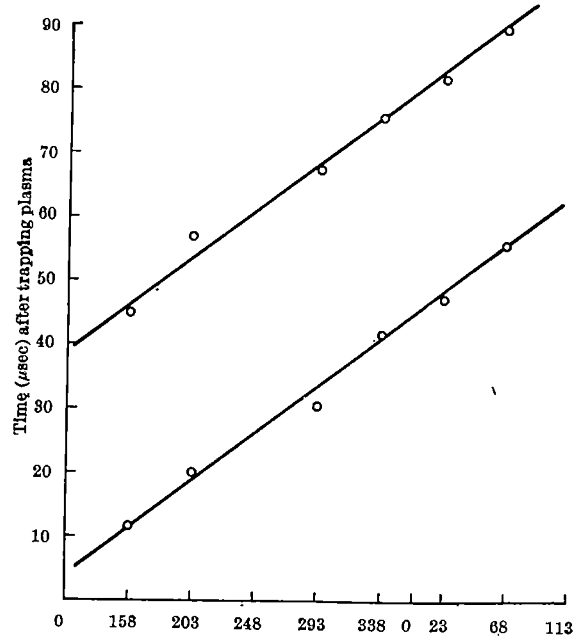


Fig. 3. Time of peak Langmuir probe signal versus azimuthal probe position for circumferential array of eight probes

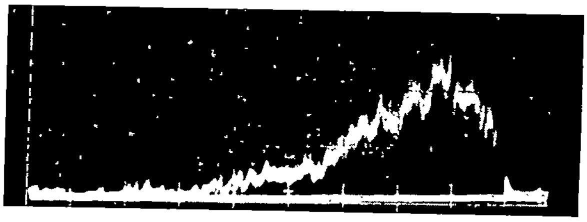

⟵ *t* 100 μsec/cm

Fig. 4. Mirror-cusp configuration

The decay of the plasma, although smooth, was some four times faster than would be expected from charge exchange on the background gas at the measured base pressure. We believe that the neutral gas density is suddenly increased by gas knocked off the walls due to plasma bombardment observed during the trapping process, a belief supported by mass spectrometer analysis. Moreover, when the amount of injected plasma was reduced by a limiter with a small hole, the decay time of the trapped plasma increased from about 250 to 400 μsec: also, when the diverting fields were not used, the fast plasma disappeared abruptly when the slow plasma arrived. Thus, the residual plasma-loss rate observed with the hexapole fields excited is qualitatively consistent with a charge exchange mechanism.

These results are consistent with those of Ioffe[2] *et al.*, who first used this type of magnetic field configuration but with a different method of plasma generation. They show the advantages of combining the stabilizing properties of cusp fields with the adiabatic confinement due to simple magnetic mirrors, as pointed out by Artsimovich[3] and examined theoretically by Taylor[4].

We thank Mr. K. Plummer and Mr. A. Ellington, who made the apparatus, and Mr. D. Wort, Dr. M. Seidl and Mr. E. Hotston, who made the microwave measurements.

LETTERS TO THE EDITOR

ASTROPHYSICS

Stability of Hydrogen Compounds on Venus

Recent space probe measurements have confirmed that high-temperature conditions prevail in the lower atmosphere of Venus[1]. Since high temperatures favour the establishment of thermochemical equilibria, these observations require a revaluation of physical and chemical conditions on this planet. I have proposed large-scale interaction of the atmospheric gases and the minerals of the lithosphere to account for the observed atmospheric characteristics[2], and it was demonstrated that the carbon dioxide content of the atmosphere can be accounted for by decarbonation reactions at the inferred temperature of 700° K. In addition, it was proposed that the failure to observe hydrogen compounds is consistent with the expected high rate of escape of hydrogen and the comparatively high oxidation state of the atmosphere.

Unsuccessful attempts to detect CH_4, C_2H_6, C_2H_4 and NH_3 in the atmosphere of Venus were made by Kuiper[3], and recently Spinrad[4] has concluded that the mixing ratio of water is less than 10^{-5} at depths in the atmosphere corresponding to a total pressure of 8 atmospheres. It therefore seems likely that this mixing ratio limit holds to the base of the atmosphere.

The stability of the hydrogen compounds on Venus may be related to the observable parameters $(P_{\mathrm{CO_2}}/P_{\mathrm{CO}})$ and $P_{\mathrm{H_2O}}$ (so far determined as limits only), where the P's refer to the fugacities or partial pressures, depending on the deviation from perfect mixtures. From Kuiper's results[3] we obtain $(P_{\mathrm{CO_2}}/P_{\mathrm{CO}}) \geq 10^3$ if the absorption paths for carbon dioxide and carbon monoxide in the Venus atmosphere are comparable and if the fugacity ratios are roughly proportional to the abundance ratios. Also according to Sagan[5] it seems likely that the total surface pressure is in the range of 10–100 atmospheres. If P(total) $\sim$ 100 atmospheres, then the water mixing ratio limit of 10^{-5} gives $P_{\mathrm{H_2O}} \leq 10^{-3}$ atmospheres at the surface. Thus the atmosphere is very dry at the inferred temperature of 700° K. It is obvious that lower values of P(total) yield even smaller values of $P_{\mathrm{H_2O}}$.

We may now calculate the surface hydrogen pressure limit from the limits of $(P_{\mathrm{CO_2}}/P_{\mathrm{CO}})$ and $P_{\mathrm{H_2O}}$ by the following reaction:

$$CO_2 + H_2 \rightleftharpoons CO + H_2O \qquad (a)$$

This reaction has the equation of equilibrium:

$$\frac{P_{\mathrm{CO_2}}}{P_{\mathrm{CO}}} K_a = \frac{P_{\mathrm{H_2O}}}{P_{\mathrm{H_2}}} \qquad (1)$$

where $K_a = 10^{-0.95}$ at 700° K, from the data of Rossini *et al.*[6]. Accordingly we obtained $P_{\mathrm{H_2}} \leq 10^{-5.05}$ at the surface.

From the foregoing data it is in principle possible to evaluate the stabilities of many hydrogen compounds. For example, it is interesting to examine Hoyle's speculation[7] that large quantities of hydrocarbons may occur on Venus. We may begin by examining the stability of methane, the most stable member of the paraffin series. The pertinent reaction is:

$$2\,H_2 + 2\,CO \rightleftharpoons CO_2 + CH_4 \qquad (b)$$

and the corresponding equation of equilibrium is:

$$\frac{P_{\mathrm{CO}}^2}{P_{\mathrm{CO_2}}} K_b = \frac{P_{\mathrm{CH_4}}}{P_{\mathrm{H_2}}^2} \qquad (2)$$

At 700° K we obtain from the data of Rossini[6] that $K_b = 10^{4.52}$, and if $(P_{\mathrm{CO^2}}/P_{\mathrm{CO}}) \geq 10^3$, $P_{\mathrm{CO_2}} \sim$ atmospheres[2], and $P_{\mathrm{H_2}} \leq 10^{-5.05}$, then $P_{\mathrm{CH_4}} \leq 10^{-10.58}$ atmospheres at the surface. Thus reaction (*b*) is displaced to the left by both the strongly oxidizing conditions and the low hydrogen partial pressure.

We may now also evaluate the stabilities of the higher polymers of the paraffin series by relating them to the hydrogen and methane abundances. For example, for *n*-octane we have the following reaction:

$$8\,CH_4 \rightleftharpoons C_8H_{18} + 7\,H_2 \qquad (c)$$

The equilibrium constant[6] for this reaction is $K_c = 10^{-33.2}$, which shows that this polymer cannot be abundant. Similarly all the higher polymers will be less abundant than methane since the free energies of formation increase by a constant increment of 11,951 calories per CH_2 group at 700° K.

From these tables of free energies of formation we may also compare the relative stabilities of the various hydrocarbon series. It is obvious that such comparisons can be made only when all the gases are in some standard state since the stabilities depend on the gas pressures. We may, for example, compare ethyl*cyclo*hexane with *n*-octane:

$$C_8H_{18} \rightleftharpoons C_8H_{16} + H_2 \qquad (d)$$

ΔG^0 at 700° K for this reaction is 470 calories. The low hydrogen partial pressure that is required to make $(P_{\mathrm{C_8H_{16}}}/P_{\mathrm{C_8H_{18}}})$ large ensures the instability of the hydrocarbons.

The benzene series of hydrocarbons is somewhat more stable than the paraffin series for corresponding polymers under standard conditions. However, the lowest benzene polymer is C_6H_6, and this will be far less abundant than methane. Thus it seems unlikely that any significant quantities of hydrocarbons could occur on the surface or in the lower atmosphere, and this seems also to preclude their occurrence in the higher atmospheric levels.

Most other hydrogen compounds also seem precluded by the Venus environment. For example, we may consider the stability of the ammonia molecule according to the reaction:

$$\tfrac{1}{2}\,N_2 + 3/2H_2 \rightleftharpoons NH_3 \qquad (e)$$

From the data of Kubaschewski and Evans[8] and of Kelley[9] we see that $K_e = 10^{-1.21}$. Thus if $P_{\mathrm{H_2}} \leq 10^{-5.05}$ we obtain the result that:

$$P_{\mathrm{NH_3}} \leq 10^{-1.21}\,(10^{-5.05})^{3/2}\,P_{\mathrm{N_2}}{}^{\frac{1}{2}} \qquad (3)$$

showing that no significant quantity of ammonia can occur if $P_{\mathrm{N_2}}$ has any reasonable value for a terrestrial planet of this size.

No attempt is made here to evaluate the stabilities of other more complex hydrogen-bearing gaseous molecules. However, it is apparent that none of these hydrogen compounds will be favoured in any absolute sense by the high temperatures and low hydrogen partial pressure.

A problem of considerable interest concerns the condensed hydrogen compounds in the lithosphere of Venus and their relation to the atmospheric gases. The stabilities of certain hydrous rock-forming silicates have already been discussed by me[2]. The problem is a difficult one since only a limited number of experimental data exist. However, it seems that the limiting value of $P_{\mathrm{H_2O}} \leq 10^{-3}$ atmospheres at the surface is somewhat below the stability range of at least some hydrous silicates. Thus the thermochemical data obtained by Weeks[10] and by Robie[11] indicate that the $P_{\mathrm{H_2O}}$ required to stabilize the amphibole tremolite with respect to the pyroxenes and free silica is 0·04 atmospheres. However, it seems probable that more stable hydrous silicates than this exist, with complex Mg–Al-bearing amphiboles and micas being the likely species.

The recent suggestion by Walter[12] regarding the possible occurrence of hydrous carbonatite magmas on the Venus surface is certainly in conflict with the cited data of Spinrad on the abundance of water. Such magmas appear to require water partial pressures in the range of ten atmospheres under the most favourable conditions, which as we have seen are four orders of magnitude greater than the deduced limiting value. Also if hydrogen has long been escaping from Venus, as we have reason to believe, then the lithosphere should be depleted of water except for that bound tightly in the silicates. Thus even the existence of hydrous magmas within the crust seems unlikely.

It is apparent that the conditions deduced for the lower atmosphere of Venus militate against the occurrence of life if it consists of the usual hydrogen, carbon and nitrogen compounds. It is remotely possible that some form of life could exist under æolian conditions in the middle atmosphere where the temperature is lower. However, it seems very improbable that such life forms could survive for long under the expected vicissitudes.

Since hydrogen escapes from Venus, we should expect considerable differences in the secular behaviour of the hydrogen compounds as compared with other species. Thus, although the concentrations of oxygen, carbon dioxide and carbon monoxide might be approximately fixed for long periods by the buffering effect of the condensed lithospheric minerals[2], we should expect that the secular depletion of hydrogen would prevent long-term buffer relations with respect to water. The extent to which such differences would show up depends on the rate of the photochemical decomposition of the hydrogen compounds and the escape rate of hydrogen.

Slowly Varying Component of Solar Radio Emission in Relation to the Solar Cycle

IN a previous communication we showed[1] that the so-called slowly varying component (*S*-component) of solar radio emission, exhibiting the characteristic 27-day variation in the received flux, is limited only within the frequency range 470–29,000 Mc/s and that the amplitude of the characteristic variation would be maximum at a frequency over 4,000 Mc/s. However, the foregoing analysis was performed with the help of solar radio noise flux data for the International Geophysical Year period of 1·5 years only, that is, during the period when the Sun was in the most active form in the present solar cycle. It is quite logical to examine the data over a longer period with a view to seeing whether the above conclusions made for the *S*-component are also valid year to year throughout the solar cycle. We were thus prompted to study the slowly varying component of solar radio emission in relation to solar cycle.

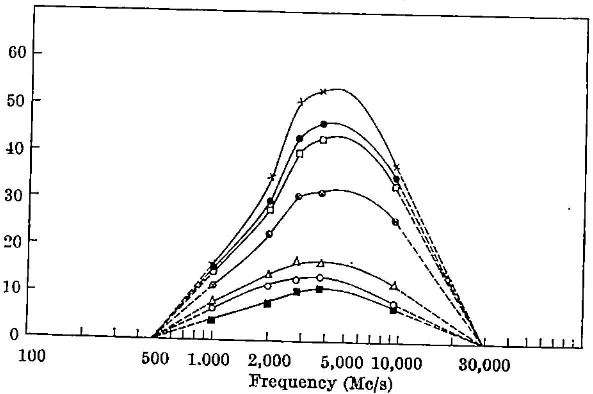

Fig. 1. The curves showing the relation of the variation index with frequency for the years 1957 (×), 1958 (●), 1959 (□), 1960 (⊗), 1961 (△), 1962 (○) and 1963 (■)

The method of analysis adopted in the present case is similar to the earlier one referred to above. In that analysis plots of the daily mean values of solar flux at five different frequencies (9,400, 3,750, 2,800, 2,000 and 1,000 Mc/s) for the International Geophysical Year period were examined. All these plots exhibited pronounced maxima and minima following roughly the 27-day cycle and it was also observed that the amplitude of this variation changed markedly with frequency. A variation index (V.I.) was defined for a particular frequency as the variation of the amplitude from a maximum to the corresponding minimum, showing the characteristic periodicity, averaged over the entire period. Besides the conclusions mentioned here it was also shown that the variation index might conveniently be used as a measure of the correlation between the slowly varying component and the sunspot activity. The present analysis has been carried out for all the above five frequencies over the period 1957–63. For any particular frequency the variation index has been determined individually for every year by the same procedure.

Fig. 1 shows the plot of the variation index against frequency for different years. It is found that all the seven curves are similar and are of the same nature as was previously obtained by us. Moreover, when extrapolated, the continuous curves through the different sets of points would intersect the frequency axis at the same regions—470 Mc/s in the low-frequency side and 29,000 Mc/s in the high-frequency side. It is also observed that the variation index appears to be maximum

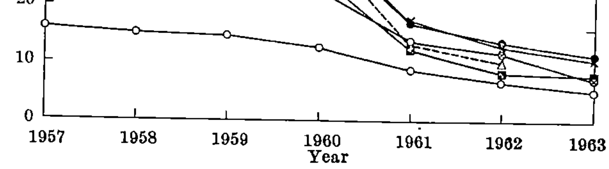

Fig. 2. Plots showing the year to year change in the variation index for the frequencies 9,400 Mc/s (■), 3,750 Mc/s (●), 2,800 Mc/s (×), 2,000 Mc/s (⊗) and 1,000 Mc/s (○). The figure also shows the corresponding variation of the yearly mean Zurich relative sunspot numbers △

in general in the frequency range 4,000–5,000 Mc/s. The results thus obtained for all the seven years confirm, to a large extent, the conclusions of our previous analysis both regarding the cut-off frequencies of the *S*-component of the solar radio emission and also the frequency at which the so-called variation index attains a maximum value. It will be interesting to note here that the curves shown in Fig. 1 are of similar nature to those obtained by Kakinuma and Swarup[2] for the spectra of the *S*-component.

An additional striking feature exhibited by the curves of Fig. 1 is that as we proceed from 1957 onwards the curves gradually come down, indicating a fall in the value of V.I. from year to year. This led us to examine the matter in some detail. Fig. 2 shows the plot of the variation index against year with frequency as the parameter. The yearly mean values of Zurich relative sunspot number are also shown on the same diagram. It will be found that the year to year values of the variation index for all the frequencies show parallelism with those of the sunspot numbers, which clearly indicates the solar cycle dependence of the slowly varying component. The factor by which the index changes from the maximum value in 1957 to the minimum in 1963 are shown in Table 1.

Table 1

Frequency in Mc/s	9,400	3,750	2,800	2,000	1,000
$\frac{\text{V.I. in 1957}}{\text{V.I. in 1963}}$	4·7	4·3	4·8	4·6	3·8

The fact that the variation index depends on the solar cycle led us to examine its variation with sunspot number (Fig. 3). A linear relation is obtained for the two quantities. It is interesting to find that the straight line when extrapolated to zero sunspot number cuts the index axis with a positive intercept which implies that the variation index is not zero, but something positive, though small, even at zero sunspot number condition when the Sun should be completely quiet. The intercepts between the values 5 and 7·5 involve variation of the order of 10–15 flux units.

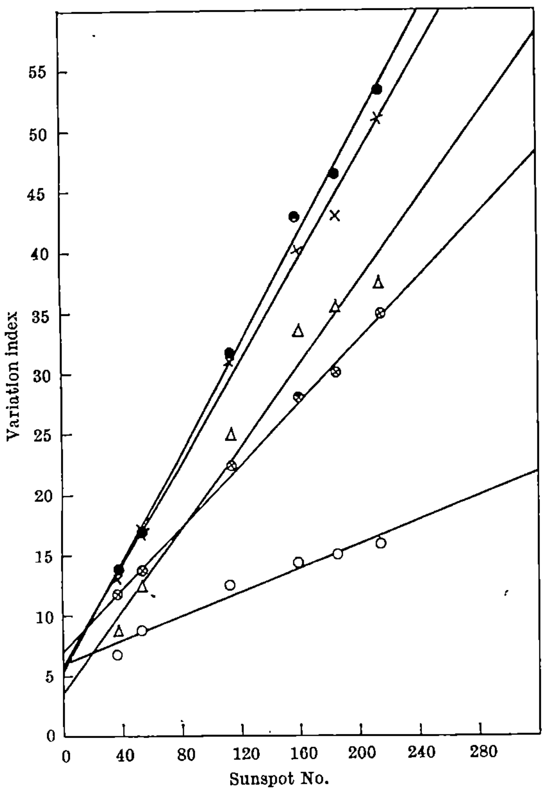

Fig. 3. Plots showing the linear relation between the variation index at frequencies 9,400 Mc/s (△), 3,750 Mc/s (●), 2,800 Mc/s (×), 2,000 Mc/s (⊗) and 1,000 Mc/s (○) and the yearly mean Zurich relative sunspot numbers for the period 1957–62

The foregoing analysis leads us to draw the following conclusions:

(1) The *S*-component of solar radio emission is to be observed only within the frequency range 470–29,000 Mc/s, maximum variation being limited in general in the frequency range 4,000–5,000 Mc/s (Fig. 1). The fact that this is true all throughout the solar cycle is highly significant and needs special attention. It may thus be concluded that the origin of the *S*-component is restricted within two distinct levels of the solar atmosphere and also the maximum variation will occur within a specified zone all throughout the solar cycle.

(2) The *S*-component varies in accordance with the solar cycle (Fig. 2). The factor by which its value changes from the year of maximum activity to that of minimum is slightly over 4. It may be mentioned here that Nicolet[3] also indicated a figure of the same order from a different consideration.

(3) Finally, the slowly varying component is linearly related to the sunspot number. The fact that the component exists even when the sunspot number is zero (Fig. 3) needs further investigation. Possibly this may be due to some active regions on the solar disk with no associated sunspot as have been detected by Covington and Harvey[4].

It should, however, be clearly indicated that the important conclusions drawn here regarding the slowly varying component in relation to solar cycle depend solely on the true nature of the curves shown in Fig. 1. It is thus apparent that in order to evaluate the two cut-off frequencies as well as the frequency at which the variation index becomes maximum more precisely one must consider the individual cases of as many frequencies as possible, particularly in the frequency ranges 500–2,000 Mc/s and 10,000–30,000 Mc/s.

We thank Prof. J. N. Bhar for his advice. One of us (D. B.) thanks the Council for Scientific and Industrial Research, Government of India, for financial assistance. Results used in our analysis were obtained from *CRPL–Solar Geophysical Data Books* and IGY, IGC and post-IGC results published by the Science Council of Japan. We also thank Dr. H. Tanaka of the Research Institute of Atmospherics, Nagoya University, Japan, for sending us some of his solar radio noise data before publication.

GEOPHYSICS

Instability of Temperature Ice-sheets owing to a Feed-back Mechanism

THE response of a temperate glacier to changes in its specific budget was theoretically examined in 1903 by S. Finsterwalder[1]. He limited himself to the plane problem, and I shall do the same. In 1958 Weertman[2] urged forward the problem by introducing the perturbation method and the incidence of the changes in the superficial slope.

For the calculations, the firn is changed into an equivalent ice-sheet of compact ice. The x axis is taken along the surface in the direction of flow. Let $q_0(x)$, $h_0(x)$ and $\alpha_0(x)$ be the datum-state values of the discharge per unit breadth, the thickness of the ice-sheet and the slope of its surface, respectively. Let $q_1(x, t)$, $h_1(x, t)$ and $\alpha_1(x, t)$ be the per-

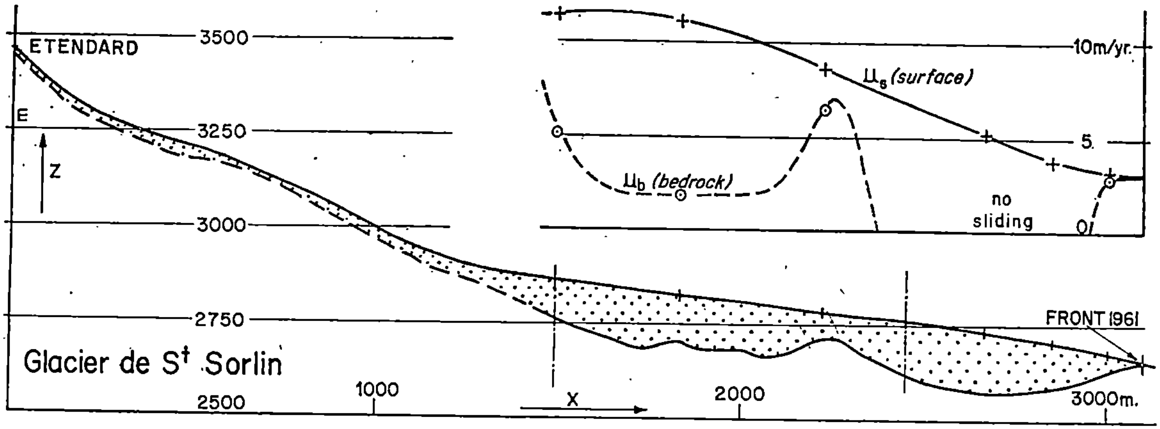

Fig. 1

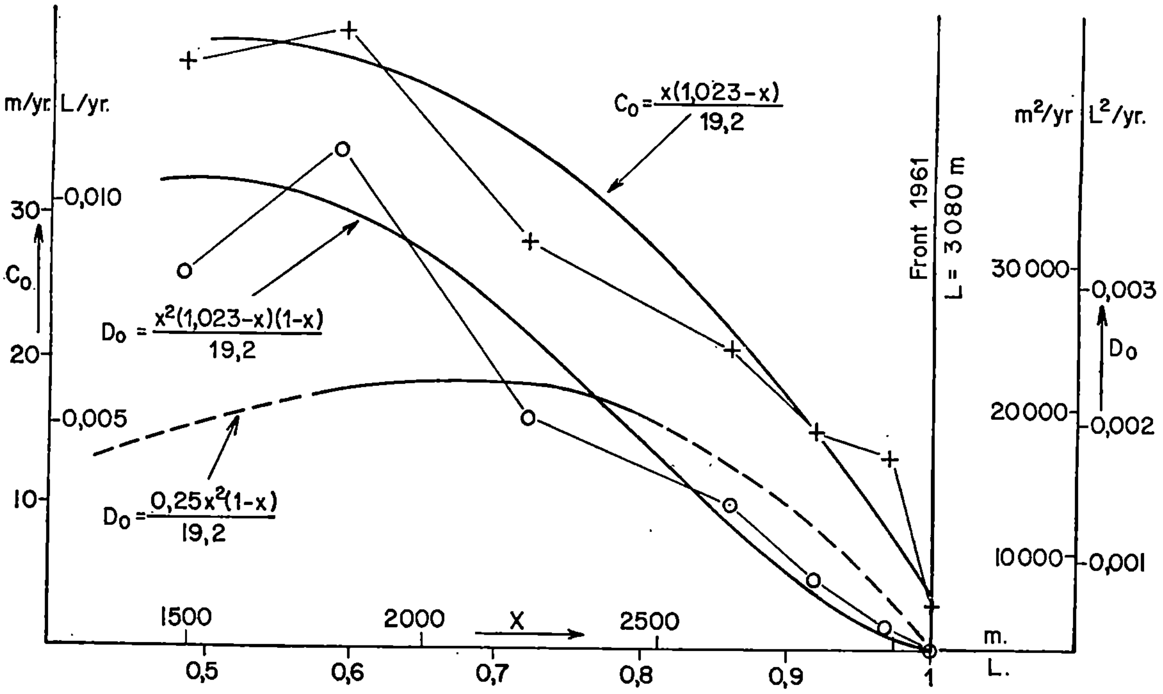

Fig. 2

turbations of these variables. We call b the specific budget (snowfall + superimposed ice-ablation, in height of ice per unit time). b_0 is not the datum-state value, but the value at which the glacier would have been in a steady state at $t = 0$:

$$b_0(x) = \frac{dq_0}{dx}$$

The response of the glacier to a slight change in the specific budget, say, $b_1(x, t)$, is given by the continuity equation. I shall write it as did Nye[3]:

$$\frac{\partial h_1}{\partial t} = b_1 - c_0' h_1 - (C_0 - D_0') \frac{\partial h_1}{\partial t} + D_0 \frac{\partial^2 h_1}{\partial x^2}$$

with:

$$C_0(x) = \left(\frac{\partial q}{\partial h}\right)_0 \qquad D_0(x) = \left(\frac{\partial q}{\partial \alpha}\right)_0$$

Nye has given a very interesting algebraic model. Taking the length of the glacier as the unit of length, let us write it in a slightly different manner:

$$C_0 = \frac{x(1 + \delta - x)}{T} \qquad D_0 = \frac{E x^2(1 - x)}{T}$$

δ, T and E are constants ($\delta \ll 1$). Nye solved the perturbation equation when b_1 is independent of x and $E = 1$. In fact, whenever E is the reciprocal of an integer p, a closed solution can be written. First let b_1 be a step function:

$$b_1 = 0 \qquad t < 0$$
$$b_1 = A \qquad t \geqslant 0$$

Let:

$$h_1 = H_0 + H_1 x + \ldots + H_n x^n + \ldots$$

writing $t/T = \tau$ and:

$$(n + 1)(1 + \delta - nE) = r_n$$
$$[n + 1][1 - (n - 1)E] = s_n$$

one gets the equations:

$$\frac{dH_n}{d\tau} + r_n H_n = s_n H_{n-1}$$

Whence:

$$\left(\frac{d}{d\tau} + r_0\right)\left(\frac{d}{d\tau} + r_1\right)\ldots\left(\frac{d}{d\tau} + r_n\right)H_n = s_1 \ldots s_n AT$$

So H_n cancels when $n > p$. Deriving the solution for a step function we obtain the response of the glacier to an impulse unity at $t = 0$:

$$R(x, t) = \dot{H}_0 + \dot{H}_1 x + \ldots + \dot{H}_p x^p$$

with, for $t \geqslant 0$:

$$\dot{H}_n(t) = s_1 \ldots s_n \left[\frac{e^{-r_0 t/T}}{(r_1 - r_0) \ldots (r_n - r_0)} + \ldots + \frac{e^{-r_n t/T}}{(r_0 - r_n) \ldots (r_{n-1} - r_n)} \right]$$

The damping coefficients r_n are bigger than unity, the last one, $r_p = (p + 1)\delta$, excepted.

The response to any variation $b_1(t)$ is then:

$$h_1(x, t) = \int_{-\infty}^{t} b_1(\theta) \,.\, R(x, t - \theta) \,.\, d\theta = \int_{-\infty}^{+\infty} (\text{the same})$$

As in any filter, the complex amplification (H/A in Nye's paper) is the Fourier transform of $R(x, t)$.

Let us see now if Nye's algebraic model is a realistic one. According to the theory of parallel flow for temperate glaciers and Weertman's theory of sliding, we can approximately write, n being the power in the deformation law of ice, $m = (n + 1)/2$, and C_1 and C_2 two constants:

$$q = C_1 h^{n+2} \alpha^n + C_2 h^{m+1} \alpha^m$$

The measured velocity on the surface is:

$$u_s = \frac{n + 2}{n + 1} C_1 h^{n+1} \alpha^n + C_2 h^m \alpha^m$$

and the less-accurately known sliding velocity on the rock bed:

$$u_b = C_2 h^m \alpha^m$$

Whence, taking the commonly accepted value $n = 3$:

$$C_0 = 4 u_s - u_b$$

$$D_0 = [2 \cdot 4 \, u_s + 0 \cdot 6 \, u_b] \frac{h_0}{\alpha_0}$$

(Nye's statement $u_s \simeq u_b$ cannot be accepted, as Weertman's theory is only valid for very slow sliding velocities[4].)

A longitudinal cross-section of the Glacier de Saint-Sorlin according to seismic soundings[5], the measured values of $u_s(x)$ and the estimated values of $u_b(x)$ are given in Fig. 1. The corresponding values of C_0 and D_0 are given in Fig. 2. By taking $T = 19 \cdot 2$ years and $\delta = 0 \cdot 023$, C_0 fits the algebraic model well. But no value of E can make D_0 fit the model. In fact, it has been proved[6] that E must be equal to 1 near the begschrund and near the front. However, for the ablation zone of the Glacier de Saint-Sorlin, Nye's model can be kept with $E = 0 \cdot 23 \simeq 1/4$ more or less.

Wegmann and Cailleux have noted that the thickening of an ice sheet affords an increase in the specific budget at a given point. This feed-back mechanism can be accounted for by writing:

$$b = b_0(x) + M h_1 + b_1(t)$$

In the ablation zone, for an alpine glacier, $M \simeq 0 \cdot 01$ yr.$^{-1}$. The expression of $R(x, t)$ remains unchanged, but the damping coefficients become:

$$r_n = (n + 1)(1 + \delta - nE) - MT$$

The last one:

$$r_p = (p + 1)\delta - MT \simeq -0 \cdot 1$$

becomes negative. So Nye's algebraic model of a glacier is an unstable one. This conclusion is still effective if we consider b_1 dependent of x, for example, $A = A_0 + A_1 x + A_2 x^2$, as only the first three H_n are changed.

This instability of glacier snouts seems to be real, and may be found with an even more realistic function for D_0. An active ice sheet cannot end on a level bed-rock with a stable edge-shaped snout. It must advance or recede until it reaches some special area. This can be a step of the valley, where the velocity x is increased, and thus δ. It can also be a lake, where the glacier end floats, and then the altitude of its surface becomes about eight times less dependent on glacier thickness, and so also M.

Thus temperate ice sheets fluctuate within areas of stability, and from time to time recede or advance from one area of stability to another. This illuminates the behaviour of glaciers. It explains the formation of recessional moraines during the last stage of the ice-age.

Seismic Anisotropy of the Uppermost Mantle under Oceans

OLIVINE in rock-forming aggregates has a strong tendency during flow or deformation to develop a preferred orientation of its crystallographic axes. Turner[1] describes a number of olivine fabrics developed under a variety of conditions. The pertinent examples, his figures numbers 7, 10 and 13, show fabrics for banded dunites in which the *b* crystallographic axis is strongly concentrated perpendicular to the banding, and figure 16, in which *b* is perpendicular to a plane of pronounced fissility. The (010) plane of olivine is the plane of the best cleavage and most probable glide plane for this mineral.

Verma[2], working in Francis Birch's laboratory, determined the seismic velocities for olivine as shown in Fig. 1. If the upper mantle has been subjected to flow in the horizontal plane and this has resulted in even a slight statistical orientation of one or more of the olivine crystallographic axes, the differences in seismic velocities are so great that it should be evident in velocities found by seismic refraction (see also Hess[3] and de Roever[4]). The concept was tested against fourteen seismic refraction profiles for an area straddling the Mendocino fracture zone presented in a paper by R. Raitt[5] at the I.U.G.G. meeting at Berkeley in August 1963 (Fig. 2). All profiles which gave both the seismic velocity below the Moho and the azimuth on which they were observed were used with the exception noted here. One would expect the glide planes to tend to line up parallel to the major shear zone so that the low seismic velocities would be perpendicular

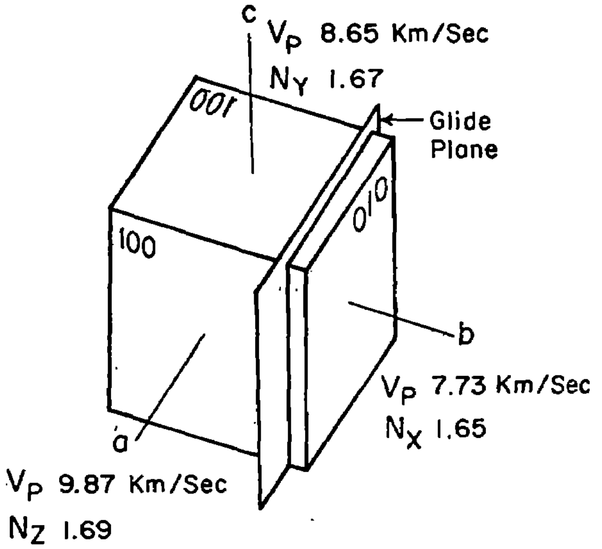

Fig. 1. Orientation of the principal optical directions, seismic velocities (Vp) and glide plane for magnesian olivine

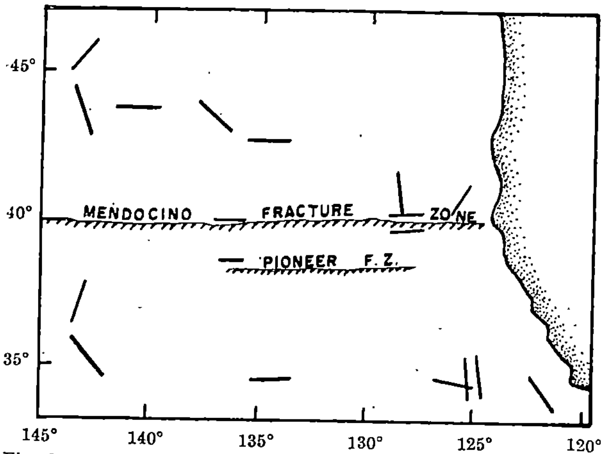

Fig. 2. Location of seismic refraction profiles in Raitt's study of Mendocino fracture zone area off California

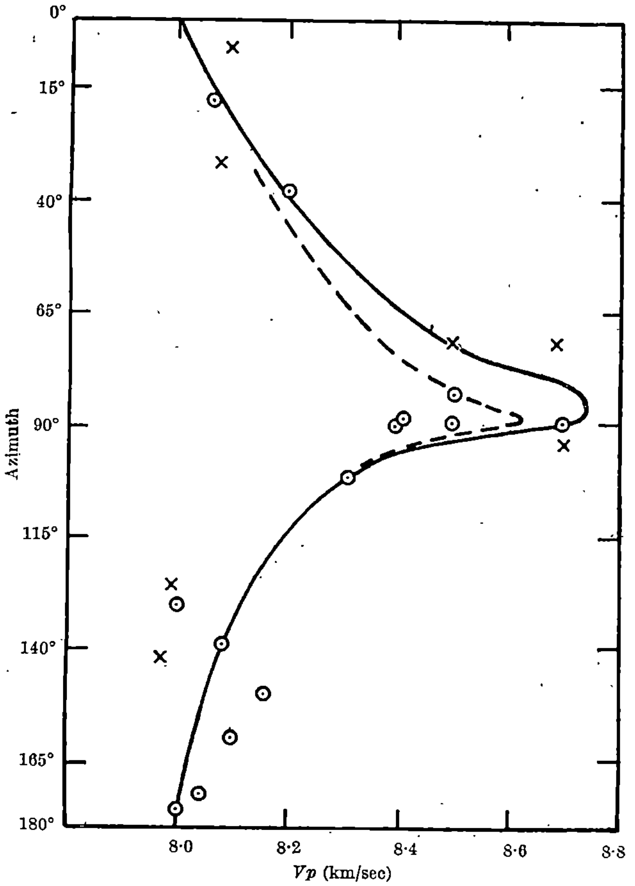

Fig. 3. Seismic velocity, Vp, versus azimuth. Circles, Mendocino area; crosses, Maui area; dashed curve for former, solid curve both areas combined

to it and the higher velocities parallel to it. The Mendocino fracture zone trends almost exactly east–west. Fig. 3 shows the seismic velocities below the Moho versus azimuth and presents a striking agreement between the hypothesis and the observations.

As a further test of the hypothesis, seven recent determinations of velocity versus azimuth by George Shor[6] for the area in the vicinity of the Molokai shear zone (N. 80° E.) were added to Fig. 3, and corroborate the conclusion previously made.

In constructing Fig. 3, all Raitt's measurements available to me were used except those where the sub-Moho velocity was less than 8·0 km/sec. It is evident that in some areas the mantle is altered probably by partial serpentinization so that lower velocities prevail. In an area near the California coast just north of the Mendocino scarp, low velocities for all azimuths were encountered. If this group is taken separately the olivine present still imposes the same velocity differential with respect to azimuth as in the remainder of the area (one near east–west has a seismic velocity of 7·9 km/sec and two which are nearly north–south have velocities of 7·4 and 7·5 km/sec). To determine anisotropy in oceans where no guiding fracture zones are evident it would be well to shoot on three lines at 120° to each other. A single velocity does not mean much because there must normally be other constituents than olivine and pyroxene in variable amounts in the rocks immediately below the M discontinuity. If this were not so the average velocity under the oceans would be near 8·5 km/sec rather than the observed 8·1 km/sec. Thermal expansion in areas of high heat flow, dilation by shearing, fluids such as water in pore space, and in particular hydrated minerals such as serpentine all tend to lower velocity. The amount of such effects is variable from region to region.

As can be seen in Fig. 1, indices of refraction for olivine vary sympathetically with seismic velocities, which is to be expected. Oriented samples from St. Paul's Rock on the mid-Atlantic ridge were examined under the petrographic microscope. These rocks are strongly deformed peridotites–mylonites[7]. Shearing and granulation have been severe so that olivine grains are less than 0·05 mm in diameter. Though it is not possible to orient individual olivine grains and construct a petrofabric diagram, it is evident that most of the grains have a similar optical orientation, extinguishing under crossed Nicols roughly parallel and at right angles to the main shear plane. It was found that $N_{x'}$ (the fast vibration direction for light and the slow seismic velocity direction) is perpendicular to the plane of shearing.

Whereas tests for seismic anisotropy should be made in other parts of the oceans, it seems likely that the oceans everywhere have a fabric such that directions in which the material has flowed in the solid state can be determined. The low velocity is perpendicular to the shear direction and high velocity parallel to it. The low velocity is also parallel to the linear magnetic anomalies off California.

Applying the very fruitful idea introduced recently by Vine and Mathews[8], rates of flow could be added to the structural picture if reversals of the Earth's magnetic field had a regular periodicity. When it becomes possible to drill the hard rocks of the ocean floor an absolute age can be given to a particular linear magnetic anomaly. A series of linear anomalies may then be counted much as are varves on land and another age determination made at perhaps thirty cycles distant so that a relatively good

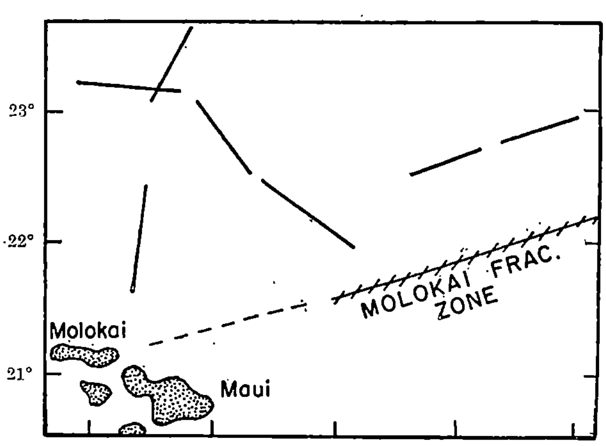

Fig. 4. Location of seismic refraction profiles in Shor's study of area north of Maui, Hawaiian Islands

figure could be obtained for the length of a cycle. Using these tools the structure and history of the whole ocean floor can probably be worked out much more rapidly than the more complicated land surfaces of the Earth. Unfortunately, if my general concept[9] of the history of ocean basins is correct, only something less than the last 10 per cent of geological history can be found in the oceans.

I thank R. Raitt and G. Shor, whose seismic refraction data I have used as a basis for this communication; Ian MacGregor, who collected the oriented samples from St. Paul's Rock; and W. M. Elsasser for helpful discussion of the general problem. This work was supported by a contract with the Office of Naval Research, *Nonr* 1858 (10).

Electrical Resistivity of the Crust and Upper Mantle at Eskdalemuir, South Scotland

The oscillations in telluric field in magnetic north–south and east–west directions were recorded at Eskdalemuir (55° 19′ N., 3° 14′ W.), South Scotland, over three weeks in December 1963. The electrodes consisted of 2 ft.^{2}, 0·25-in. steel plates buried 2,000 ft. apart. The recording and the La Cour magnetograms made at the observatory yielded the data for this magnetotelluric examination. The period of recorded oscillations ranged from 20 sec to 100 min. The records were visually analysed and only the pulsations with good sinusoidal shapes and having no noticeable vertical component were considered. By the courtesy of G.P.O. Engineering Department, magnetotelluric data were also collected on the cables across the Irish Sea. This was, however, considerably affected at the lower end of the spectrum by near surface features and will only be referred to here. A paper covering the details of this investigation is under preparation, and will be published elsewhere.

The amplitudes of simultaneous oscillations of period T in terrestrial electric (E) and magnetic (H) fields (usually 5–10 mV/km and 5–10γ respectively) have very significant correlation (coefficient 0·75–0·95), but their ratios show considerable scatter. This scatter is independent of period as well as amplitude of oscillations. The mean E/H is used to find apparent resistivity ρ_a according to the formula $\rho_a = 0{\cdot}2T(E/H)^2$ given by Cagniard[1]. The plot of mean ρ_a and its standard error against T is shown in Fig. 1 for profiles in both directions. The two are not identical, thus showing that the surface is anisotropic. Unfortunately, very few oscillations occur simultaneously in both components and it is not possible to evaluate the anisotropy factor. However, the individual values of E/H in the two directions are not very different from normal scatter and both profiles may be combined by taking the geometric mean of ρ_a at each period. The mean profile thus obtained is given in Fig. 2.

The apparent resistivity in the profiles over the Irish Sea is so low at longer periods of the spectrum that the continuous variation of resistivity down to the depths involved is not possible. On the other hand, plausible values are obtained if a layered distribution of resistivity is assumed. The theoretical curves of best fit for the data and corresponding resistivity distributions are also given in Figs. 1 and 2. Mutual consistency of profiles given here as well as five profiles over the Irish Sea helped in choosing the particular standard curves out of many which fitted the data.

The observed spectrum does not extend to sufficiently low periods to establish the depth of the first discontinuity with certainty, but the middle layer must be several km thick. The second discontinuity situated at the

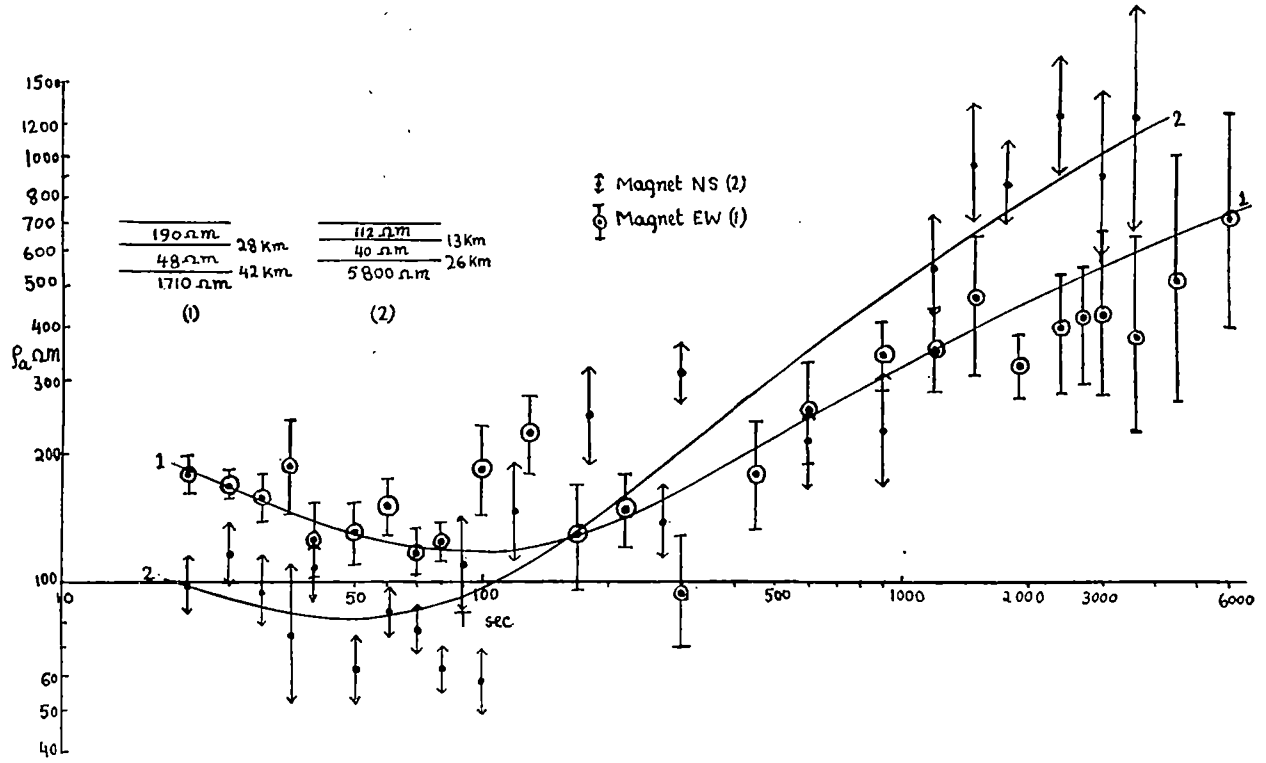

Fig. 1. Observed magnetotelluric profiles at Eskdalemuir

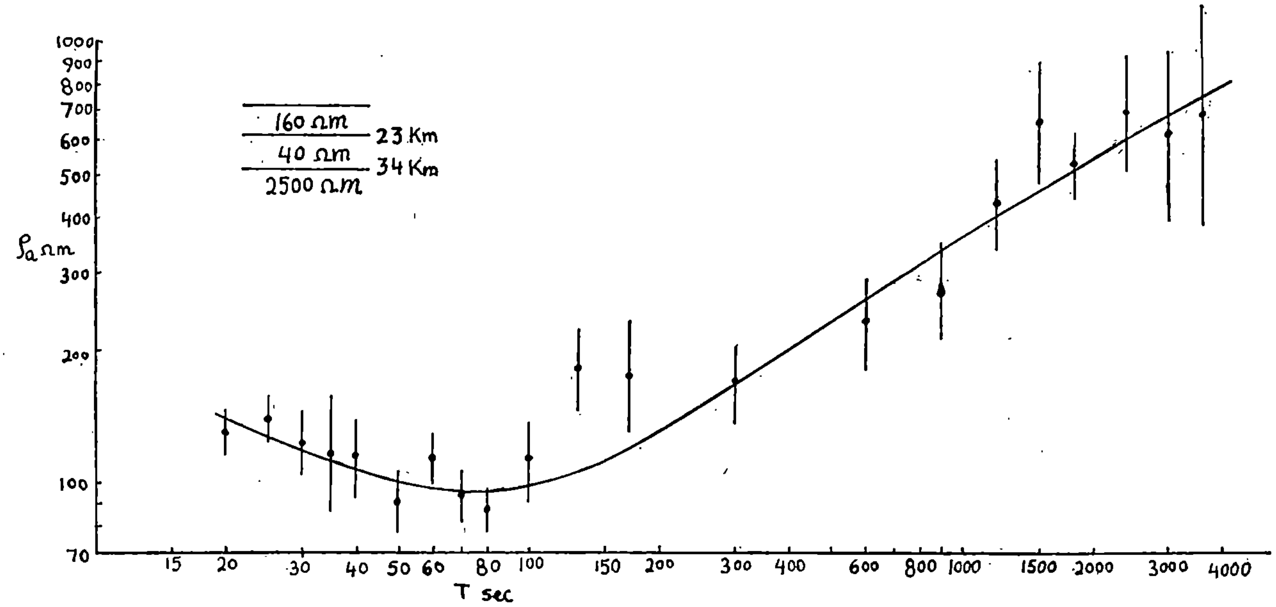

Fig. 2. Mean magnetotelluric profile at Eskdalemuir

depth of 34 km in Fig. 2 and at 29–33 km in the Irish Sea profiles may correspond to Moho. No other measurements of the thickness of the crust in this region are known, but these depths show good agreement with seismic investigations elsewhere in western Europe. The resistivity of the top of the mantle is of the same order as found by other workers, but the profiles indicate the presence of a conductive layer at the bottom of the crust. The resistivity in this depth range varies greatly from place to place; from 1 Ω*m* below the Arctic Sea[2] to 10,000 Ω*m* in Massachusetts[3]. The temperatures necessary to explain these differences by variation in ionic semi-conduction are too high[4] to be unnoticed in the measurements of heat flow in deep wells[5], and it is probable that the impurity semi-conduction plays a more important part in the crust. This explanation is supported by the laboratory investigations of Parkhomenko and Bondorenko[6], who find that the resistivities of different samples of the same rock can be very different at high temperatures and pressures.

I thank Mr. Lamden of the Atomic Weapons Research Establishment, Aldermaston, for permission to use their cables at Eskdalemuir; the staff at the Meteorological Office Observatory, Eskdalemuir; and Dr. C. D. V. Wilson of the Department of Geology, University of Liverpool, who supervised this work.

PHYSICS

Calorimetric Dose Measurements with 35-MeV Betatron Electron Radiation

THE calorimetric system developed in the International Atomic Energy Agency (IAEA) Laboratory, Vienna, has been used for measuring the electron dose distribution in a 'Lucite' phantom. It may be recalled that the calorimeter[1] is calibrated in rads (1 rad = 100 ergs/g) by accurate determination of the electric energy input.

The 35-MeV electron beam (field size 14 cm × 14 cm at 110 cm focal distance), generated by a Brown Boveri betatron[2], was used for the investigation.

Preliminary measurements with thermistors of the same type and embedded equally in the same material as that used in the calorimeter have shown that they were not affected by doses up to 30 krads produced by 35-MeV electrons.

Further measurements were then undertaken to test the response of the calorimeter in a 'Lucite' phantom (70 mm of material in front, and 30 mm behind the absorber) irradiated with 35-MeV electrons at dose rates of about 250 rads/min. Comparison between the calorimeter and the radiation monitor of the machine (a flat ionization chamber measuring the total electron flux behind the collimators) in the range up to 1,000 rads showed a linear response of the calorimeter with respect to the dose and that the readings of the monitor were proportional to those of the calorimeter.

Simultaneous measurements with a Thimble-Head Ionization Chamber (Baldwin 'Ionex *MK* 3*', volume of the chamber 0·6 c.c.) have shown that this instrument developed serious errors when the applied doses exceeded about 400 r. The errors manifest themselves as a heavy apparent dose-leakage above the critical dose value; for smaller doses, however, the measurements were reproducible to within ± 2 per cent.

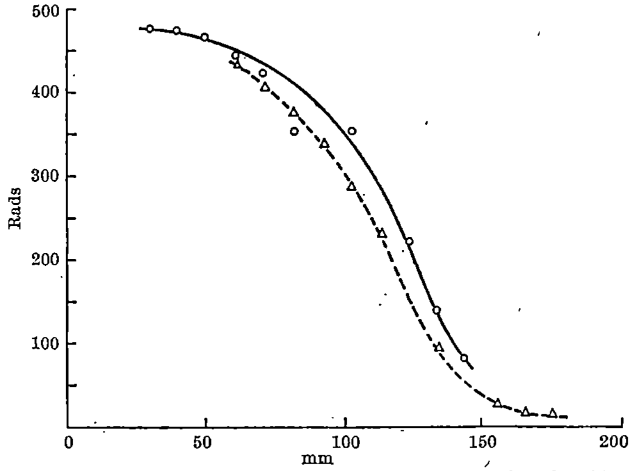

Fig. 1. ○, Calorimeter (rads); △, Thimble-Head Ion Chamber (r)

Dose measurements comparing the calorimeter–dosimeter and the Baldwin instrument, therefore, had to be restricted to doses below 400 rads.

For measurements of 35-MeV electron radiation dose distribution along the axis of the beam, the calorimeter and Baldwin ionization chamber were placed in the 'Lucite' phantom. The 'Lucite' thickness in front of these devices was varied between the limits given in Fig. 1. Here, the full curve represents the calorimetric results, and the dotted curve the ionization values. The results of both methods were reproducible within ± 2 per cent. It is interesting to note that the ionization values are systematically lower than the calorimetric values, with a discrepancy up to 25 per cent.

In a further investigation of this difference the present investigation will be extended to a wider range of radiation energies (also including X-rays) using the calorimetric method and different types of ionization measuring equipment.

We thank Dr. M. Sempert and his staff at the Brown Boveri Laboratory, and Mr. J. Haider (I.A.E.A.), for their kind co-operation.

Logarithmic Pressure Scale

WITHIN the past year discussions have been published[1,2] which have been critical of the present system of vacuum designation and have advocated logarithmic scales. We have been independently[3] considering this same problem and have arrived at a more specific proposal than that found in refs. 1–3, which encompasses the whole range of pressures from that of the 'highest' vacuum (that is, lowest molecular density) we can attain to the greatest pressures we choose to discuss. It will not ascribe negative values to pressures greater than atmospheric[2].

We propose a logarithmic scale for which there is, as has been pointed out[2], precedence in the chemist's pH system. An additional precedent is that of acoustical, electrical and electronic engineers, who use the 'bel' to denote a ten-fold change in power, and, therefore, a unit change in its logarithm. They find the 'decibel', one-tenth of this step (implying an accuracy of ± 12 per cent), sufficient for expressing these quantities to the precision with which they are ordinarily measured. It is important to note that in neither case is the conversion to an absolute linear system onerous when it is necessary, and such is the adaptability of the human mind that the logarithmic values very soon evoke a direct conceptual response.

We recommend, specifically, that the logarithm to base 10 of the absolute pressure in bars be adopted as the measure of that pressure, and that a unit step on this scale be termed 'one Boyle'. Just as in the acoustical example, it will ordinarily be true that specification to a precision of one 'deciBoyle' (dB), corresponding to a change of 0·1 in the logarithm of pressure, that is, ± 12 per cent. will be sufficient in vacuum work for all but the most precise purposes. It would be convenient for both vacuum and high-pressure work to place the zero point of this scale near one atmosphere, rather than, say, at the present arbitrary reference point at 1 mm mercury. For precise definition, however, we propose to use the 'bar'. Thus, the exact reference point is a pressure of 10^5 joules/metre^3 (10^6 dynes/cm^2), which is greater by the factor of 1·01325 than one standard atmosphere[4], and which, in practice, can often be taken to be 1 atmosphere with negligible error. Thus negative quantities denote vacuum on the proposed scale.

Conversion of a pressure reading of p units to the proposed logarithmic scale is accomplished by the formula:

$$\text{dB} = 10 \log_{10} p + C$$

where the constant C is ten times the common logarithm of the unit prèssure expressed in bars. Values of C for several common systems of units are given in Table 1.

Table 1. CONSTANTS FOR CONVERSION FROM PRESSURE TO THE DECIBOYLE SCALE

Unit	Unit expressed in bars (ref. 4)	C
Bar	1	0
Kilobar	10^3	30
Barye	10^{-6}	−60
Torr	$1·3332 \times 10^{-3}$	−28·7509
Inch mercury	$3·386 \times 10^{-2}$	−14·7026
Millibar	$\times 10^{-3}$	−30
Psia	$6·894 \times 10^{-2}$	−11·6167
lb./ft.^{2}	$4·788 \times 10^{-4}$	−33·1980
g/cm^2	$9·807 \times 10^{-4}$	−30·0847
Cm H_2O at 20° C	$9·789 \times 10^{-4}$	−30·0928
In. H_2O at 20° C	$2·486 \times 10^{-3}$	−26·0444
Atmosphere	1·01325	+0·0572

For example, when p is given in torr, the conversion formula becomes:

$$\text{dB} = 10 \log_{10} (p \text{ torr}) - 28·7509$$

and, for p in atmospheres, it is:

$$\text{dB} = 10 \log_{10} (p \text{ atm}) + 0·0572$$

The two common reference points, 1 torr and 1 atmosphere, are separated by 28·8081, or roughly 30 dB.

Table 2 lists some important points on the pressure scale in the proposed system. Note that the 'torr' is not commonly used in high-pressure work. The advantage of a single logarithmic scale, equally applicable to extreme vacuum and to high pressure, is apparent.

Table 2. COMPARISON OF CONVENTIONAL AND LOGARITHMIC PRESSURE SCALES

	Ref.	p	dB
Normal atmosphere	4	$1·01325 \times 10^5$ joule/m^3	0·0575
Sub-atmospheric			
Vapour pressure of water at 300° K	4	26·7 torr	−14·5
Triple point water—ice I—vapour	4	4·6 ,,	−22·18
'One mm of mercury' = 1 torr	—	1	−28·75
Vapour pressure of mercury at 300° K	4	$2·18 \times 10^{-3}$ torr	−55·4
'One μ of mercury'	—	1×10^{-3} ,,	−58·8
Lower limit of McLeod gauge		1×10^{-6} ,,	−90
Lower limit of ionization gauge		1×10^{-11} ,,	−140
Super-atmospheric			
Critical pressure of air	4	37·2 atmospheres	15·7
Critical pressure of water	4	224·9 ,,	23·5
Triple point water—ice I—ice II	4	2,115 ,,	33·25
Triple point water—ice V—ice VI	4	6,380 ,,	38·05
Phase transition bismuth I—bismuth II	5	25,400 bars	44 05
Phase transition bismuth V—bismuth VI	5	89,400 ,,	49·51
Pressure at the Earth's centre	6	$3·64 \times 10^6$ bars	65 61

Before concluding, there are some points raised in the earlier correspondence which merit attention. It must be agreed that the quantity which the ion gauge samples is more closely related to molecular density than to pressure and it is the molecular density in an experimental enclosure which is most often the quantity of physical interest. It is also true, however: (1) that the ion gauge density as calibrated is really uncertain to the degree that the pertinent temperature within the gauge is uncertain; (2) that the molecular density in the experiment is to be found only by correcting the gauge reading in accordance with the temperature in the experimental enclosure. Surely we should not make the adoption of a rational and useful pressure-designation system contingent on the technical difficulties of measuring molecular density.

By way of recapitulation we enumerate the advantages of the deciBoyle system: (1) It furnishes a unified scale encompassing the whole range from the smallest to the greatest pressures. (2) It centres around a convenient and absoute reference value, approximately one standard atmosphere. (3) The numeric expresses in its units place the accuracy attributable to the majority of pressure designations (that is, ± 12 per cent) which lie outside the range of the simple barometric column or the McLeod gauge.

METALLURGY

Distribution of Twins around a Microhardness Indenter in Close-packed Hexagonal Metals

Attempts have been made to explain the hardness anisotropy of close-packed hexagonal metals in terms of the slip and deformation twinning modes which are available$^{1-5}$. As a result, simplified models of the stress system around an indenter have been developed in which the shear stresses acting adjacent to the indenter facets are resolved in the slip and twinning planes and in the respective shear directions. The hardness variation was shown to be consistent with the variation in the resolved shear stresses for twinning in the basal planes of zinc, magnesium^3 and beryllium^4 and in the prism planes of zinc and magnesium^3. It was therefore concluded that the hardness anisotropy could be due to twinning.

Following a metallographic examination of the deformation produced in indented zinc and magnesium crystals, it was suggested that slip alone could readily account for the hardness anisotropy found in prism planes and indirectly for the anisotropy in the basal planes^5. However, it was noted that twins were sometimes nucleated around the hardness impressions. It is proposed in this communication to consider in more detail the twinning mode of deformation and to compare the observed distribution of twins around a Vickers diamond pyramid indenter with that predicted by the resolved shear stress models already referred to here.

An impression in the basal plane of magnesium is surrounded by twins at the free surface, whereas in zinc few twins are visible^6. If the surface layer is removed after indenting, twins are found beneath the impression in zinc but not in magnesium. The distribution of twins around an indenter in the $\{10\bar{1}0\}$ prism plane of magnesium is similar to that found in the basal plane of zinc^{5,6}. A similar distribution of twins is also found when a Knoop indenter is used. These observations are summarized diagrammatically in Figs. 1 and 2. It can be seen that although the predicted resolved shear stresses for twinning are almost identical for the equivalent planes in both metals, for the basal planes twins are only found in magnesium around the impression and in zinc below the impression and vice versa for the prism planes.

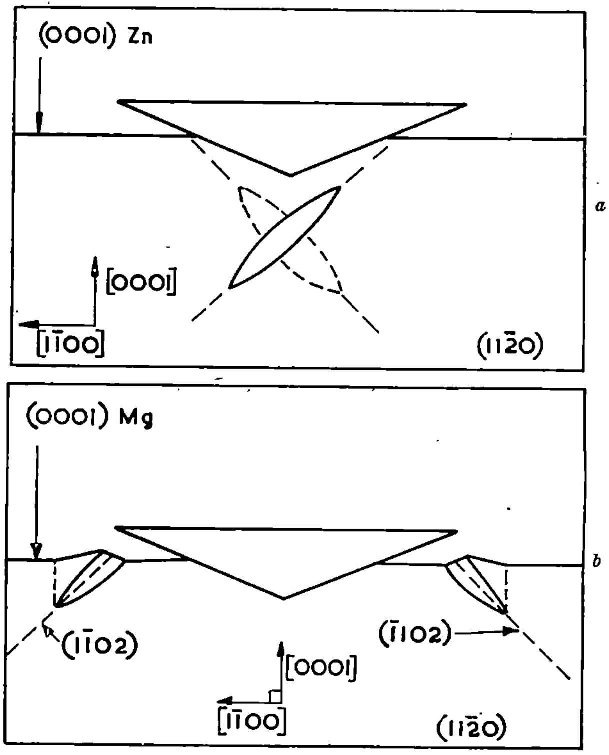

Fig. 1. Distribution of twins around an impression in the basal plane of: (*a*) zinc; (*b*) magnesium

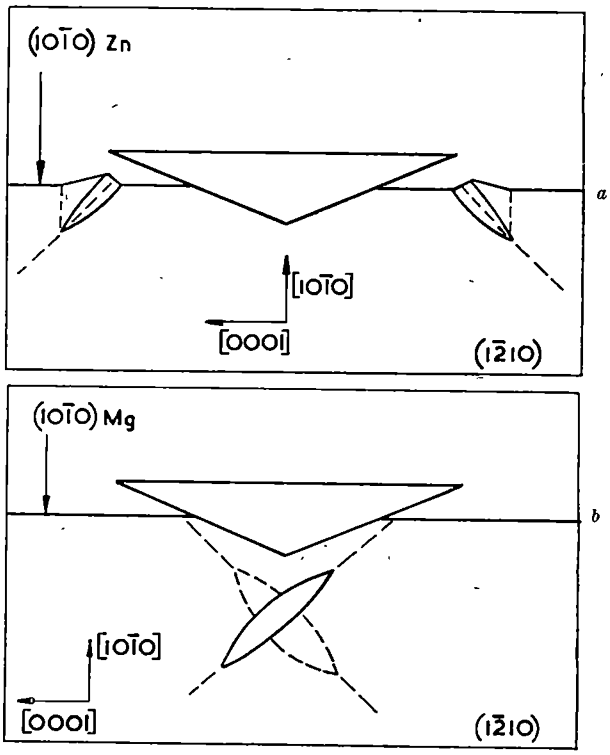

Fig. 2. Distribution of twins around an impression in the prism plane of: (*a*) zinc; (*b*) magnesium

If the changes in shape^{7,8} associated with twinning are considered, the twin distribution can be readily explained. For example, compressive stresses parallel to the *a*-axis favour twinning in magnesium while in zinc compressive stresses parallel to the *c*-axis favour twinning: if the radial compressive stresses around an indenter are resolved parallel and normal to the indented surface, the twins would appear to form in order to relieve the compressive stresses. Clearly a resolved shear stress criterion alone is insufficient to account for the observed distribution of twins and any analysis which attempts to relate deformation twinning with hardness anisotropy must take into account the dimensional changes which occur during twin formation.

It is significant that the hardness anisotropy in the basal planes of zinc and magnesium is similar[5] although the number of twins and their distribution differ in these metals. This suggests that the anisotropy is due to slip rather than twinning, in agreement with the previous results[5]. The effect of indentations on twins already present has also been examined and supports the observations recorded here[6].

Grain Growth in Cadmium

Much has been written of the growth of the component crystalline grains which occurs when a metal is maintained at a constant high temperature, but hitherto no simple law of growth appears to have been established. Working with cadmium, we have found laws which hold with precision for that metal. Whether they hold for other metals, in particular for metals of face-centred cubic structure, is a matter which we propose to investigate.

In a specimen of which the average grain size is below a certain limit, maintained for a long period at a given temperature, the grains grow to a stable size characteristic of that temperature. If n is the average number of grains intersected by a unit length, taken at random, and n_i, the initial value, is about 1·6, or less, times the stable value n_T ultimately attained, then the law of decrease of n, which is the reciprocal of the average diameter, is:

$$n = n_T\,(1 + pe^{-qt})$$

or:

$$\frac{n - n_T}{n_T} = \frac{\text{number of mortal grains}}{\text{final number of grains}} = pe^{-qt}$$

when p and q are constants. We use the term "number of mortal grains" to indicate the number that vanish in the course of annealing at a given temperature.

This law is obeyed within the limit of experimental error, which is well less than 1 per cent of the value of n. It has been established that no change in the value of n_T occurs in weeks.

If the initial grain size is much smaller than that given by $n_i = 1·6\ n_T$, then there are two preliminary stages of growth, first, a very rapid increase of grain diameter, which at high temperature may lead to a ten-fold increase of the average grain diameter in a matter of seconds, and a second stage in which the exponential law is gradually approached. We have an explanation to offer for this behaviour.

The variation of q with temperature is given by the simple law $q = ae^{-\varepsilon/kT}$, where a and ε are constants. The variation of the stable n_T with temperature is given by $n_T = \dfrac{A}{(T - T_0)^2}$, where A and T_0 are constants.

It is hoped to publish shortly an account of the experiments in question, with an attempted explanation of the results.

RADIATION CHEMISTRY

Changes in Titanium Dioxide-Silver Nitrate Mixtures after Ultra-violet Irradiation

The photo-darkening of titanium dioxide–silver compound mixtures has been observed by Förland[1] and Goetz and Inn[2] among others. Förland attributed the discoloration to the oxidation of the silver ion to AgO, though Goetz and Inn claimed that it was due to the reduction of the silver ion to metallic silver.

During investigations into this reaction, interesting reflectance changes were observed on specimens after they had been exposed to ultra-violet radiation. The specimens were prepared by mixing 10 gm of a commercial rutile titanium dioxide pigment with 10 ml. of N/10 aqueous solution of silver nitrate. The paste was dried at 80° C for two days in the dark, and formed into compacts to facilitate reflectance measurements. These were evacuated for 1 h at 10^{-2} torr, and then irradiated for two days in a dry nitrogen atmosphere.

The discoloration has a characteristic pink tinge and the reflectance spectrum of a freshly irradiated sample is shown in Fig. 1, curve *A*. The changes after irradiation depend strongly on the presence of moisture, and follow two patterns. If the specimen is kept in a desiccator in the dark, the discoloration slowly dies away, and the reaction appears to be completely reversible. Fig. 2 shows the increase of reflectance at about 5500 Å with time at 20° C. If, on the other hand, the specimen is exposed to moisture, it slowly blackens in the dark. A typical case of a specimen kept in a normal room atmosphere at 20° C is shown in Fig. 1, where curves *B* and *C* show the decreasing reflectance with time. This darkening continues until the specimen appears dark-grey with an overall reflectance of approximately 10 per cent.

This darkening process follows a particular pattern; small black spots form on the surface of the compact, and then grow, bringing about a darkening effect. The formation of these spots depends on the presence of moisture and is irreversible at room temperature. Detailed

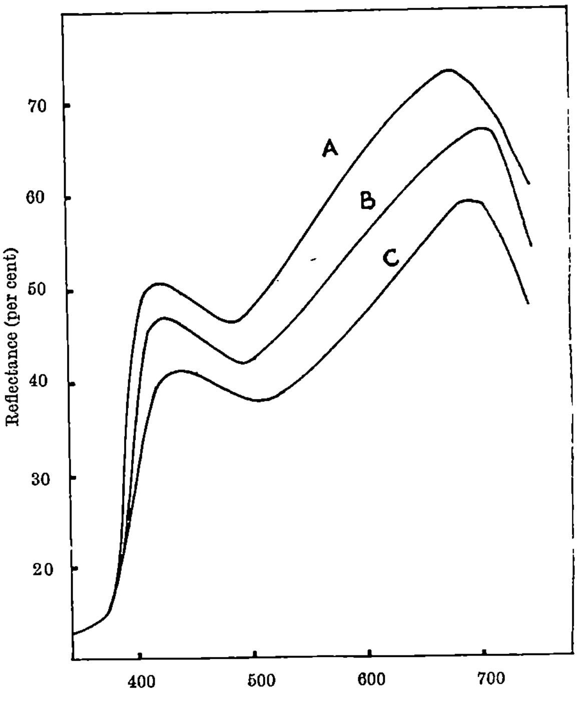

Fig. 1. Reflectance changes measured in a moist atmosphere. *A*, freshly irradiated; *B*, after two days in the dark; *C*, after seven days in the dark

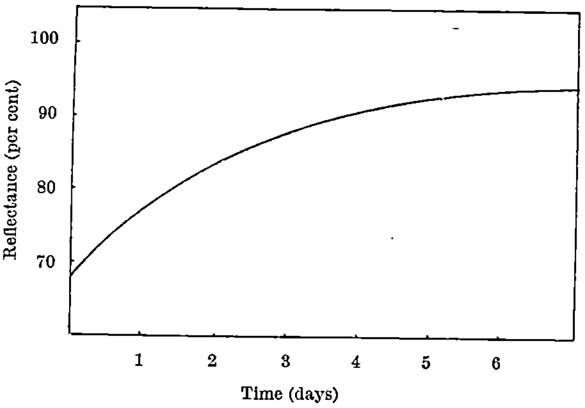

Fig. 2. Reflectance changes measured at about 5500 Å in a dry atmosphere

investigations on the irradiation process to be published elsewhere indicate that these might well be due to colloidal silver, and that the growth is due to silver diffusion over the face of the compact.

The work is part of a general programme dealing with the electrical and surface properties of titanium dioxide. We thank Laporte Titanium, Ltd., for the gift of samples.

Radiation Chemical Reactions in Deoxygenated Peptide Solutions

Investigations by Garrison *et al.*[1] on the radiation chemistry of acetylglycine contributed to the elucidation of the reactions on C2 of the amino-acids participating in the peptide bond.

Simultaneous and independent experiments were carried out in our Laboratory based on our previous observations[2-9] on the increasing importance of recombination reactions with chain-length of irradiated aliphatic amino-acids in deoxygenated solutions. These investigations were aimed at elucidating the type of recombination products formed from peptides, since these could contribute to clarification of the radiolytic reactions of proteins.

0·05 M oxygen-free solutions of leucyl-glycyl-glycine (leu.gly.gly), leucyl-glycine (leu.gly), glycyl-leucine (gly.-leu), glycine, leucine and a mixture (1 : 1) of 0·025 M glycine and 0·025 M leucine were irradiated by cobalt-60 γ-rays (dose $8 \cdot 2 \times 10^{20}$ eV/ml.). The *G*-values are summarized in Table 1.

Table 1. 100-eV Yield from Peptides

(0·05 M aqueous solutions, cobalt-60 γ-rays, dose 8.2.10^{20} eV/ml.)

	leu.gly.gly	leu.gly	gly.leu	leu	gly	leu + gly*
G (-*M*)	2·2	2·4	2·9	2·1	1·57	*G*(-leu) 3 *G*(-gly) 0·9
G(NH_3 + amines)	1·25					
G(CO_2)	0·15					
G(volatile acids)	0·1					
G(dimers, yielding diaminodicarboxylic acids)	0·55					
G(recomb. yielding monoaminodicarboxylic acid)	0·7					
G(carbonyl compounds)	0·1					

* (1 : 1) mixture of 0·025 M leucine and 0·025 M glycine.

Before hydrolysis several peptides giving a weak ninhydrin reaction were observed in irradiated leu.gly.gly solutions. The amount of carbonyl compounds in the unhydrolysed solution was negligible. Glycine was formed in very small amounts (*G* 0·1); decarboxylation also was very low (*G* 0·15) as well as the amount of acids (*G* 0·1).

After hydrolysis, besides leucine and glycine three diaminodicarboxylic acids (*G* 0·5) were observed corresponding to the three major peptides, that is, in order of importance: (1) dimethyldiaminoadipic acid (recombination product of glycine and leucine); (2) diaminosuccinic acid (recombination product of glycine); (3) diaminodimethylsebacic acid (recombination product of leucine). Since none of these products was present before hydrolysis, the three peptides apparently were formed by recombination of two leu.gly.gly molecules, that is, by formation of new C—C bonds.

This fact can be explained by the formation of a radical on C2 of one of the glycine residues in one leu.gly.-gly molecule and on C4 of the leucine residue in another leu.gly.gly molecule. These radicals then recombine, the new peptide being linked by dimethyldiaminoadipic acid (1), which was found after hydrolysis. Another variety of this reaction is radical formation on one glycine residue in each of two leu.gly.gly molecules, recombination leading to diaminosuccinic acid (2). In the third case only the leucine moieties of two leu.gly.gly molecules participate in the reaction under formation of diaminodimethylsebacic acid (3).

The hydrolysed irradiated leu.gly.gly solution also contained monoaminodicarboxylic acids (*G* 0·7) chromatographically corresponding to α-amino-4-methylpimelic acid and α-amino-3-dimethyladipic acid, indicating that *N*-terminal leucine undergoes reductive deamination under formation of isocaproic acid (without breakage of the peptide bond) which combines with a glycine radical in another leu.gly.gly molecule yielding deaminated peptides from which on hydrolysis the corresponding monoaminodicarboxylic acids are formed. Reductive deamination and recombination appears to be a specific reaction of the *N*-terminal amino-acid. In view of *G* 0·7 of these products, reductive deamination is an important reaction of peptides in irradiated deoxygenated solutions.

These facts and the balance of *G*($-M$) and *G*(products) for leu.gly.gly, which is in comparatively good agreement, point to recombination as the primary reactions in the radiolysis of peptides in deoxygenated solutions.

The low value of *G*(CO_2) instigated an investigation of whether carboxylation[8] occurs and leads to consumption of carbon dioxide. However, carboxylation was found to be negligible.

In the irradiated leu.gly solution the same number of peptides was found as with leu.gly.gly, yielding the same diaminodicarboxylic and monoaminodicarboxylic acids as the peptides formed on irradiation of leu.gly.gly. In the hydrolysate acid (1) is present in the highest amount, the amounts of acids (2) and (3) being equal but lower.

In irradiated gly.leu solutions three peptides were observed yielding diaminodicarboxylic acids only. Acid (3) predominates, followed by (1) and a small amount of (2). The monoaminodicarboxylic acid present in the irradiated solution originates from recombination product of the acetyl moiety of acetyl-leucine (deamination product of gly.leu) with the leu moiety of gly.leu, the product being α-amino-4-methylpimelic acid, whereas recombination between the acetyl moiety and the glycine moiety was not observed.

The results show that recombination is the predominant reaction in irradiated deoxygenated peptide solutions. The recombination reactions observed with peptides are analogous to those observed with the free amino-acids. Rupture of the peptide bond is unimportant. In the presence of an aliphatic amino-acid with longer chain, breakage of the peptide bond is practically completely suppressed in favour of recombination as demonstrated by the small amount of carbonyl compounds and amino-acids in the irradiated solution.

CHEMISTRY

Methanolysis of 2,4-Dinitrophenyl *p*-Toluene Sulphonate

The methanolysis of 2,4-dinitrophenyl *p*-toluene sulphonate has been investigated, in continuance of a series of investigations of the methanolysis of nitrophenyl esters[1,2] both under initially neutral conditions and in the presence of tertiary bases, namely, pyridine and its methyl derivatives. In the cases of picryl acetate[1] and 2,4-dinitrophenyl acetate[2] both the neutral and base-catalysed reactions show acyl–oxygen fission:

$$Ar\text{OCOCH}_3 + \text{CH}_3\text{OH} \rightarrow Ar\text{OH} + \text{CH}_3\text{OCOCH}_3 \quad (1)$$

(where Ar = 
). In the case of picryl benzoate[1] under initially neutral conditions, along with acyl–oxygen fission (1), there also occurred some aryl–oxygen fission (2):

$$Ar\text{OCOPh} + \text{CH}_3\text{OH} \rightarrow Ar\text{OCH}_3 + \text{HOCOPh} \quad (2)$$

Reaction (2) did not, however, occur in the presence of tertiary bases. The order of the catalytic constants (k_2^B) are in each case $k_2^{\text{Py}} > k_2^{\text{Co}} > k_2^{\text{Lu}} > k_2^{\text{Pi}}$, whereas the basic strengths are in the order 2,4,6-collidine > 2,6-lutidine > 2-picoline > pyridine. Thus specific and general base catalysis are ruled out. The mechanism is thus nucleophilic catalysis.

The catalysis of the methanolysis of 2,4-dinitrophenyl *p*-toluene sulphonate by pyridine, 2,6-lutidine and 2,4,6-collidine has been investigated at 45° C. The reaction follows two paths leading to 2,4-dinitrophenol (reaction (3)) and the 2,4-dinitrophenyl pyridinium ions (reaction (4)):

$$Ar\text{OSO}_2\text{C}_7\text{H}_7 + B + \text{MeOH} \nearrow Ar\text{OH} + \text{Me}B^+ + \bar{\text{O}}\text{SO}_2\text{C}_7\text{H}_7 \quad (3)$$

$$Ar\text{OSO}_2\text{C}_7\text{H}_7 + B + \text{MeOH} \searrow ArB^+ + \bar{\text{O}}\text{SO}_2\text{C}_7\text{H}_7 + \text{MeOH} \quad (4)$$

Reactions (3) and (4) were followed chemically by measuring respectively the rate of 2,4-dinitrophenol and complex formation. This is essentially a modification of the method of Olivier and Berger[3]. In the case of pyridine, reaction (4) accounts for some 45 per cent of the total reaction, while for 2,4,6-collidine the amount of reaction going by this path was only 14 per cent. None of the reaction in the presence of 2,6-lutidine appeared to go by this route. The reaction products have all been isolated and identified by comparison of the analysis figures and infra-red spectra with those of the pure compounds. The nature of the products enables the mechanism to be postulated[4]. In the cases of pyridine and 2,4,6-collidine it is concurrent sulphur–oxygen fission (reaction (3)) and acryl-oxygen fission leading to the complex (reaction (4)). In the case of 2,6-lutidine, only the former process is observed.

For a given concentration of base, good first order rate-coefficients were obtained for reaction (3), and these, when divided by the base concentration, yielded the catalytic constants. It is found that $k_2^{\text{Py}} > k_2^{\text{Co}} > k_2^{\text{Lu}}$, which is the same order as was found for the picryl compounds[1] and for 2,4-dinitrophenyl acetate[2]. Once again specific and general base catalysis can be eliminated as possible mechanisms and so nucleophilic catalysis must occur, the catalytic constants being determined in part by the basic strengths and in part by the steric effect of the methyl groups of the base. Reaction (4) is also subject to steric effects as the rate coefficients decrease in the order pyridine 2,4,6-collidine 2,6-lutidine.

Further investigations are being made into the reactions in the presence of 2- and 4-picoline, and in the light of these a fuller discussion of the mechanism will be presented elsewhere.

Formation of Phase Test Intermediate of Chlorophyll by Electrolytic Reduction

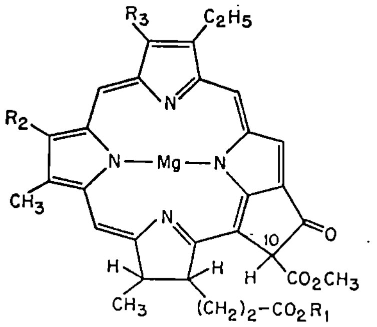
In the course of electrolytic and polarographic studies on chlorophyll and related compounds, we have found that reduction of chlorophyll *a* and *b* in aprotic solvents involves an unusual sequence of events which differ markedly from those observed in protolytic solvents[1,2].

d.c. Polarographic measurements were made in dimethylsulphoxide solvent (distilled from calcium hydride), using 0·1 M tetrapropylammonium perchlorate as supporting electrolyte and an aqueous calomel anode, taking precautions to minimize water diffusion. Controlled potential reductions were carried out at a platinum gauze cathode, using a mercury pool anode and reference aqueous calomel electrode. The electrolysis apparatus permitted also thorough deoxygenation and determination of the absorption spectrum of the solution.

Polarographic results for chlorophyll *a* and some derivatives (Fig. 1) are presented in Table 1. Two waves were observed for all compounds[1,2] and heights for both waves were linear in the square root of the mercury head. The spectral changes following electrolytic reduction of ethyl chlorophyllide *a* at the plateaux of either the first (−1·3 V) or second (−1·6 V) polarographic waves are given in Fig. 2. The resultant spectrum (3, Fig. 2) is unequivocally that of the phase test intermediate (*V*, Fig. 1), as shown by comparison with published spectra[3,4] and by formation of the identical spectrum on addition of aqueous potassium hydroxide. In further agreement with this identification are the following observations on the electrolysed solution: (1) no electron spin resonance was obtained; (2) addition of deoxygenated boric acid solution gave quantitative recovery of *I*; (3) bubbling with air or addition of iodine regenerated a chlorin-type spectrum. Similarly, clear phase-test intermediates were obtained when chlorophyll *a* and *b* were electrolysed.

In two separate electrolyses at the potential of the first wave, coulometric analysis showed that 1·1 and 1·3 electrons were taken up, respectively, per chlorophyllide *a* molecule. Following the reduction, attempts to reduce the solution further at the plateau of the second wave gave no current flow, nor could the solution be oxidized at a potential 0·2 V anodic to the first wave of *I*. Since the product of reduction at the first polarographic wave is reduced at the second wave, in contrast to the behaviour of the phase intermediate, we may conclude that *V* cannot be the primary reduction product.

That the two waves are due to formation of π-electron ions is indicated by similar studies on a series of metallo-tetraphenyl porphyrins, having no other reducible side groups. The polarograms show the same characteristic two waves, with an almost constant separation of 0·44 V, independent of the complexed metal[5]. Previous polarograms of chlorophyll *a* and derivatives in buffered ethanol have also been assigned to chlorin-ring reduction, but show proton involvement in the electrode reaction[1,2]. These results may be reproduced by adding acetic acid to the dimethylsulphoxide solution. Increasing the acid concentration (up to 5 per cent) causes the first polarographic wave to shift anodically and to increase in height at the expense of the second wave. This behaviour is observed also with aromatic hydrocarbons[6], and constitutes further evidence that π-electron ions are initially formed. Finally, the characterization of the porphyrin anions as π-electron ions is substantiated by spectroscopic and chemical evidence[5,7].



Compound (Table 1)	R_1	R_2	R_3	H(C-10)
I	C_2H_5	CH=CH$_2$	CH$_3$	+
II	phytyl	CH=CH$_2$	CH$_3$	+
III	phytyl	CH=CH$_2$	CHO	+
IV	C_2H_5	C_2H_5	CH$_3$	+
V	C_2H_5	CH=CH$_2$	CH$_3$	−

Fig. 1. Chlorophyll derivatives

Evidently, formation of base during the electrolysis would account for the appearance of the phase intermediate. However, addition of chlorophyll to dimethylsulphoxide which had been pre-electrolysed at −1·3 V (very small currents were obtained) gave only the original chlorophyll spectrum. While catalytic base formation cannot formally be ruled out, it is unlikely that the methylsulphenium carbanion[8] would be formed at these low potentials. Moreover, the same polarographic and electrolytic results were obtained in *N*-*N*′-dimethylformamide solvent.

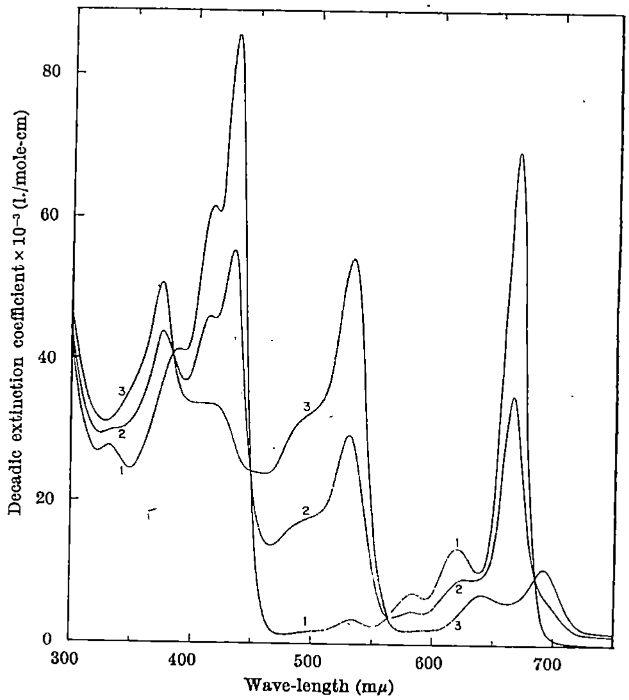


Fig. 2. Spectral changes during electrolysis of ethyl chlorophyllide *a*. (1) Ethyl chlorophyllide *a* in dimethylsulphoxide; (2) intermediate stage of electrolysis; (3) final electrolysis product, phase test intermediate of ethyl chlorophyllide *a*

We therefore suggest the following interpretation of our results. The two polarographic waves are assigned, respectively, to the formation of the π-electron mononegative and dinegative ions of I, II, III and IV. However, under the conditions of bulk electrolysis, the initially formed mononegative radical ion converts to the phase intermediate. This requires the loss of a hydrogen atom from the mononegative radical ion. The nature of the hydrogen acceptor is not clear at this time, and may be the solvent, an impurity, or even another mononegative ion, leading to hydrogen evolution.

If this interpretation is correct, then chlorophyll mononegative ion is unstable with respect to formation of the phase test intermediate and loss of hydrogen to suitable acceptors. Such a transformation may provide a catalytic pathway by which charge-transfer reactions involving chlorophyll may effect hydrogen atom transfer, by virtue of the high stability of the phase intermediate.

This work was supported by grants from the National Institutes of Health (*GM* 108 33-01) and the U.S. Atomic

Determination of Electro-oxidation Products using an Auxiliary Mercury Electrode

THE investigation of the mechanism of electro-oxidation is hindered by the lack of information about the reaction products and intermediates. These can be determined in some cases by ordinary analytical methods. In some cases a current-voltage curve obtained by application of a voltage sweep to the electrode during interruptions of the electro-oxidation can be used for determination of products of the electrode reaction, but usually does not give unambiguous results.

If a small mercury electrode is placed in the immediate neighbourhood of the anode the advantages of the polarographic method, that is, the reproducibility and the large cathodic potential range may be used for the determination of reducible products of electro-oxidation which diffuse from the anode. For a rapid and sensitive determination the method must be modified in some way: (1) the potential of the working electrode at which the products are formed must be controlled by means of a potentiostat; (2) the resistance of the solution between the mercury cathode and the reference electrode must be kept low to make possible the application of the linear voltage sweep oscillographic polarography.

Bearing this in mind, the cell and the mercury electrode have been designed as follows. A platinum platinized anode *A* (apparent area 50 mm^2) placed in the centre of the anodic compartment (Fig. 1) is kept at a constant potential by means of a reference electrode (*RE*) joined through a Luggin capillary. The liquid junction potential between the solutions in the compartments of the anode and of the reference electrode may cause uncertainty in the control of the potential of the anode. Therefore a hydrogen electrode according to Giner[1] in the same solution in both compartments has been used. Hydrogen is generated at a platinum black electrode connected to an auxiliary current source. The electrolysis with a current density of 1 m.amp/cm^2 maintains a constant potential of the hydrogen electrode. The cathode is placed in a third compartment (not designed) which is joined to the anodic part by means of a sintered glass plug. The mercury electrode (*ME*) consists of a platinum wire (diam. 0·4 mm) sealed in a glass tube which is ground at the end to a flat tip. The electrode is platinized and coated electrolytically with mercury. It is moved by means of a micrometric screw to a definite distance from the anode. A small piece of glass 0·2 mm thick sealed to the tip prevents the short-circuiting of both electrodes. The solution is deaerated by bubbling with pure nitrogen.

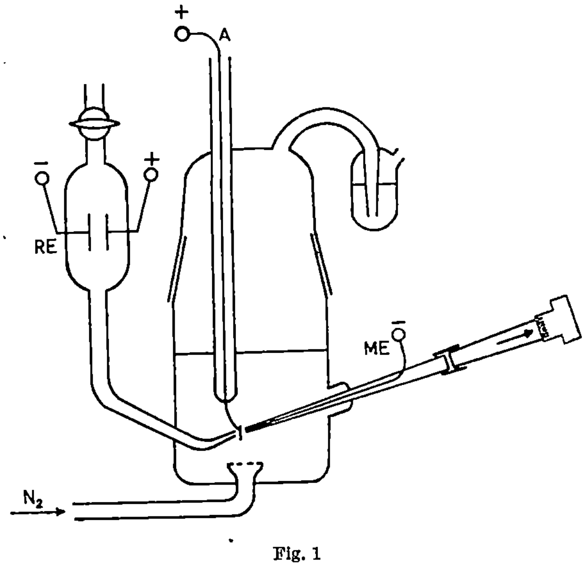

Fig. 1

The cathode (*C*), the anode (*A*), and the reference electrode (*RE*) are connected in a conventional way to an electronic potentiostat (*PO*) (Fig. 2) which is based on operational amplifier units[2]. The mercury electrode is polarized from the differential amplifier (*DA*) through a measuring resistance (*R*). The other imput of the amplifier is switched on a generator (*G*) of a triangular voltage impulse. The anode is earthed and makes the common point of the circuits of the potentiostat and the amplifier, respectively. This connexion is made possible by the fact that the potential of the anode is kept constant by means of the potentiostat. The voltage on the mercury electrode controls the horizontal deflexion of the cathode ray tube of the oscilloscope (*O*), the voltage drop on the resistance (*R*) the vertical deflexion. In this way a current-potential curve is displayed on the screen.

Using this method it was possible to follow quantitatively the rate of formation of formaldehyde during the electro-oxidation of methanol in a buffered solution. The electrolysis at a given potential was switched on and after a delay of 5 min the current-voltage curve of formaldehyde at the auxiliary electrode was recorded. The height of the peak of formaldehyde was compared with the height measured in a solution of a known concentration[3]. The concentration at the anode was then computed using the integrated Fick equation. Similar experiments using a

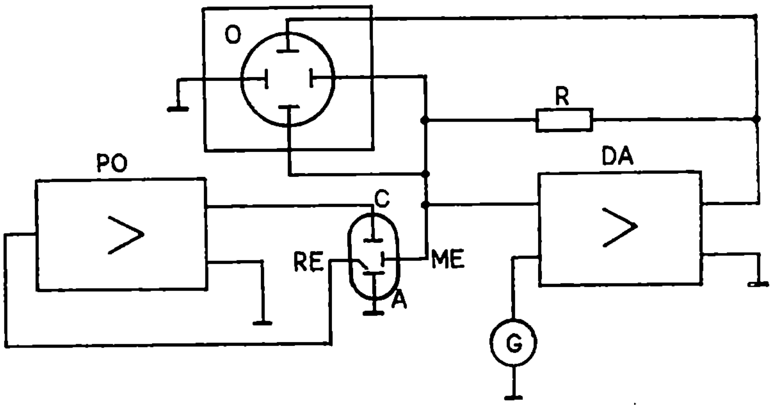

Fig. 2

platinum rotating disk electrode with an auxiliary ring[4] with mercury coating are going on.

BIOPHYSICS

Electron Spin Resonance in Hæmin, Hæmatin and Hæmoglobin at 4·2° K

The electron spin resonance method is capable of giving fairly detailed information concerning the electron structure of molecules having unpaired electrons. In the past few years D. J. E. Ingram *et al.* have made detailed investigations of the electron spin resonance absorption of single crystals of hæmoglobin and myoglobin compounds. The most accurate measurements on high-spin ferrihæmoglobin and ferrimyoglobin compounds have been made at liquid air or liquid hydrogen temperatures and a well-defined variation of g-value from $g = 2$ to $g = 6$ was obtained[1–4]. Very similar g-values were observed in polycrystalline samples of the prosthetic group hæmin at liquid air temperatures[1,2,5]. No electron spin resonance spectrum was obtained in hæmatin. Measurements in frozen aqueous solutions at 170° K on some hæmoproteins have been reported by A. Ehrenberg[6]. I have recently summarized much of this work up to the first part of 1963[7].

I am undertaking an investigation of hæmin, hæmatin and acid ferrihæmoglobin by electron spin resonance at 4·2° K, to obtain as much detailed information as possible. In these biological complexes the iron atom (Fe^{3+}) is held at the centre of the porphyrin plane, surrounded by a square of nitrogen atoms. The different derivatives can best be classified by the nature of the extra two radicals attached to the central iron atom. In hæmoglobin one of these is a nitrogen atom of a histidine amino-acid of the protein, globin, and the other (sixth) position can be taken by a variety of different radicals. In acid ferrihæmoglobin water is at the sixth position. Hæmatin has water at the fifth position and the OH^- radical at the sixth position. Hæmin has a similar structure to hæmatin but has the Cl^- radical in place of the OH^- radical.

Electron spin resonance spectra were observed using a Strand Labs. spectrometer model 601 with a microwave frequency of 9,400 Mc/s and a field modulation of 6 kc/s. The sample cavity for operation at liquid helium temperature is a rectangular, silver-deposited quartz cavity which operates in the TE_{101} rectangular mode. For measurements of the g-values an Alpha Scientific Laboratories nuclear magnetic resonance gaussmeter *AL* 67 was used. Hæmin and hæmatin were obtained from L. Light and Co. and twice crystallized bovine hæmoglobin from the Nutritional Biochemical Corporation.

The samples of polycrystalline hæmatin show no observable electron spin resonance spectrum at room temperature, possibly due to short spin-lattice relaxation time. At 4·2° K they give a very intense line with $g = 6·3$ and two weak lines with $g = 4·35$ and $g = 2·03$ (see Fig. 1). At 4·2° K the intensity of the line with $g = 4·35$ is smaller than at 90° K. This is in accordance with the theoretical considerations given later because, owing to the Boltzmann factor, the line at $g = 4·35$ should be dependent on temperature in the sense that the intensity should diminish as the temperature goes down. In the powder, a statistical distribution of microcrystals is expected. Previous work on line shapes of powder resonance spectra has shown that $g_{\parallel}$ and $g_{\perp}$ can sometimes be deduced from measurements on polycrystalline samples[8–10]. $g_{\perp}$ is most easily obtained by this method because the expression for the mean g value is strongly peaked in the perpendicular direction. In Fig. 1 we are probably seeing peaks due to three separate environments for the Fe^{3+} ion, of which the g near 6 is presumably the $g_{\perp}$ of the usual high-spin situation observed in hæmoglobin and myoglobin compounds.

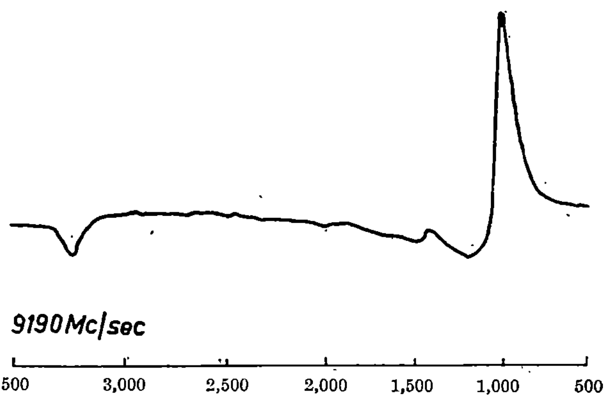

Fig. 1. Electron spin resonance spectrum of hæmatin at 4·2° K

Very similar electron spin resonance absorption was observed for the acidic ferrihæmoglobin, and nearly identical electron spin resonance maxima at $g_1 = 5·82$, $g_2 = 4·25$ and $g_3 = 2·07$ were obtained. For identification of the hæmoglobin used the visible absorption spectrum was measured and typical acidic ferrihæmoglobin maxima at 404·5 mμ, 500 mμ and 631 mμ were found. Similar g-values have been observed for ferric ions occurring substitutionally in glasses[11], in ferric ions of flavin enzymes[12] and also in frozen aqueous solutions of some ferric hæmoproteins[6].

The results for hæmin show that there is a significant difference between the electron spin resonance spectra at 90° K and 4·2° K. At 90° K two electron spin resonance maxima with g-values 2 and 6 were observed. In contrast to these measurements the absorption from hæmin at 4·2° K is a line corresponding approximately to a g-value of 2, and more than a thousand gauss wide. But a very broad line at $g \simeq 7$ was also observed. The coupling of the cavity loaded with hæmin is evidently dependent on the external magnetic field at 4·2° K. It seems most probable that hæmin at 4·2° K is ferromagnetic, but it may be difficult to obtain more precise information with the electron spin resonance method. Measurements of static magnetic susceptibility at 300°–4·2° K are in progress and a systematic survey of this field is planned.

If we assume that the spectrum shown in Fig. 1 is derived from ferric ions in three separate environments we must then ask what are these environments ? The high-spin ferric ion has $S = 5/2$ and it has been argued previously[14] that the spin-Hamiltonian :

$$\mathscr{H}(S) = D\left(S_z^2 - \frac{35}{12}\right) + E(S_x^2 - S_y^2) \qquad (1)$$

is usually adequate for these porphyrin compounds. In equation (1) the x, y and z axes are not necessarily simply related to the porphyrin axes although one might expect them usually to be so. If $E = 0$ we get a g value ranging from approximately $g = 2$ to $g = 6$ with most of the intensity occurring near $g = 6$. Presumably the line near $g = 6$ in Fig. 1 is due to this situation. The line $g = 2$ may well be the typical $g = 2$ line arising from the ferric ion with a fine-structure splitting small compared with the energy of interaction with the external magnetic field, that is, $D \simeq 0$ and $E \simeq 0$. This may be due to some peculiar structure for the hæmatin but is perhaps more likely to be due to a small amount of free ferric ion. Finally the small absorption at $g = 4{\cdot}35$ seems to be genuine. Such a line has been observed for ferric ions elsewhere[11-15] and they have been interpreted as being the case $D = 0$, and E large compared with the magnetic field interaction. If we set $D = 0$ in equation 1 it follows that the ground-term of the ferric ion splits into three Kramers doublets, the middle one of which is predicted theoretically to give an isotropic g value of 4·29 (ref. 15). It has been shown[16] that this behaviour (strictly with E large and D small but not accurately zero) can arise from certain environments. If we suppose that the present g value of 4·35 arises from hæmatin itself then the only one of the three environments considered in that paper which is at all plausible is that of a distorted octahedral arrangement with six identical, or nearly identical, neighbours. Even this environment would seem a little curious in hæmatin and possibly this small line is due to some degradation product.

I thank Prof. J. S. Griffith for giving the theoretical discussion of our experimental data and for kindness in informing us of his theoretical results[16] before publication, also Prof. W. Buckel for the furtherance of this work, and G. Bürk for his assistance in measurements. The programme of which this work is a part was supported by the Deutsche Forschungsgemeinschaft.

Current Pulses in β-Carotene

WE are at present investigating the absorption spectra and photoconduction behaviour, as well as the electric properties of polyene molecules, in particular, of the molecule β-carotene. This molecule occurs widely in plants and animals. Although β-carotene itself does not occur in the visual pigments it can be considered a precursor of retinene, the C_{20} carotenoid, which occurs in the rods and cones of the retina. An attractive feature of this molecule to us was the possibility of growing single crystals and making our electrical and spectroscopic measurements along the different crystal directions. We have been able to make extremely thin crystals (~ 500 Å thick), as well as much larger crystals, and we shall be reporting a full account of the work elsewhere[1]. Here we wish to point out an interesting phenomenon observed during the electrical measurements.

The crystals used for the electrical measurements were crystallized from a benzene–methanol solution and grew as platelets with the faces in the *ab* plane, with typical dimensions of about 0·2 mm thickness and 10 mm^2 area. 'Aquadag' electrodes were used, including a guard ring electrode to eliminate surface effects. Each crystal was mounted on a quartz plate and enclosed in a 'Pyrex' Dewar flask which could be evacuated and heated to any desired temperature. When a β-carotene crystal is heated in a vacuum for several hours at 120° C and an electric field greater than ~4,000 V/cm is applied, we observe current pulses of the type shown in Fig. 1. This shows the current as a function of time when a steady voltage is applied to the crystal. The pulses are of constant frequency, occur in the dark (frequency ~1/10 c/s) and show no signs of decaying over a period of several hours. The effect of irradiating the crystal with light from a tungsten lamp is to increase the current and also to increase the frequency of the pulses. This effect is also shown in Fig. 1. Increasing the electric field also increases the frequency of the pulses.

A surprisingly marked effect on the bulk conductivity of the crystals, due to oxygen, is observed. When oxygen is introduced into the Dewar flask at room temperature the bulk conductivity increases by several orders of magnitude over a period of several hours. Pumping the Dewar flask causes the conductivity to fall slowly to its original value; raising the temperature of the crystal accelerates this process. A similar effect on bulk conductivity has been observed with at least one other type of crystal[2]. The crystal in a vacuum shows the current pulses at temperatures greater than 90° C. However, when oxygen is present, the current pulses occur at lower temperatures and we have observed them to occur at room temperature.

This is the first time, so far as we are aware, that such current pulses produced by a constant voltage have been reported with an organic molecule. Similar effects have, however, been recently observed with a few inorganic semiconductors[3-5]. Germanium, containing gold impurities, produces current pulses at a field of only 3 V/cm, but these were observed with the crystal at temperatures of 20° K. Gallium-arsenide[5] shows the effect at room temperature at 100–200 V/cm. The pulses occur in a similar way to those observed with β-carotene, both with respect to voltage and to incident light. The current-voltage characteristic has a similar deviation from Ohm's law, showing a flattening in the voltage range in which the pulses occur. A detailed explanation of the effect is not yet certain, but it has been shown that the current pulses are associated with a narrow region of high electric field associated with a charged double layer, which moves across the crystal from one electrode to the other and the transit time of which is related to the period of current oscillations[5]. This region of high field can be in many orders of magnitude more than that which occurs on either side of the region. Qualitative explanations of the way in which the high field region is formed seem to vary. A minority carrier extraction process has been described. It has been suggested that the voltage-threshold for oscillations is reached when the width of the charge depletion layer equals the hole drift length[6]. Another explanation has been given in terms of the trapping of hot electrons, leading to the development of a differential negative resistance which, because of its instability, causes a reorganization of field in the crystal and leads to the mobile domain high field structure[4].

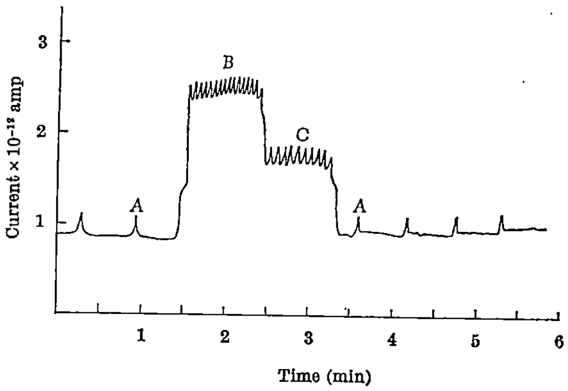

Fig. 1. Current-time relation at constant voltage for a β-carotene crystal in a vacuum showing effect of differing light intensities. *A*, dark; *B*, medium illumination; *C*, weak illumination. Applied voltage, 160 V. Temp., 120° C

It is clearly of interest that organic molecules also can exhibit this effect and we suspect that an explanation of the mechanism will be similar to that provided for the inorganic molecules. The explanations given for the inorganic semiconductors imply that the effect could occur in any heavily compensated high-resistant material, and we expect that other organic molecules, some of which may be of biological importance, will exhibit this effect.

The way in which the frequency of the pulses in β-carotene vary with illumination is very similar to the recording of spike discharges observed with a single optic nerve fibre of *Limulus*[6] when light is directed on to an ommatidium. Here a steady frequency is observed with constant illumination which is approximately linear with the logarithm of the stimulating light intensity. This provokes the question whether a mechanism of the type which we have observed could be an initiating mechanism for the passage of impulses from some receptor site, say the retina, to the optic nerve. It is necessary to be cautious at present about this suggestion. Although it is a precursor, the β-carotene molecule itself does not occur in the visual pigments and these particular pigments will, therefore, require separate investigation. However, even if visual pigments show the effect, then the extrapolation from a single crystal to the biological system may be a difficult one. A satisfactory field strength, sufficient organization and a reasonable minority carrier drift length are some of the requirements for the *in vivo* biological situation. Small voltage differences can give high field strengths if thin enough organized layers are involved and, of course, the visual pigments of the rods are indeed considered to be well organized[7].

We intend to continue investigating β-carotene and also to examine other organic and biologically interesting molecules for this effect. Whether it will prove to have biological significance or whether it is primarily an interesting solid-state electronic effect, which might itself prove to have interesting applications, may be revealed by our further investigations.

Quantity Production of Synchronized Mammalian Cells in Suspension Culture

Synchronized cultures offer advantages in investigations of the sequence of biochemical changes occurring during the life-cycle of the mammalian cell. Such investigations suffer generally because present methods of producing synchronized cells do not provide immediately sufficient material to permit the use of classical analytical techniques. This communication describes a method by which gram quantities of synchronized cells representing a predetermined segment of the life-cycle can be produced.

Induction of partial synchrony in Chang appendix cell monolayers by reversibly inhibiting DNA synthesis with excess deoxynucleosides was initially reported by Xeros[1]. Recently, Puck[2] (using HeLa cells) and Bootsma *et al.*[3] (using heteroploid human kidney cells) showed independently that synchrony in monolayers can be improved by a double blocking technique using excess thymidine. In the work recorded here, a stable diploid line of Chinese hamster ovary (*CHO*) cells[4] was adapted to suspension culture in Puck's F–10 medium with calcium omitted and supplemented with 10 per cent calf and 5 per cent fœtal calf serum. Cultures seeded at a density of 3×10^4 cells/ml. could be maintained in logarithmic growth to a density of 3×10^5 cells/ml. Life-cycle analysis[5] of the *CHO* cell was performed to determine the optimum times for nucleoside addition and removal. Under conditions of suspension culture the generation time was 12 h, the pre-synthetic period (G_1) was 4·5 h, the DNA synthesis period (S) was 4·0 h, the post-synthetic period (G_2) was 3·0 h, and the mitotic interval (M) was 0·4–0·6 h. Using these values for the major segments of the life-cycle the following general procedure for inducing synchrony in suspension culture was devised. A random culture containing 6×10^4 cells/ml. was blocked for a period equivalent to G_2 plus M plus G_1 (about 9 h) by addition of thymidine. Blockade was released by washing and resuspending the cells in normal pre-warmed medium. After an incubation period slightly in excess of the duration of S (about 5 h), a second block was added and the cells again incubated for a period of 9 h. During the latter incubation period, the entire population presumably accumulated at a point immediately prior to S. Release from the second block, accomplished by again washing and resuspending the cells in pre-warmed normal medium, resulted in all cells entering S as a synchronized wave. Cultures were afterwards sampled at intervals and mitotic indices determined as described previously[5] to assess stability of synchrony for prolonged periods. No significant differences in the quality of the synchrony were observed with blocking concentrations of thymidine ranging from 2 to 25 mM.

Results of a typical experiment using a double thymidine blockage (25 mM) are shown in Fig. 1. Integration of the area under the curve for each generation indicates that in excess of 95 per cent of the population participated in each mitotic wave. The volume of the culture at the time of the first mitotic peak was 900 ml. containing $2 \cdot 2 \times 10^5$ cells/ml., yielding 600 mg of synchronized cells from a single collection.

The utility of this method lies in its adaptability to the production of large quantities of material synchronized within the major segments (for example, G_1, S or G_2) of the growth-cycle. So long as the cells were washed carefully and resuspended in pre-warmed medium, no significant lags or perturbations of the cycle intervals were observed. No constraints on culture volume have been encountered, and 1-g quantities of cells specified as to the life-cycle interval have been provided for investigations involving respiration, isolation of subcellular particles, and histone biosynthesis.

The data presented in Fig. 1 show, however, that the extent of synchrony is subject to rapid decay in subsequent generations. A preliminary investigation was carried out

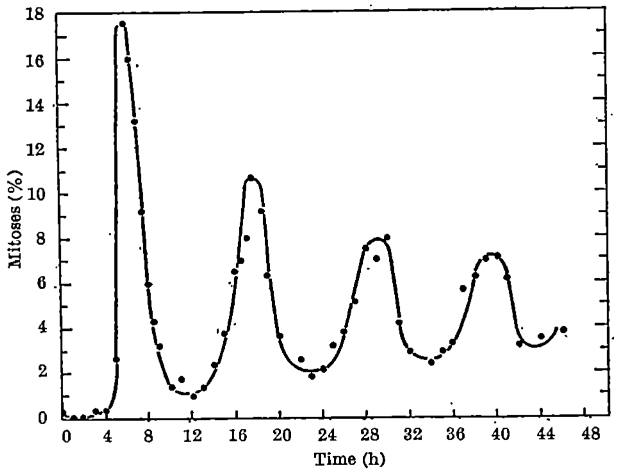

Fig. 1. Mitotic index of synchronized wild-type Chinese hamster ovary cells through four successive generations following release from double thymidine blockade (25 mM)

to test the hypothesis that genetic heterogeneity may account for the rapid reversion of synchronized cultures to random growth[3]. Several clonal lines were derived from the wild-type culture and characterized with respect to generation time and chromosome number. That having a generation time comparable with the wild-type was subjected to the synchronization process during logarithmic growth and followed in two separate experiments through three successive generations. Fig. 2 shows a comparison of decrease in percentage synchronization (as defined by Engelberg[6]) of the parent wild-type cells and cells from the genetically homogeneous clone. These results indicate no great differences in the rate of decay of synchrony between the wild-type line and the line selected for genetic homogeneity. This observation suggests that the capacity of a population of cells to desynchronize may be a fundamental property of the growing cell. Such a mechanism[7] could have significance to survival, since a synchronous population would be subject to annihilation by an insult to which cells in a particular phase of the life-cycle were susceptible but to which cells in other phases were relatively resistant.

These observations suggest also that the degree of synchrony attainable may be an inherent property of the cell. On this basis, synchrony in HeLa cells with approximately 9 per cent variance in generation times[8] may be expected to be superior to that observed in hamster ovary cells for which the variance is about 13 per cent[9]. Preliminary data obtained in our Laboratory by time lapse cinematography of HeLa monolayers are in agreement with results reported by Puck[2], which indicate a three-fold improvement in synchrony over that obtained with *CHO* cells in suspension culture.

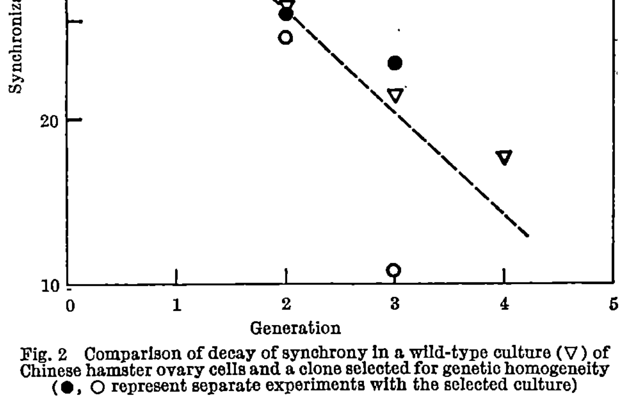

Fig. 2 Comparison of decay of synchrony in a wild-type culture (▽) of Chinese hamster ovary cells and a clone selected for genetic homogeneity (●, ○ represent separate experiments with the selected culture)

BIOCHEMISTRY

In vivo Effect of L-Lysine on Rat Liver Arginase

PREVIOUS work carried out in this Laboratory was devoted to explaining the effective physiological role of ornithine cycle reactions in urea biosynthesis[1,2]. On the basis of the results obtained, serious doubts arose concerning the role of argininosuccinate synthetase in this process as well as with regard to the position of carbamylphosphate as an intermediate in nitrogen transfer from protein to urea. So far as the problem of urea biosynthesis is concerned, we are now investigating the role of arginase in this process. This communication reports *in vivo* inhibition of rat liver arginase activity by a strong competitive arginase inhibitor, L-lysine[3,4].

Male Wistar rats (average weight, 250 g) were fasted for 12 h with water *ad libitum*. L-lysine (3·0 mmoles/kg) in buffered solution at *p*H = 7·2 was injected intraperitoneally. At the same time control rats were injected with phosphate buffer. At various times after injection (Table 1) the rats were killed by decapitation, and the livers were quickly removed; a 10 per cent (v/v) homogenate with Sorensen phosphate buffer, *p*H = 7·2, was obtained in a Potter–Elvehjem glass apparatus at 0° C. Samples were prepared according to the following scheme: homogenate: 1 ml.; L-arginine: 10 μmoles; final volume: 6 ml. with phosphate buffer, *p*H = 7·2. Samples without substrate, as well as samples inactivated at zero time, were also prepared as blanks. The samples were incubated in a water bath at 37° C for 45 min. The reaction was stopped by adding 1 ml. of trichloroacetic acid (10 per cent). Urea was determined on aliquots of the protein-free filtrate according to Archibald[5].

The results (Table 1) indicate that L-lysine administration is able to inhibit arginase activity in liver. The

Table 1. *In vivo* EFFECT OF L-LYSINE (3·0 MMOLES/KG, INTRAPERITONEAL ADMINISTRATION), ON RAT LIVER ARGINASE

Min after L-lysine administration	μMoles extra-formed urea in the incubation mixture		Inhibition (%)
	Control rats	Rats treated with L-lysine	
30	5·5 ± 0·2	4·6 ± 0·1	16·4
60	5·1 ± 0·3	2·3 ± 0·1	56·0
90	5·6 ± 0·0	2·8 ± 0·2	50·0
120	5·4 ± 0·3	4·1 ± 0·2	24·1
150	5·4 ± 0·2	4·4 ± 0·2	18·6
180	5·7 ± 0·2	4·9 ± 0·0	14·0
210	5·5 ± 0·3	5·0 ± 0·1	9·1
240	5·6 ± 0·3	5·5 ± 0·3	0

inhibition reaches a maximum (56 per cent) 1 h after administration; it gradually decreases with the time, and finally disappears after 4 h.

Dhruba Ken[6] pointed out that intravenously administered L-lysine (1 g/day) strongly depresses uræmia in nephrectomized dogs. However, he did not investigate liver arginase activity. At present we are carrying out experiments in order to investigate the effects on urea formation *in vivo* of the observed arginase inhibition produced by L-lysine.

Metabolism of Isomeric Synthetic Polypeptides

Previous investigations[1] demonstrated that a synthetic polypeptide containing D-glutamic acid, D-lysine and D-tyrosine is capable of eliciting an antibody response in rabbits: poly D-Glu^{55}D-Lys^{39}D-Tyr^{6}* elicited an average of 26 ± 33 μg Ab N/ml. in 13/17 animals, whereas its L-counterpart, poly Glu^{56}Lys^{38}Tyr^{6}, elicited 91 ± 52 μg Ab N/ml. in 38/38 animals. In view of this finding, we undertook to determine whether the D-amino-acid polypeptide was capable of being degraded *in vivo*. In addition, we planned to explore the metabolism of another L-amino-acid counterpart of the D-polymer, poly Glu^{58}Lys^{36}Tyr^{6} (No. 2), both as a control for the behaviour of the D-polymer and also to examine further some of the anomalous findings of our previous metabolic study on synthetic polypeptides[2].

In order to determine whether the method of iodination and the amount of polypeptide injected had any influence on the metabolic fate of the polymer, separate aliquots of poly Glu^{58}Lys^{36}Tyr^{6} (No. 2) were labelled by the McFarlane iodine monochloride method[3] and by the Talmage method using free iodine in alkaline solution[4]. The experiments were carried out as previously described[2]; the rabbits received 0·05 per cent potassium iodide in their drinking water beginning two weeks prior to starting the experiments. In addition, the serum volume of the rabbit was measured by isotope dilution with iodine-131-labelled poly Glu^{58}Lys^{36}Tyr^{6} (No. 2), since its value greatly affects the calculation of the early rate of elimination; it was found to be 4·4 ± 0·3 per cent body-weight. Four rabbits were injected intravenously with 60 mg of the polymer labelled by the McFarlane method and five rabbits with 60 mg labelled by the Talmage method. There was no significant difference in the serum elimination patterns of the polypeptide labelled by the different methods. The same experiment was repeated using 10 mg of the polymer and again no difference in elimination pattern was found between the aliquots of the polymer iodinated by the two methods.

The serum elimination patterns of the isomeric polypeptides poly Glu^{58}Lys^{36}Tyr^{6} (No. 2) and poly D-Glu^{55}D-Lys^{39}D-Tyr^{6} were compared by injecting intravenously 10 mg of the L-polymer into each of 6 rabbits and 10 mg of the D-polymer into each of 11 rabbits. The elimination patterns were exactly the same in both cases: less than 1 per cent of the radioactivity remained in the serum after 3–4 days. Hence both the D- and the L-polypeptides are removed from the serum at a very rapid rate.

In 4 of the 9 animals receiving 60 mg of the polypeptide intravenously there was considerably more than 1 per cent of the radioactivity remaining in the serum after 3–4 days. In contrast to this, only 2 of the 34 animals in all the experiments in which 10 mg of either poly Glu^{58}Lys^{36}Tyr^{6} (No. 2) or poly D-Glu^{55}D-Lys^{39}D-Tyr^{6} were injected intravenously had more than 1 per cent of the radioactivity in the serum after 3–4 days. When the sera from the animals which retained radioactivity in the serum was passed through 'Sephadex *G*-25', 80–90 per cent of the radioactivity was retained by the column. Hence the persistence of radioactivity in the serum for more than 3–4 days was due to the presence of free iodine-131 or small radioactive peptides rather than the retention of the intact synthetic polypeptide antigen. From these findings we can conclude that the basic metabolic pattern of synthetic polypeptide antigens is that of rapid elimination from the circulation with less than 1 per cent remaining in the serum after 3–4 days. Our previous interpretation[2] involving two fundamentally different types of elimination pattern, depending on the previous immunological history of the animal, was incorrect. Any deviation from rapid elimination, which appears to occur more frequently with large intravenous amounts of antigen, is due to the presence in the serum of free iodine-131 or small radioactive peptides.

In order to demonstrate that the radioactivity in the urine was due to degradation products of the polypeptides, the urine of the animals injected with poly Glu^{58}Lys^{36}Tyr^{6} (No. 2) and of those injected with poly D-Glu^{55}D-Lys^{39}D-Tyr^{6} was dialysed overnight against running water. All the radioactivity was removed, thus indicating that the radioactivity in the urine was due to free iodide or small peptides from the degradation of the synthetic polypeptide antigens.

A series of experiments was performed in order to quantitate the amount of polypeptide metabolized and to assess the influence of previous exposure to one polypeptide isomer on the metabolism of the other. One

Table 1. Percentage of Polypeptide remaining in the Serum and of Radioactivity excreted in the Urine

The same rabbits received 10 mg of poly Glu^{58}Lys^{36}Tyr^{6} (No. 2) intravenously on day 0 and 10 mg of poly D-Glu^{55}D-Lys^{39}D-Tyr^{6} on day 21

* The standard abbreviations for the amino-acids are used in the nomenclature of the polypeptides. The L-isomers have no prefix and the D-isomers are preceded by D- (for example, D-Glu). The superscripts denote the molar percentages of the amino-acids in the random copolymers and the number in parentheses following the formula denotes the preparation. (The nomenclature scheme is in *Biopolymers*, in the press.) The molecular weights of the polymers are: poly D-Glu^{55}D-Lys^{39}D-Tyr^{6}, 93,000; poly Glu^{56}Lys^{38}Tyr^{6}, 110,000; and poly Glu^{58}Lys^{36}Tyr^{6} (No. 2), 70,000.

group of 5 animals each received 10 mg of poly Glu^{58}Lys^{36}Tyr^{6} (No. 2) intravenously and 21 days later the same animals received 10 mg of poly D-Glu^{55}D-Lys^{39}D-Tyr^{6} intravenously. The results of this experiment are shown in Table 1. A second group of 5 animals received the same polypeptides in the reverse order and the results are shown in Table 2. The serum elimination patterns were the same in all cases. Only 35 per cent of the D-polymer was degraded and excreted in the urine, whereas 95 per cent of its L-counterpart was metabolized. Previous exposure to one polypeptide isomer did not significantly alter the metabolism of the other isomer when it was injected subsequently. Thus, these experiments show that both the L- and the D-polymers are metabolized and the results strongly suggest the existence of D-proteases and D-peptidases in the rabbit. Previous evidence for the existence of such enzymes was given by the work of Tsuyuki, Tsuyuki and Stahmann on the anti-viral properties of poly D-Lys in the chick embryo[5] and on the metabolism of poly D-Lys by pancreatic extracts[6].

The binding of poly Glu^{58}Lys^{36}Tyr^{6} (No. 2) and poly D-Glu^{55}D-Lys^{39}D-Tyr^{6} by serum from unimmunized animals was studied by starch-gel electrophoresis in borate at pH 8·6 and in acetate at pH 5·5. The D- and L-polymers migrated with the same serum fractions: in borate buffer they were bound to proteins in the α- and β-globulin region and in acetate buffer they were bound in the region of the fastest migrating serum protein.

In order to determine the fate of the synthetic polypeptide antigen remaining after the serum-level had reached a plateau and urinary excretion of radioactivity essentially ceased, the organs of the rabbits receiving 60 mg of poly Glu^{58}Lys^{36}Tyr^{6} (No. 2) and those of the rabbits receiving 10 mg of poly D-Glu^{55}D-Lys^{39}D-Tyr^{6} were homogenized and examined for radioactivity. The results are shown in Table 3. Although the total recoveries in these experiments were not complete, it is clear that in the animals receiving the D-polymer much of the radioactivity retained in the animal, and presumably still in the D-polymer, was located in the kidney and, to a much lesser degree, in the liver. The kidneys were examined histologically to see whether there was any morphological damage that could account for the large amount of poly D-Glu^{55}D-Lys^{39}D-Tyr^{6} retained in these organs. No such damage was found and the kidneys were anatomically normal. To summarize, the difference in the metabolism of the isomeric polypeptides lies in their extravascular fate, since they are eliminated from the serum at the same rate but are not degraded and excreted to the same extent, and the kidney appears to be the major organ involved in the ultimate fate of poly D-Glu^{55}D-Lys^{39}D-Tyr^{6}.

Table 3. PERCENTAGE OF RADIOACTIVITY REMAINING IN THE ORGANS OF RABBITS INJECTED WITH THE ISOMERIC SYNTHETIC POLYPEPTIDES POLY GLU^{58}LYS^{36}TYR^{6} (NO. 2) AND POLY D-GLU^{55}D-LYS^{39}D-TYR^{6}

Organ*	Injected with Poly Glu^{58}Lys^{36}Tyr^{6} (No. 2)† (%)	Poly D-Glu^{55}D-Lys^{39}D-Tyr^{6}‡ (%)
Liver	1·1	6·3
Kidney	0·1	32·7
Spleen	0	0·4
Blood	1·2	0·03
Urine	67·7	12·5

* No significant radioactivity in other organs.

† Nine rabbits; 60 mg per rabbit intravenously and killed on day 12 after injection.

‡ Three rabbits; 10 mg per rabbit intravenously and killed on day 15 after injection. (Received 10 mg poly Glu^{58}Lys^{36}Tyr^{6} (No. 2) previously of which 95 per cent was excreted; see Table 1.)

A preliminary investigation of the cellular metabolism of the isomeric polypeptides was undertaken *in vitro* using peritoneal macrophages prepared from ascitic fluid produced in the unimmunized rabbit by injecting mineral oil intraperitoneally 48 h previously. The results for both the D- and the L-polymer were the same: 15–25 per cent of a 200-µg aliquot of polymer was incorporated in 30 min by a suspension containing 2×10^{6} macrophages. Hence it appears that both polymers are equally susceptible to phagocytosis by macrophages.

Finally, we undertook a series of experiments to investigate the metabolic heterogeneity of the synthetic polypeptide antigen poly Glu^{58}Lys^{36}Tyr^{6} (No. 2). Two rabbits weighing about 2 kg each were injected intravenously with 10 mg of poly Glu^{58}Lys^{36}Tyr^{6} (No. 2) labelled with iodine-131. The antigen disappearance pattern was followed closely for 2 h and then the animals were bled. 30 ml. of plasma containing radioactive antigen (1–2 mg) was taken from each of the two rabbits and injected into two other rabbits; the disappearance rates were again followed for several hours. The elimination rate in the second group of rabbits, that is, in those receiving the antigen after *in vivo* screening, was slower than that following the primary injection of antigen. The difference in excretion rate was greatest during the first 30 min: 35 per cent of the antigen was removed from the serum following its initial injection, whereas only 10 per cent was removed after it had previously been screened *in vivo*. Therefore the synthetic polypeptide antigen is metabolically heterogeneous and there is a fraction that is very rapidly eliminated following intravenous injection.

In conclusion, we have demonstrated the ability of rabbits to degrade a polymer composed entirely of D-amino-acids and hence, by inference, have obtained evidence that suggests the existence of D-proteases and D-peptidases. The rates of elimination from the serum for poly D-Glu^{55}D-Lys^{39}D-Tyr^{6} and poly Glu^{58}Lys^{36}Tyr^{6} (No. 2) are the same: less than 1 per cent of the injected dose remains in the serum after 3–4 days. Only 35 per cent of a 10-mg dose of the D-polymer is degraded and excreted in the urine, whereas 95 per cent of its L-counterpart is metabolized. The majority of the retained D-polymer is in the kidney and a small amount is in the liver.

A New Protein Factor promoting Contraction of Actomyosin

RECENTLY a tropomyosin-like protein[1,2], or 'native tropomyosin', has been added to a list of proteins participating in muscle contraction. The sensitivity of myosin *B* to the relaxing action of calcium-binding agents including the physiological relaxing factor is ascribed to the presence of 'native tropomyosin' in it together with actin and myosin. Even with these three proteins, however, properties of myosin *B* could not entirely be represented.

On addition of adenosine triphosphate, synthetic actomyosin tends to show a clearing response compared with myosin *B* or myofibrils. This tendency becomes

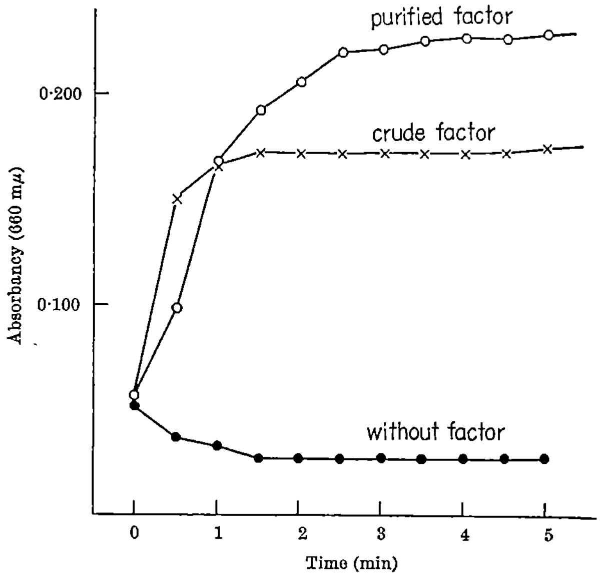

Fig. 1. Effect of contraction-promoting factor on the response of synthetic actomyosin to ATP. Procedures for superprecipitation experiments were essentially the same as already described (ref. 3). Ingredients of the reaction mixtures in final concentrations: 0·8 mg/ml. of synthetic actomyosin, 0·16 mg/ml. of 'crude extract' (ref. 2), 0·24 mg/ml. of purified factor, 0·02 M KCl, 1 mM $MgCl_2$, 1 mM ATP and 0·02 M *tris*-maleate (*p*H 6·8). Actin was obtained from exhaustively washed muscle residue and did not contain a significant amount of the factor

more pronounced when we use specially prepared actin which is free from the new protein mentioned here. As shown in Fig. 1 actomyosin thus prepared shows mainly only clearing response to a moderate concentration of ATP, namely, 1 mM. When the 'crude extract' of muscle residue obtained by the method for the preparation of 'native tropomyosin' is added to the actomyosin preparation, an instantaneous onset of superprecipitation is observed. This actomyosin shows rapid superprecipitation in response to low concentrations of ATP, for example, 10^{-5} M. The function of the factor contained in the 'crude extract', therefore, seems to enlarge the range of ionic strength and ATP concentration in which actomyosin responds to ATP with superprecipitation. Purified 'native tropomyosin' did not show any of this effect. On the contrary, it has rather depressing effect on superprecipitation. Therefore, the 'crude extract' should contain another factor which promotes the contraction of pure actomyosin.

Purification of the factor was performed chiefly by ammonium sulphate fractionation. It was first precipitated by 36 per cent saturation and then, after dissolving in water, by 21 per cent saturation. The protein thus obtained was fairly homogeneous according to the ultracentrifugation diagram. It showed an increasing tendency of aggregating with the elevation of ionic strength; without salt its $S_{20,w}$ was about 10, but more than 40 in 0·1 M potassium chloride. In spite of this remarkable aggregation its intrinsic viscosity remained low, less than 0·2, indicating the formation of a rather random aggregate, and not of end-to-end polymer, as in the case of denaturated actin[4]. Its amino-acid composition was similar to that of actin, and it did not contain any nucleotides. However, any actin preparations, native as well as denaturated, did not function like the new protein. Hence, the protein is now considered to be a new component in contractile elements. The yield of the protein was about 1 g from 100 g of muscle. If we take the loss during preparation into consideration, this amount may fairly correspond to that of actin.

If this contraction-promoting factor was added to *G*-actin, no change in its physical properties took place. However, on addition of salt, the polymerization process of actin was speeded up by the presence of the protein when it was followed by viscosimetry or flow birefringence measurements. On the other hand, no significant interaction could be observed between myosin and the new protein. Thus the new factor appears to act mainly on the *F*-actin moiety of actomyosin. Usual actin preparations contain this component in a varied amount. Therefore, it is possible that some of the properties so far ascribed to *F*-actin might be due to the influence of the new component on actin.

This protein probably plays an important part in contraction of living muscle in which ionic strength and ATP concentration are much higher than those of *in vitro* experiments. In this respect the protein may be regarded as the second protein factor, next to 'native tropomyosin'[1,2], regulating the myosin–actin–ATP interaction. In addition another protein influencing the physical state of *F*-actin has been isolated from myofibrils[5]. To understand the mechanism of muscular contraction in its entirety, we must clarify the mode of action of these natural regulators in detail.

DNA Polymerase in Thymus Nuclear Fractions isolated with Ca^{++}

Bollum and Potter[1] reported the incorporation of tritiated thymidine into DNA by enzymes present in a soluble high-speed supernatant fraction of aqueous homogenates of regenerating liver and of rat thymus. These enzyme activities were compared in nuclear and cytoplasmic aqueous extracts from Ehrlich ascites tumour cells by Smellie, Keir and Davidson[2] and by Smellie and Eason[3], who found them to be higher in the cytoplasmic fractions. In view of the paradox thus arising from the concept of synthesis of a nuclear component, DNA, by an enzyme apparently present in the cytoplasmic fraction, Keir, Smellie and Siebert[4] re-investigated this problem with revised assay techniques. They found DNA polymerase (DNA nucleotidyltransferase) activity higher in nuclei than in cytoplasm when these were isolated in non-aqueous solvents. Behki and Schneider[5] have reported similar findings in regenerating liver and Novikoff hepatoma nuclei isolated with non-aqueous solvents.

It is the purpose of this communication to present evidence for the presence of DNA polymerase in cellular particulate matter, that is, nuclear fractions of rat thymocytes when extracted with aqueous solvents, as well as the effect of Ca^{++} when included in these aqueous extraction media.

Sprague–Dawley 5½-weeks-old female rats from the animal colony of this laboratory were the source of thymus tissue. The *tris* (*tris*-hydroxymethyl-aminomethane), adenosine triphosphate and the deoxynucleoside triphosphates of adenine, guanine and cytosine were obtained from Sigma Chemical Co. The tritiated thymidine triphosphate, prepared enzymatically from tritiated thymidine (New England Nuclear Corp.), isolated and purified by the method of Lehman, Bessman, Simms and Kornberg[6], was the gift of Dr. E. R. Walwick.

Suitable portions of randomly pooled rat thymus tissue were homogenized with 9 vols. (ratio, 1·00 g tissue : 9·0 ml. buffer) of ice-cold *tris*-Cl (*tris*, 11·0 mM; *p*H 7·7) buffer solutions containing calcium chloride in concentrations shown in Table 1. The homogenates were centrifuged (105,000*g*; 1 h; 1° C) and a part of the clear middle portion of the supernatant fraction was taken for analysis (supernatant fractions *A*, Table 1). The first residue (pellet) fractions obtained were each drained, weighed and homogenized in *tris*-Cl buffer as already indicated, but with no Ca^{++}. Afterwards, all residue fractions were alternately frozen (−196° C) and thawed (2° C) three times, followed by homogenization. The supernatant extracts (centrifugation 105,000*g*; 1 h; 1° C) from the respective first residue fractions were designated 'extracts of first frozen residues' (Table 1, extracts *B*). By repetition of the foregoing process, 'extracts of second frozen residues' (Table 1, extracts *C*) and 'extracts of third frozen residues' (Table 1, extracts *D*), respectively, were obtained.

Each extract was dialysed by the method of Walwick and Main[7] to remove diffusible metabolites and Ca^{++}, assayed for protein concentration by the method of Lowry *et al.*[8], and stored frozen at −196° C until tested for DNA polymerase activity by the modified liquid scintillation counting methods of Main and Walwick[9] and Walwick and Main[7]. In this communication, DNA polymerase activity was determined by measuring the rate of incorporation of tritiated thymidine triphosphate (^{3}H-TTP) into DNA in the presence of the deoxyribonucleoside-5′-triphosphates of adenine, guanine and cytosine under the conditions indicated in Table 1.

When DNA polymerase was extracted from rat thymus cell homogenates by a low ionic strength *tris*-Cl (*tris* hydroxymethyl aminomethane) homogenization medium considerable DNA polymerase remained in the particulate pellet (Table 1, column 6). Thus, additional polymerase could be extracted following rehomogenization, freeze–thawing 3 times, and further homogenization of the pellet. Supplemental polymerase then could be obtained by second and third applications of the above process. These data also indicate that the percentage of total DNA-polymerase extracted from the pellet initially prepared in 2 mM Ca^{++} is more than twice that from the pellet initially prepared in the absence of Ca^{++}. In a second experiment in which the *tris*-Cl homogenization medium was made iso-osmolar (0·25 M) with respect to sucrose, results similar to those above were obtained following triple freeze–thaw extraction of the pellet (Table 2, column 7). Furthermore, in both experiments, as the Ca^{++} concentration of the initial homogenization medium was increased, the amount of polymerase later extracted from the initial pellet increased. One should note the approximately two-fold greater specific activity of DNA-polymerase in the first soluble supernatant extracts prepared in the *tris*-Cl buffer (no sucrose), as compared with corresponding values obtained in the presence of 0·25 M sucrose in the medium.

It is evident from these data that the partition of DNA-polymerase activity between the high-speed supernatant fraction and the centrifugal sediment, particulate fraction of rat thymus homogenates is dependent on the nature of the aqueous homogenization medium used, that is, whether or not it is iso-osmolar, and particularly on the Ca^{++} ion concentration. When Ca^{++} was varied from 0·0 to 6·0 mM a maximal localization of polymerase in the sediment was observed at 2 mM Ca^{++}. This calcium concentration appears to be specially significant, since it is also close to the value (1·8 mM Ca^{++}) found best suited for isolation, in aqueous sucrose medium, of morphologically intact mouse spleen nuclei by Schneider and Petermann[10], and of rat liver nuclei by Hogeboom *et al.*[11]. It is known that calcium ion precipitates the nuclear deoxyribonucleoprotein (DNP) complex[12,13]. The present results indicate that association of DNA-polymerase with the particulate nuclear sediment of thymus homogenates is favoured when the Ca^{++} concentration of the original homogenization medium is 2·0 mM or greater. It may be suggested from these findings that, in intact cells, DNA-polymerase is localized in the nucleus, perhaps in a labile association with DNP. It is of interest that Billen[14] has presented evidence for the association of DNA-polymerase as a complex with DNA in *E. coli* cells. Mazia and Hinegardner[15] found DNA polymerase activity in sea urchin embryos to be associated exclusively with nuclei when the latter were isolated in 1·2 M sucrose in the presence of either 1·0 mM Mg^{++} or 1·0 mM Ca^{++}. These were the only conditions found so far in which the polymerase activity was retained with nuclear material. Our results also suggest that when thymus tissue homogenates are prepared in low ionic strength iso-osmolar aqueous media in the absence of added Ca^{++} the DNP tends to become hydrated and dispersed (column 4, Table 2), and the associated DNA-polymerase is released into the aqueous phase.

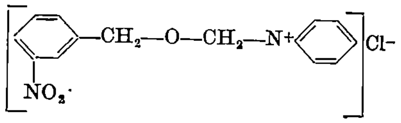
Use of Antibodies on an Insoluble Support for Specific Detection of Radioactive Antigens

When investigating the biosynthesis of different proteins and other compounds it appears to be necessary to isolate them from complex mixtures in order to measure radioactivity. The method of co-precipitation is often used, but it is somewhat limited. We tried to develop a new method for detecting radioactive antigens free of these limitations.

The method proposed is based on the use of immunosorbents (firm complex of soluble antigen with insoluble support) in the form of a suspension able to combine as much as 0·3–1·0 g antibodies to 1 g (dry weight) sorbent[1]. We used such sorbent-antigens for the isolation of pure antibodies and for the quantitative detection of antibodies by measuring the increase in protein or radioactivity on sorbent-antigens[2–4]. The principle of this method rests on the fact that bivalent antibody is combined with the antigen on insoluble support by means of one combining site while the other combining site is free and thus capable of reacting with a soluble homologous antigen.

Such a complex can be used for the isolation of corresponding antigens from the solution. The principal potentiality of this reaction has already been demonstrated[5].

The method of preparation of sorbent-antigens in the form of suspension has already been described[1]. It consists in treating, at 125° C, the cellulose with the following pyridinium salt:



to introduce the organic residue.

After reducing the nitro group to an amino group the product is dissolved in Schweizer's reagent. Cellulose in a form of suspension precipitated after this solution was diluted with large amounts of water was diazotized and coupled to the desired antigen. We used human serum albumin (HSA) and horse γ-globulin (HGG). Complexes capable of combining with antigens (sorbent-antibody) were prepared by adding immune serum containing antibodies corresponding to the sorbent-antigen. The mixture was stirred for 10 min at room temperature and washed three times with 0·85 per cent sodium chloride at *p*H 7 from unbound proteins by centrifugation.

The amount of antibodies needed to obtain active preparation must not be less than the amount able to saturate half the combining capacity of the sorbent-antigen.

HGG fixed with cellulose (C-HGG) treated with corresponding antibodies (C-HGG : anti-HGG) was used in the majority of our experiments. Cellulose-HSA (C-HSA) and C-HGG treated with normal rabbit serum, and C-HSA treated with corresponding antibodies (C-HSA : anti-HSA) served as control preparations.

1 ml. (1·5–3·0 mg dry weight) of one of the control preparations was put into little centrifuge tubes and 2 ml. of the solution containing different amounts of HGG labelled with iodine-131 (ref. 6) were added in different experiments. After stirring for 10 min at room temperature the sediment (sorbent) was separated by centrifugation (5,000 r.p.m.) and supernatant was transferred into the centrifuge tubes which contained the same amounts of sorbent-antibody as in the control. After stirring, the sorbent was separated by centrifugation. The sediments obtained were quantitatively transferred to chromatographic paper (Whatman No. 1) disks (diam. = 20 mm) to make a spot about 10 mm in diameter. To wash out the unbound label these disks were placed in an apparatus for descending chromatography on a sheet of paper (Whatman No. 1). One end of this sheet of paper was placed in the trough containing 0·5 per cent potassium iodine in 0·85 per cent sodium chloride (*p*H 7). This procedure was introduced to detect carbon-14 antibodies by measuring the specific increase in activity of carbon-14 on the sorbent antigen[3,4]. The next day the disks were dried for 15 min at 60° C and then their radioactivity was measured. The results obtained are given in Table 1, which shows that HGG–^{131}I is specifically adsorbed by the sorbent contained anti HGG. Non-specific adsorption does not exceed 3 per cent from specific.

Table 1

Exp. No.	Sorbents		Treated with rabbit serum					Added HGG–^{131}I		All added ^{131}I activity (c.p.m.)	Combined ^{131}I activity c.p.m. sample	Increase in ^{131}I activity on sorbent-antibody (c.p.m.)
	Name	Amount (mg)	Normal	Contained antibodies against HGG		Contained antibodies against HSA		µg	Specific activity (c.p.m.)			
			Volume (ml.)	Volume (ml.)	Antibody protein (µg)	Volume (ml.)	Antibody protein (µg)					
40	C–HGG	1·5	0·63	—	—	—	—	7·5	106	795	23	710
	C–HGG	1·5	—	0·63	540						733	
45	C–HSA	1·5	0·15	—	—	—	—	20	41	810	25	14
	C–HSA	1·5	—	—	—	0·15	300				39	
	C–HGG	1·5	0·15	—	—	—	—	20	41	810	33	577
	C–HGG	1·5	—	0·15	300	—	—				610	

Experiments with the tracer dilution when adding non-radioactive HGG and experiments on measuring absolute increase in protein when being added to a sorbent-antibody showed the combining capacity of the preparations used is 30–50 mg of antigens on 1 g of sorbent-antibody.

Further experiments showed those antigens which are specifically adsorbed by the sorbent antibody keep the capacity to react with corresponding antibodies from the solution added: this was proved by means of ^{14}C-antibodies. Sorbent antibody also appeared to be capable of reacting not only with antigens but also with soluble antigen–antibody complex; it allows presence of radioactive antibodies masked by excess of antigen in the system to be revealed.

The data obtained testify to the possibility of the following reactions between antigens (*Ag*) and antibodies (*Ab*).

$$\begin{array}{ll}
1 & \underset{\text{sorbent-antigen}}{C - Ag} + Ab = \underset{\text{sorbent-antibody}}{C - Ag : Ab} \\
2 & C - Ag : Ab + Ag = C - Ag : Ab : Ag \\
3 & C - Ag : Ab : Ag + Ab = C - Ag : Ab : Ag : Ab \\
4 & C - Ag : Ab + \underset{\text{soluble antigen–antibody complex}}{Ag : Ab} = C - Ag : Ab : Ag : Ab
\end{array}$$

The method described here can be used for the detection of different radioactive antigens. At rather high specific activity one can reveal as much as 0·01–0·001 μg of radioactive antigens. This has certain advantages over that of co-precipitation since it can be applied not only to precipitating but also to non-precipitating systems. Another advantage is low non-specific adsorption and small labour consumption.

Effect of the Unsaturated Bond on the Degradation of the Tetragalacturonic Acids by a Transeliminase

During the course of investigations of the degradation of the normal and unsaturated-tetragalacturonic acids by a transeliminase[1,2], it was found that unsaturated tetragalacturonic acid was attacked about 1·4 times faster than the normal tetramer. Furthermore, it was observed that the unsaturated tetramer must be almost completely converted to unsaturated digalacturonic acid since there was an approximate doubling (96 per cent increase) in the optical density. All activities were determined by measuring the change in optical density at 232 mμ. Unsaturated galacturonic acid does not absorb at this wave-length, presumably because of isomerization to the keto-deoxy derivative[3]. The observation with unsaturated tetragalacturonic acid was confirmed with the aid of paper chromatography using the ethyl acetate–pyridine–water–acetic acid solvent[1]. Only a spot with an R_F identical to unsaturated digalacturonic acid was detected.

As indicated in a previous publication[1], tetragalacturonic acid is attacked at the two glycosidic linkages farthest from the reducing end (designated bonds 2 and 3; bond 1 being that nearest the reducing group). That bond 1 is not attacked was shown by the complete absence of normal trigalacturonic acid. The relative rates of attack of the two bonds can be determined by comparing the amounts of normal galacturonic acid and normal digalacturonic acid produced since the latter arises only from attack at bond 2 and the former by attack at bond 3. Thus a sample of a 24-h reaction mixture was spotted on paper, developed with the previously mentioned solvent system, the strips cut out and eluted with water. The amount of uronide material was determined in each sample by the carbazole method[4]. In this manner it was determined that bond 3 was attacked about 1·4 times faster than bond 2. All the above results were reproducible.

Since the total cleavage of glycosidic linkages in tetragalacturonic acid is the sum of attack at bonds 2 and 3, it was concluded that the central glycosidic linkage of unsaturated tetragalacturonic acid was attacked about 3·4 times faster than was bond 2 of normal tetragalacturonic acid. Thus if one accepts the previous conclusion that only one enzyme is excreted by *Bacillus polymyxa*[5] one must conclude that the presence of the unsaturated bond somehow inhibits attack at bond 3 but enhances the rate of degradation of bond 2. Whether this is due to the change in configuration of the unsaturated unit (planar) or to other effects has yet to be determined.

Paper Electrophoresis of Soluble Lens Proteins in Lactose-fed Rats

Proteins of the lens tissue of the eye have been extensively examined because of their relationship with cataract formation. In all forms of cataract a decrease was found in the total amount of lens proteins as compared with normal lens of the same age[1]. Changes in the proportion of the soluble proteins of the lens measured by electrophoresis have been reported in different kinds of cataract; but, according to van Heyningen[2], no consistent patterns have emerged from these investigations. The work recorded here was carried out to determine the behaviour on paper electrophoresis of soluble lens proteins of the rat, as well as the possible changes in the proportion of the different fractions during lactose feeding.

Albino rats, weighing 70–80 g at the beginning of the experiment, were given a 40 per cent lactose diet, and the controls a 40 per cent cane sugar diet, as already described[3]. At appropriate intervals, the animals were killed and the lens homogenate prepared as already described[3]. Paper electrophoresis was performed with a volume of the supernatant of centrifuged lens homogenate, containing 1–1·5 mg of soluble lens proteins. A borate buffer (0·05 M, *p*H 8·6) was used; the potential gradient of electric field was of 5 V/cm for 10 h. The paper strips were stained with bromophenol blue, and the different fractions measured by densitometry.

The soluble lens proteins of normal and lactose-fed animals, separated by means of this method, gave four distinct moieties (Fig. 1), which will be labelled I, II, III and IV, fraction I being the most rapid one. After two months of lactose feeding, it was possible to observe (Table 1) an increase of fraction I (the most rapid one), and

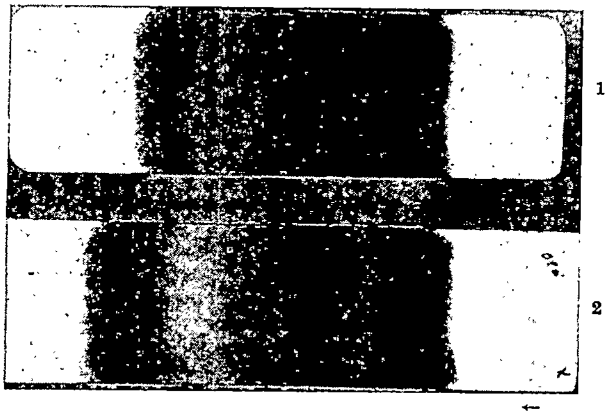

Fig. 1. Paper electrophoresis of soluble lens proteins. 1, Normal rat; 2, lactose-fed rat (2 months)

a decrease of fraction IV (the slowest). These changes occurred in all animals examined. The difference between the mean value of normal and lactose-fed animals, for fractions I and IV, is very significant ($P < 0.001$), which is by no means the case for fractions II and III.

In order to ascertain the progressive changes in the proportions of electrophoretically separated proteins, another group of rats was maintained on the same 40 per cent lactose diet, three rats being killed at different intervals. The first three animals were killed before the lactose diet was started. As shown in Fig. 2, after feeding for 5 days fraction I begins to increase and fraction IV to decrease, but during the first month the values found were within the normal range. After this period, this phenomenon was very conspicuous, and also fractions II and III started to increase, but in a lesser degree than fraction I.

As observable, our results indicate that even using a mild lactose diet, intended to obtain slower changes in the biochemistry of the lens, early changes in the pattern of soluble lens proteins are found in rat lenses. It has been reported that the electrophoretically most rapid fraction corresponds to the α crystallin[4], while all the other fractions may correspond to the β- (and γ-) crystallin[2]. It has been stated that there is a loss of β-crystallin in different types of cataracts[2]. The decrease of fraction IV found in this investigation may correspond to the fall of β-crystallin observed with other methods. The increase of fraction I suggests that there is an increase of α-crystallin.

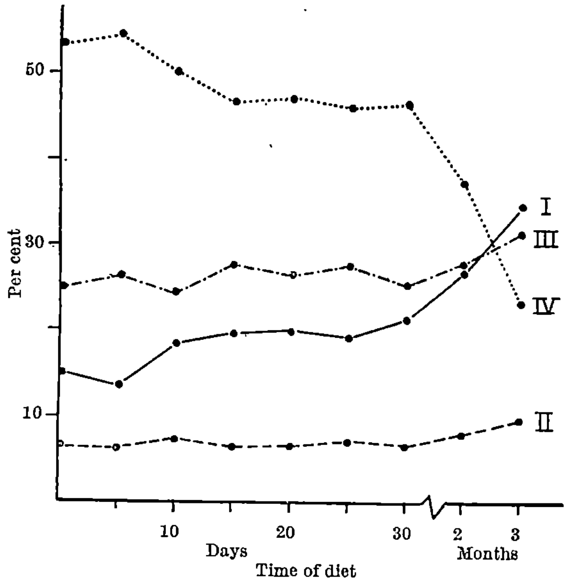

Fig. 2. Paper electrophoresis fractionation of soluble lens proteins in lactose-fed rats at different periods. On each day indicated 3 animals were killed and the stated amounts are the mean values of the three determinations

Table 1. Paper Electrophoresis of Soluble Lens Proteins in Normal and Lactose-fed Rats

	Fraction I	Fraction II	Fraction III	Fraction IV
Normal diet No. of animals, 14	17·7 ± 2·7	7·6 ± 1·3	26·2 ± 2·7	48·5 ± 2·5
Lactose diet No. of animals, 14	27·0 ± 2·2	8·0 ± 1·8	27·8 ± 2·2	37·2 ± 4·0
P	< 0·001	> 0·5	> 0·1	< 0·001

Animals were given lactose diet for 2 months.
All values are given in percentages of the total amount of soluble proteins ± *S.D.*

In cataracts of galactose-fed rats, François *et al.*[5] have found a loss of soluble proteins. With a higher proportion of lactose in the diet as used in this experiment, we found an early fall of the soluble lens proteins[6]; but during this mild lactose diet the amount of total soluble proteins does not decrease until the fortieth day of feeding[7]. Hence, the protein pattern of the lens begins to change before the total amount of soluble proteins starts to decrease.

Adrenal Glands in Vitamin E Deficiency: *in vitro* Corticoid Synthesis by Quartered Adrenal Glands of Rats deprived of Vitamin E

Recent investigations in this laboratory have indicated an inhibition of corticosterone synthesis in quartered adrenal glands from vitamin E-deficient rats[1]. It was also found that adrenal homogenates of the deficient rats, when properly diluted, undergo *in vitro* lipid peroxidation and formation of malonaldehyde, as determined by the thiobarbituric acid (TBA) test, more readily than any other organ tested[1,2]. However, when incubated adrenal quarters instead of homogenates were assayed for lipid peroxidation by the TBA method, there was very little net production of malonaldehyde, but significant inhibition in corticoid synthesis occurred in the quartered adrenals of vitamin E-deficient rats. This is in contrast to other enzymatic inhibitions which have been demonstrated in vitamin E-deficient rats and shown to be associated with the process of *in vitro* lipid peroxidation[3,4]. The various investigations and aspects of *in vitro* lipid peroxidation in adrenal homogenates of vitamin E-deficient rats will be reported separately. This communication reports preliminary data obtained on corticoid synthesis by the quartered adrenal glands of vitamin E-deficient and sufficient rats.

Diets, the procedures for the handling of rats, and determination of malonaldehyde are modifications of the previous procedure[3]. The animals were fed the diet *ad libitum* for 11–55 days. Corticoid synthesis was examined in two types of experiments: experiment *A* (Table 1) consisted of incubation of adrenal quarters without previous preincubation; experiment *B* (Table 2) consisted of procedures of Saffran and Schally[5] with preincubation of the tissue in isotonic salt medium[6], followed

Table 1. *In vitro* CORTICOID SYNTHESIS BY QUARTERED ADRENAL GLANDS OF VITAMIN E-DEFICIENT RATS AND THEIR CONTROLS

Incubation medium	Prep. of vit. E-def.		Prep. of vit. E-suff.	
	Corticosterone (μg/10 mg/h)	Malonaldehyde *O.D.* 530 mμ	Corticosterone (μg/10 mg/h)	Malonaldehyde *O.D.* 530 mμ
Krebs–Ringer (13)*	0·529 ± 0·142	0·00	0·579 ± 0·114	0·00
Rat serum (22)*	1·360 ± 0·260	0·00	2·380 ± 0·290	0·01

* Numbers in parentheses indicate total number of animals used in each experiment. ± Standard error of mean.

Adrenal quarters were incubated in 1 ml. of serum or 1 ml. of Krebs–Ringer–bicarbonate–glucose for 1 h at 37° C. At the end of incubation time 0·25 ml. aliquots removed and diluted with ethanol to final concentration of 13 per cent and frozen immediately for later assay of corticosterone. Another 0·25 ml. aliquot was removed for malonaldehyde assay.

Table 2. *In vitro* CORTICOID SYNTHESIS AND MALONALDEHYDE FORMATION BY QUARTERED ADRENAL GLANDS OF VITAMIN E-DEFICIENT RATS AND THEIR CONTROLS

Portion of test system assayed	Prep. of vit. E-def.		Prep. of vit. E-suff.	
	Corticosterone (μg/10 mg/h)	Malonaldehyde *O.D.* 530 mμ	Corticosterone (μg/10 mg/h)	Malonaldehyde *O.D.* 530 mμ
(*a*) Medium at end of pre-incubation period	0·224	0·000	0·783	0·000
(*b*) Medium at end of incubation period	0·237	0·043	0·545	0·063
(*c*) Adrenal glands at end of incubation period	0·437	0·000	0·602	0·016

Adrenal quarters equivalent to two adrenal glands from two rats were pooled and preincubated in 2 ml. of isotonic salt medium in Dubnoff shaker for 1 h. At the end of the period the mixture was removed and aliquots brought to final concentration of 13 per cent ethanol and quickly frozen. Fresh medium consisting of 2 ml. serum of rat in each dietary group was added to the adrenals, incubated for 1 h in Dubnoff shaker at 37° C. The values have been corrected for endogenous and blank values of the medium.

by incubation of the tissues in the serum of the same rat. The incubation media in experiment *A* consisted of either Krebs–Ringer–bicarbonate–glucose solution or rat serum, while in experiment *B* the incubation medium consisted of serum only. The gas phase in all the experiments consisted of 95 per cent oxygen and 5 per cent carbon dioxide, and equilibration was achieved in either Warburg vessels (exp. *A*) or in a small beaker placed in a Dubnoff shaker, fitted with a gassing hood (exp. *B*). The incubation time was 1 h at 37° C.

Since the major steroid secreted by the rat adrenal gland preparation is corticosterone[7], its synthesis was assayed by the fluorometric method of Silber *et al.*[8]. Assays were performed on 0·25-ml. aliquots of the incubation medium.

Further evidence demonstrating that the corticoid synthesized in these experiments was corticosterone was obtained by the following procedure: the incubation medium was extracted with methylene chloride and dried under reduced pressure. The residue was taken up in small amounts of ethylacetate and was subjected to thin-layer chromatography[9,10]. The corticoid formed in exp. *A* (Table 1) was chromatographically identical with corticosterone. There also were other polar steroids in the medium which have not yet been identified.

The data in Table 1 indicate that corticoid synthesis *in vitro* by adrenal gland quarters incubated in serum is about 43 per cent less in the deficient group than in the controls. However, the corticoid synthesis was not significantly different in the two dietary groups when the synthetic medium was used instead of serum. Furthermore, the total corticoid synthesis in the synthetic medium was only 1/4 or 1/3 of the serum-incubated glands in both groups of rats. Results shown in Table 2 also indicate that the difference in corticosterone synthesis is also evident when adrenals are pre-incubated before incubation in the serum.

Lipid peroxidation and malonaldehyde formation between the two dietary groups of rats were not significantly different in any of the experiments with quartered adrenal glands. This is in contrast to the results obtained with the adrenal homogenates, in which case large amounts of malonaldehyde are formed in preparations from vitamin E-deficient rats[1,2]. As shown in Table 2, malonaldehyde does not accumulate in the quartered glands (Table 2*c*), nor is it secreted into the media since none of the media tested showed significant net production of this substance (Table 2*a* and *b*). Unlike two other enzyme systems which are inhibited *in vitro* in vitamin E-deficient rats[3,4], the inhibition of corticosterone synthesis under these experimental conditions may not be related to process of lipid peroxidation as measured by malonaldehyde production, and hence, sufficiency of tocopherol in the rat may be directly involved in corticoid synthesis in these experiments.

In vivo determination of corticosterone by the method of Silber *et al.*[8] in the serum and the adrenal tissues of the vitamin E-deficient rats and their controls demonstrated 0·348 and 0·354 μg of corticosterone per ml. of serum of deficient and sufficient rats respectively while the level of corticosterone in the adrenals in 9 pairs of rats was 0·214 and 0·334 μg per 10 mg of tissue in vitamin E-deficient and sufficient rats respectively. The corticosterone level of the adrenals in the deficient rat is significantly 34 per cent less than the control group, but the serum level shows no difference in the two dietary groups.

The *in vitro* addition of tocopherol to the incubation medium for the quartered glands failed to reverse the inhibition of corticoid synthesis in three instances tried.

I thank Drs. P. B. McCay and R. Caputto for their advice.

PHYSIOLOGY

New Motor End-plates and their Relationship to Muscle Fibre Injury

IT has been shown by Guth and Zalewski[1], Hofmann *et al.*[2], Koenig[3] and Miledi[4] that new motor end-plates will form in denervated skeletal muscle or muscle devoid of its original motor end-plates in mammals and amphibians following implantation of a motor nerve. However, in all these experiments the muscle suffered considerable damage, either during implantation of the nerve or in transecting the muscle to remove the original motor end-plate zone.

When an accessory nerve is implanted into the transected surface of a muscle in which the innervation and original motor end-plate zone are intact, then new motor end-plates will form on the muscle fibres near the cut margin of the muscle[4]. It appears, therefore, that injury to the muscle fibres is a major factor in the causation of these new motor end-plates. However, it has not yet been shown whether nerve fibres can produce new motor end-plates on muscle fibres that have been denervated but not mechanically injured.

The peroneal nerve in rats was cut and laid on the surface of tibialis anterior muscle at its proximal (end-plate free) zone, having first carefully incised the fascia over the superficial surface of the muscle. The nerve was held in place with a small amount of clotted fibrin.

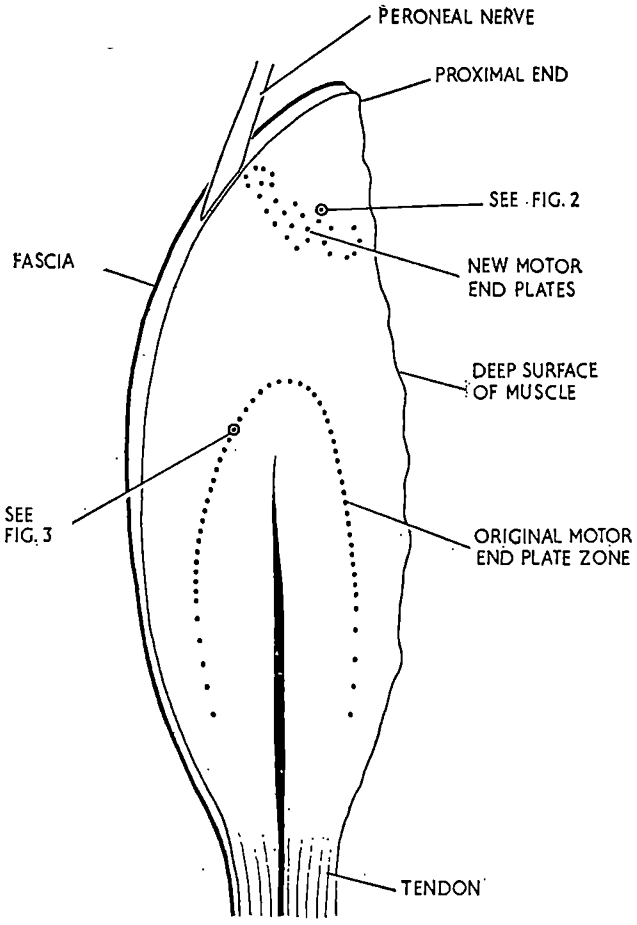

Fig. 1. Diagrammatic radial section of tibialis anterior muscle of rat showing position in which the peroneal nerve is laid on the muscle and also the new and original motor end-plate zones

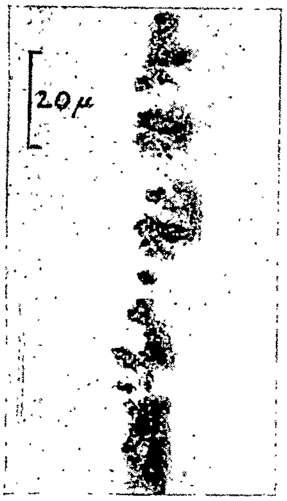

Fig. 2

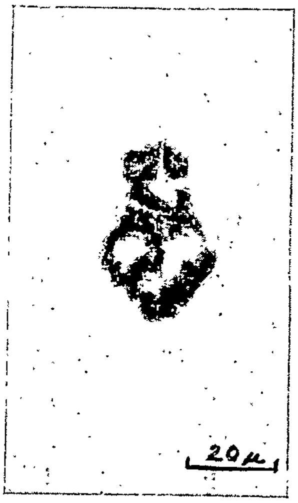

Fig. 3

Fig. 2. New motor end-plate stained by the cholinesterase method 63 days following 're-innervation'

Fig. 3. Original motor end-plate from the same section as Fig. 2 stained by the same method, showing marked degenerative changes

As early as 35 days after 're-innervation' the muscle responded to stimulation of the nerve. Modified Koelle and Friedenwald cholinesterase staining showed deposits of copper sulphide on muscle fibres in the upper region of the muscle, which is normally free of motor end-plates. By counterstaining with silver nitrate, nerves could be followed into these deposits. Silver staining alone showed new motor end-plates in the upper region of the muscle, but the nerves had not re-innervated the end-plates in the original end-plate zone. The new motor end-plates found in the proximal part of the muscle were not restricted to the immediate vicinity of the superficial region of the muscle but had spread to the deeper muscle fibres in the zone (Fig. 1).

Thus while mechanical injury to the muscle fibres may in some cases be a factor in the production of new motor end-plates, it is almost certainly not a necessary factor. Although the most superficial muscle fibres might possibly have been injured in the laying on of the nerve or by some osmotic effect of the fibrin, the more deeply placed ones must have remained intact.

The new motor end-plates are formed on these deeply placed muscle fibres as well as on the more superficial ones.

The main factor in the production of these new motor end-plates in mammalian skeletal muscle would appear to be the availability of denervated muscle fibres and not mechanical injury to the muscle.

Nicotinic and Muscarinic Receptors of Renshaw Cells

The method of electrophoretic ejection from multi-barrel micropipettes, in conjunction with the recording of electrical responses from single neurones[1], provides a unique opportunity for classifying central acetylcholine receptors according to their pharmacological properties. It has been usual to subdivide these receptors into nicotinic and muscarinic types, a classification based on the original use of these terms by Dale[2] to describe the peripheral actions of certain derivatives of choline. The following evidence has suggested that the receptors of Betz cells are muscarinic[3]: nicotine is a weak excitant; acetyl-β-methylcholine and *dl*-muscarine are almost as active as acetylcholine; the excitation by acetylcholine is slow in onset and is readily blocked by atropine but not by dihydro-β-erythroidine. In contrast the acetylcholine receptors of Renshaw cells exhibit nicotinic properties[4]: nicotine is a more powerful excitant than acetylcholine; acetyl-β-methylcholine and *dl*-muscarine are very weak; the excitation by acetylcholine is rapid in action and is readily blocked by dihydro-β-erythroidine but not by atropine. The acetylcholine sensitivities of ventrobasal thalamic neurones, and of cerebellar neurones, are of intermediate types[5].

Spinal cats anæsthetized with pentobarbital were used in the investigation reported here on the acetylcholine receptors of Renshaw cells in the lumbar spinal cord[4]. Cholinomimetics and blocking agents were administered either electrophoretically from multibarrel glass micropipettes or by intravenous injection. The cells were excited synaptically by stimulation of the central end of the appropriate ventral root. As illustrated in Fig. 1*A*, acetyl-β-methylcholine was much slower in time course as an excitant of these neurones and was less effective than acetylcholine. Concentrations of dihydro-β-erythroidine which very effectively depressed the firing produced by acetylcholine (Fig. 1*B*) did not reduce the action of acetyl-β-methylcholine. With other cells it proved possible to suppress completely the action of nicotine without diminishing the excitant effect of acetyl-β-methylcholine. Simultaneously the characteristic repetitive and high-frequency synaptic response of Renshaw cells, of duration 20–60 msec (ref. 4), was reduced to one or two spikes.

On the other hand, after the intravenous administration of atropine sulphate (0·1 mg/kg) the response evoked by acetyl-β-methylcholine was reduced to a much greater extent than that to acetylcholine (Fig. 1*C*). Doses of atropine sulphate as high as 0·5–2 mg/kg completely blocked the action of acetyl-β-methylcholine, but were found to diminish the effectiveness of acetylcholine only by about 40 per cent. Such doses have little action on the synaptic response, which is dihydro-β-erythroidine sensitive[4], but have been observed to depress a previously described late response which follows this high-frequency firing[6].

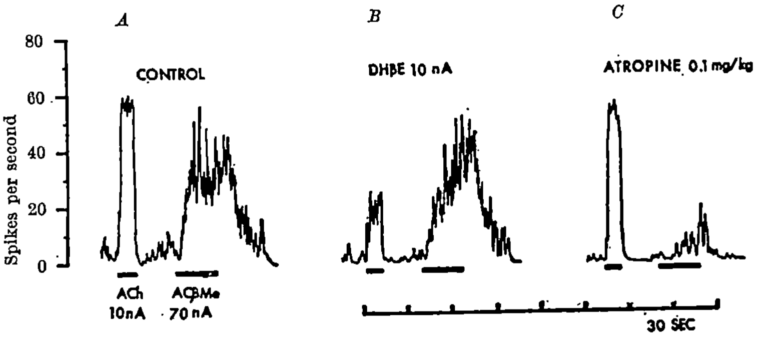

Fig. 1. Frequency of firing of a Renshaw cell, plotted by means of a rate meter and paper recorder (see ref. 5), and produced by electrophoretic ejections of acetylcholine (ACh—10 n.amp) and acetyl-β-methylcholine (ACβMe—70 n.amp), as indicated by the horizontal bars. *A*, control; *B*, during the ejection of dihydro-β-erythroidine (DHβE, 10 n.amp) from a 10 mM solution in 165 mM sodium chloride contained in another barrel of the micropipette. The responses recovered over the next 12 min. *C*, after intravenous injection of atropine sulphate 0·1 mg/kg. Time, 30 sec

The most satisfactory explanation of these results is that each Renshaw cell has two types of acetylcholine-sensitive receptors, both of which are concerned with excitation. The nicotinic receptors are readily blocked by dihydro-β-erythroidine and are presumably located beneath the synaptic terminals of axon collaterals. The muscarinic receptors are atropine sensitive and are apparently associated with a late synaptic response. This duality of acetylcholine receptor sites on a single cell has not been previously demonstrated.

In general the pharmacological properties of Renshaw cells[4] resemble those of neurones within autonomic ganglia, and the present findings lend support to the proposal that certain ganglion cells also have two types of postsynaptic acetylcholine-sensitive receptor[7]. The possibility that the individual cells of other cholinoceptive tissues also have two basic types of receptor may lead to a better understanding of the nature of such receptors, and to a simplification of certain aspects of the mode of action of acetylcholine, cholinomimetics, acetylcholine antagonists and anticholinesterases at and near synapses. Such considerations offer an explanation of the apparently mixed nicotinic-muscarinic properties of the receptors on certain central neurones[5].

Ionic Changes Responsible for Post-tetanic Hyperpolarization

After repetitive stimulation, the membrane potential of nerve fibres is transiently increased. It has been suggested by Ritchie and Straub[1] that this hyperpolarization could be explained on the basis of two assumptions: that the ionic pump responsible for the coupled efflux of sodium ions and influx of potassium ions[2] becomes hyperactive following stimulation because of the raised intracellular sodium ion concentration[3]; that the extracellular space adjacent to the membrane is confined by a diffusional barrier. Following activity, the hyperactive pump would deplete the potassium in this space and thus raise the membrane potential of the nerve fibre above its resting level. A consequence of this hypothesis is that, in the absence of extracellular potassium, the sodium pump would be unable to lower the potassium concentration further and there would be no post-tetanic hyperpolarization, as Ritchie and Straub[1] indeed found in mammalian *C*-fibres. On the other hand, an increased post-tetanic hyperpolarization in potassium-free solutions has since been reported both in the same fibres[4] and in frog nodes of Ranvier[5].

In the present investigation we have examined post-tetanic hyperpolarization of motor nerve terminals in the isolated rat diaphragm–phrenic nerve preparation under conditions of reduced and increased extracellular potassium concentrations. The results are of particular interest in that we have observed in potassium-free solutions both an increase and decrease in post-tetanic hyperpolarization depending on the exposure time.

The dissection of the preparation, the method of mounting, the composition of the bathing solution and the techniques of location of nerve terminals with a microelectrode have been already described[6]. Neuromuscular transmission was blocked either by raising the magnesium chloride concentration or by raising the magnesium chloride and lowering the calcium chloride concentration of the bathing medium. Individual nerve terminals were located with a microelectrode filled with 4 M sodium chloride with a 1–2μ tip by the recording of extracellular miniature endplate potentials[6]. Short (0·1 msec) cathodal stimulating pulses were then passed through the same electrode from a Grass stimulator. In response to the stimulation, repeated every second, small all-or-nothing antidromic potentials were recorded from the phrenic nerve through a pair of platinum electrodes. The stimulus strength was varied until, over a 60-sec period, 20–80 per cent of the stimuli failed to evoke a response. The phrenic nerve was then stimulated with a tetanus of 1,000 shocks at 100/sec through a proximal pair of platinum electrodes. Following this tetanus, the microelectrode stimulus was continued at the same strength and rate until the number of antidromic responses approximated to the pretetanic level. A rise in nerve threshold was detected by an increase in the number of failures to respond to stimulation and was interpreted as an effect of a raised membrane potential[7], that is, a post-tetanic hyperpolarization.

In Fig. 1*A* a typical control experiment is illustrated. The bathing medium contained 5 mM potassium chloride and before the tetanus 67 per cent of the stimuli failed to evoke an antidromic response (dotted line). After the tetanus (hatched bar) there was no response in the first five successive 10-sec periods (open circles) and the threshold as judged by this technique remained above the control value for some 70 sec. The bathing solution was then changed to one containing no added potassium

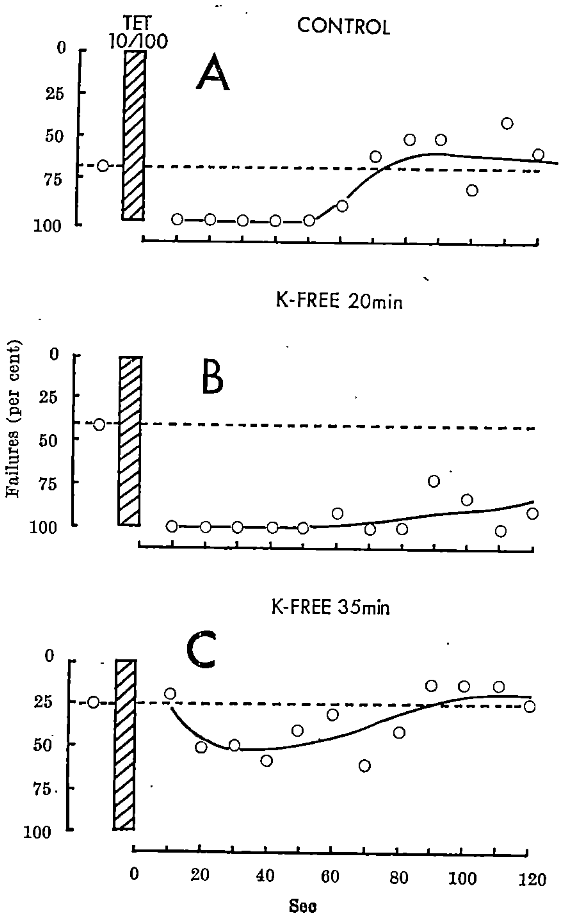

Fig. 1. The threshold of motor nerve terminals in the rat diaphragm *in vitro* after 1,000 orthodromic stimuli at 100/sec. The bathing solution contained 5 mM potassium chloride for the experiment illustrated in *A*, and this fluid was changed to a solution with no added potassium chloride ('K-free') for *B* and *C*. The ordinate indicates the percentage of stimuli at 1/sec which failed to evoke an antidromic response. The percentage was assessed over a 60-sec period before the tetanus, and this control level is shown by the dotted line in *A*, *B* and *C*. After the tetanus (hatched bar) the percentage (open circles) was calculated for successive 10-sec periods. In *A* there was a 70-sec period after the tetanus during which the percentage of failures was greater than the control-level. In *B* after 20 min in the 'K-free' solution this period was more than 120 sec. After 35 min (*C*) there was no change in threshold in the 10-sec period immediately after the tetanus. The bathing solution contained 6·5 mM magnesium chloride and 1 mM calcium chloride. The temperature was 36° ± 1° C

chloride. When the experiment was repeated (Fig. 1*B*) 20 min later, the post-tetanic hyperpolarization inferred from the raised threshold was markedly increased and prolonged, lasting more than 120 sec. After 35 min immersion (Fig. 1*C*) there was a dramatic reduction of the post-tetanic hyperpolarization. Indeed in the 10-sec period after the tetanus the number of responses was above the average for the control period (dotted line). At this stage, by observing extracellular end-plate potentials during an identical nerve tetanus, we established that the nerve impulses had reached the nerve terminals. Full recovery of post-tetanic hyperpolarization was seen when the preparation was again bathed in the control solution containing 5 mM potassium.

In several experiments, the potassium concentration of the bathing solution was raised to 15 mM—three times the control concentration. Invariably the normal hyperpolarization following a tetanus (Fig. 1*A*) was abolished and in fact was often replaced by a phase of depolarization. The abolition was fully reversible on washing with the control solution.

The early increase of post-tetanic hyperpolarization in potassium-free solutions (Fig. 1*B*) agrees with the results of Holmes[4] and Meves[5]. The later decrease in hyperpolarization is similar to the decrease reported by Ritchie and Straub[1]. These varied findings can be explained by the hypothesis put forward by Coombs, Eccles and Fatt[8] to explain after-hyperpolarization in motoneurones; namely, that in the nerve fibres an increased potassium conductance continues after the train of impulses so that the membrane potential approaches the potassium equilibrium potential. Because the contribution to the resting potential of other ions, such as sodium and chloride, cannot be ignored when the extracellular potassium concentration is near or less than the physiological concentration, the resting membrane potential is normally less than the potassium equilibrium potential. Following activity in the nerve we assume a prolonged increase in the permeability of the membrane to potassium ions so that the membrane potential moved closer to the potassium equilibrium potential, so causing a hyperpolarization (Fig. 1*A*). When the extracellular potassium concentration was greatly reduced in our experiments by omitting potassium chloride from the bathing solution, the potassium equilibrium potential would have increased with little increase in the resting membrane potential. Following a tetanus an increase in potassium conductance would then move the membrane potential towards this elevated potassium equilibrium potential, causing more hyperpolarization (Fig. 1*B*). The later reduction in hyperpolarization in the potassium-free solution (Fig. 1*C*) can be explained by the recognized action of a potassium-free solution in decreasing the intracellular potassium concentration[9]. The potassium equilibrium potential would, of course, fall commensurately with this fall in intracellular potassium concentration. Similarly, in solutions containing 15 mM potassium chloride the potassium equilibrium potential and membrane potential would be virtually the same. This would explain the reduction of post-tetanic hyperpolarization in these circumstances.

It is perhaps not unexpected that the same mechanism should be postulated to explain post-activation hyperpolarization in the somas[8], Ranvier nodes[5] and nerve terminals of motoneurones.

Potentials evoked in the Hypothalamus and Cerebral Cortex by Electrical Stimulation of the Uterus

After the 36th week of pregnancy, labour is readily initiated by such procedures as dilating the cervix, passing uterine bougies and, most effectively, by amniotomy. This ability to initiate labour by mechanical interference suggests the existence of nervous pathways from uterus to hypothalamus. The presence of appropriate receptors in the rabbit uterus has been demonstrated by Ferguson[1] and by Bower[2], but little is known of the central pathways involved. In the experiments recorded here on cats anæsthetized with chloralose we used the evoked potential technique to detect uterine afferent relays to the hypothalamus. Pairs of stainless steel stimulating electrodes were implanted into the myometrium, one pair high in one uterine horn and another pair below the level of fusion of the two horns, but above the vagina. The uterus was then subjected to direct electrical stimulation

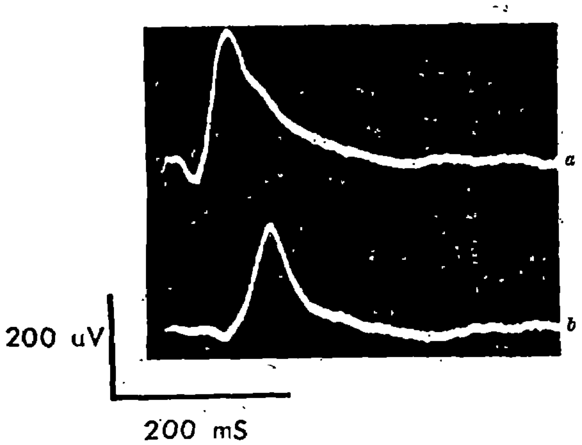

Fig. 1. Responses obtained at the same hypothalamic recording site in response to (*a*) electrical stimulation of the skin of one forepaw and (*b*) electrical stimulation of the myometrium of one uterine horn. Note that uterine stimulation is followed by an evoked potential of small amplitude and long latency

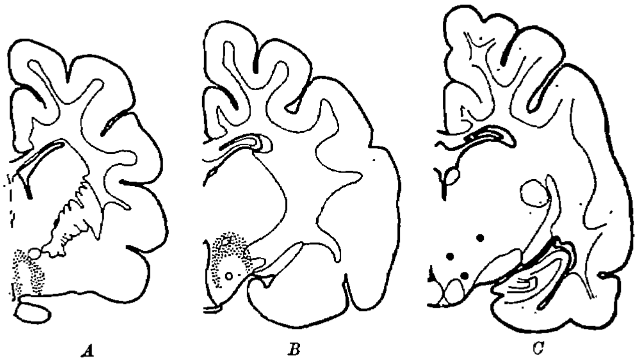

Fig. 2. Diagrammatic coronal sections of the cat brain to show the distribution of potentials evoked in the hypothalamus by electrical stimulation of the uterus. The stippled regions in sections *A* and *B* are those from which responses could consistently be elicited. The three large dots in section *C* indicate where responses were obtained on one occasion

through either pair of electrodes by square wave pulses of 1–3 msec duration.

Evoked potentials recorded from the hypothalamus of cats anæsthetized with chloralose show irregularities[3] due largely to an interaction with background activity[4]. The background activity at the recording site was therefore monitored and stimulation was deferred until a period of 80 msec had elapsed with no such activity in excess of 15 μV negative or positive[5]. The minimum interval between stimuli was 3 sec. The hypothalamus was explored millimetre by millimetre. At each recording site the skin of one forepaw was first stimulated, and stimuli were then applied to each pair of uterine electrodes in turn. Whereas cutaneous stimulation evoked potentials in all hypothalamic regions[3] potentials evoked by uterine stimulation were largely limited to two hypothalamic regions. Fig. 1 compares the potentials evoked by cutaneous and uterine stimulation at the same recording site. In Fig. 2 the distribution of responses to uterine stimulation from 13 experiments is plotted on to three diagrammatic sections of the hypothalamus. It can be seen that the responses are virtually confined to the pre-optic and tuberal regions. The distribution of evoked potentials in any one experiment is more restricted than the composite diagram suggests. In two experiments the electrode passed through the supra-optic nucleus. The results of one of these experiments are shown in Fig. 3 in which evoked potentials resulting from uterine stimulation were confined to the supra-optic nucleus and the region immediately surrounding it. The reason that the area from which evoked potentials are recorded appears larger in the composite diagram than in a single experiment may be attributed to variation in the location and size of the supra-optic nucleus from animal to animal, and the possibility that additional nuclei are activated.

Potentials evoked in the hypothalamus by uterine stimulation appeared less regularly than those elicited by cutaneous stimulation, and with a longer latency. Responses evoked by uterine stimulation had a latency of 30–50 msec, whereas responses to cutaneous stimulation had a latency of 15–17·5 msec. In some experiments responses were obtained from stimulation of the electrodes high in the uterine horn, but not from those in the fused portion of the uterus; in others the opposite was true. In all experiments responses were most consistent when using stimulating pulses of long duration, that is, 3 msec. In a single experiment the cerebral cortex in the region of the sigmoid gyrus was explored with a platinum ball recording electrode, and uterine stimulation was found readily to evoke potentials in the somato-sensory region. Presumably such potentials arise from the activation of receptors or their nerve fibres in the myometrium[2].

Our experiments thus demonstrate that neural pathways exist from the uterus to the hypothalamus and apparently also to the cerebral cortex, but doubt must obtain as to the specificity of these relays. Barraclough and Cross[6] found that units in the hypothalamus of the rat responding to pressure on the os cervicis also responded to chilling or pinching the tail. Their recordings were, however, confined to a region of the lateral hypothalamus from which, in the cat, we did not usually observe a response to uterine stimulation. It is also known[7] that many forms of visceral stimulation can evoke potentials in the cerebral cortex.

It is increasingly recognized[8–11] that the onset of labour in the human being is due to an increase in the sensitivity

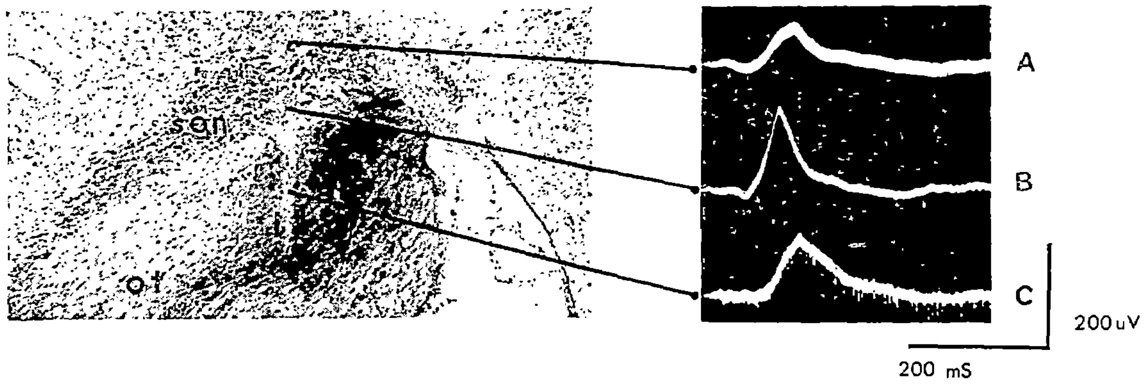

Fig. 3. Localization of potentials evoked by uterine stimulation in the supra-optic nucleus. The photomicrograph shows an electrode track passing through the supra-optic nucleus into the optic tract. The evoked potential illustrated in *A* was recorded just dorsal to the supra-optic nucleus, that in *B* in the ventral portion of the supra-optic nucleus, and that in *C* in the optic tract. *son*, supra-optic nucleus ; *ot*, optic tract

of the myometrium to oxytocin rather than to an increase in the amounts of oxytocin released into the blood. Since the hypothalamus is functionally connected with both neurohypophysis and adenohypophysis it is tempting to speculate that the relay we have demonstrated between uterus and hypothalamus may be concerned not only with the release of oxytocin but also with effecting increased myometrial sensitivity to it, factors which together underly the mechanism of normal parturition.

PHARMACOLOGY

Isolation and Identification of the 20β-Hydroxy Derivatives of 6β-Hydroxycortisol and 6β-Hydroxycortisone in Liquor Amnii

The presence of C-6 oxygenated steroids in neonatal urine was first reported by Ulstrom *et al.*[1]. It has been demonstrated[2,3] that placental tissue incubated under standard conditions, is able to oxygenate at the C-6 position, while the work of Frantz *et al.*[4] has indicated that during pregnancy the urinary concentrations of the polar steroid 6β-hydroxycortisol is elevated above the normal non-pregnant state. It appeared likely, therefore, that similar polar steroids might be present in liquor amnii.

In a previous communication[5], the isolation and identification of 6β,11β,17α,21-tetrahydroxy-pregn-4-ene-3-20-dione (6β-hydroxycortisol) in liquor amnii were reported. At this time the presence of three additional polar steroids was recognized. Two of these compounds have now been identified as 6β,17α,20β,21-tetrahydroxy-pregn-4-ene-3,11-dione (compound 3) and 6β,11β,17α,20β,21-pentahydroxy-pregn-4-ene-3-one (compound 4).

Liquor amnii, obtained at the time of labour, was extracted with ethyl acetate, using the methods previously described[5]. The purified extract was chromatographed in a modified *BuC* system[6] and the chromatogram treated with a 2 : 1 solution of 10 per cent aqueous sodium hydroxide in 50 per cent methanol and 0·02 per cent blue tetrazolium. It was dried in an oven at 60° C for 10 min. When the chromatogram was viewed under ultra-violet light, using a minus blue 4 gelatine filter (Ilford), three brilliant fluorescent zones were observed. The least polar of these has been previously identified as 6β-hydroxycortisol (compound 1) (ref. 5). Quantities of the other two zones (compounds 3 and 4) were collected from subsequent chromatograms, and were carried through a series of chemical and enzymatic steps. Identification of these 20β-hydroxy derivatives of 6β-hydroxycortisol and 6β-hydroxycortisone was based on the properties as listed in Table 1. The products from each procedure were compared chromatographically with reference steroids. In each case an agreement of R_F values was found.

Table 1. Properties of the 20β-Hydroxy Derivatives of 6β-Hydroxycortisol and 6β-Hydroxycortisone

	Compound 20β-6β-OHF		Compound 20β-6β-OHE	
	Isolated	Ref.	Isolated	Ref.
1 Ultra-violet absorption in ethanol	238 mμ	238 mμ	238 mμ	238 mμ
2 Reaction with blue tetrazolium	Neg.	Neg.	Neg.	Neg.
3 Mobility in chromatographic system Mod. *BuC* (ref. 6)	0·01	0·01	0·03	0·03
4 Mobility after the oxidation of the product from Reaction 3 with sodium bismuthate				
B/50 syst. (ref. 9)	0·24	0·24	0·32	0·32
*LB*21/80 (ref. 9)	0·01	0·01	0·03	0·03
5 Mobility after acetylation of the product from Reaction 4 *LT*/2185 (ref. 9)	0·15	0·15	0·31	0·31
6 Mobility after further oxidation of the product from Reaction 5 using chromic acid *LT*/2185 (ref. 9)	0·31	0·31	0·31	0·31
7 Mobility after reduction of the product from Reaction 4 using *Zn*/*HAc* (ref. 9) *LT*/2185 (ref. 9)	0·24	0·24	0·38	0·38

The configuration of the side-chain was elucidated using the enzyme 20β-hydroxysteroid dehydrogenase[7], and by an examination of the chromatographic properties of the steroids. The reference steroids for this comparison were obtained by treating 6β-hydroxycortisol and 6β-hydroxycortisone with sodium borohydride at 0° C (ref. 8).

This work was carried out during the tenure of a research grant to one of us (M. L.) from the Medical Research Council of Ireland.

20β,6β-hydroxycortisol was kindly supplied by Prof. W. Klyne and Dr. C. B. Thornton from the Steroid Reference Collection, Westfield College, London.

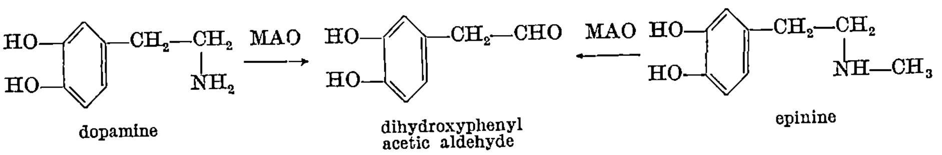
Formation of Tetrahydropapaveroline from Dopamine *in vitro*

In 1938, Holtz *et al.*[1] reported that dopamine, which is pressor in the cat, was converted to a depressor substance after incubation with monoamine oxidase (MAO), for example, extracts of guinea pig kidneys. These authors suggested that the depressor agent might be dihydroxyphenyl acetic aldehyde, the primary deamination product of dopamine, since the addition of semicarbazide prevented the formation of the depressor substance.

To ascertain this assumption, experiments were now performed with epinine, which should also be deaminated by MAO to yield the same aldehyde:



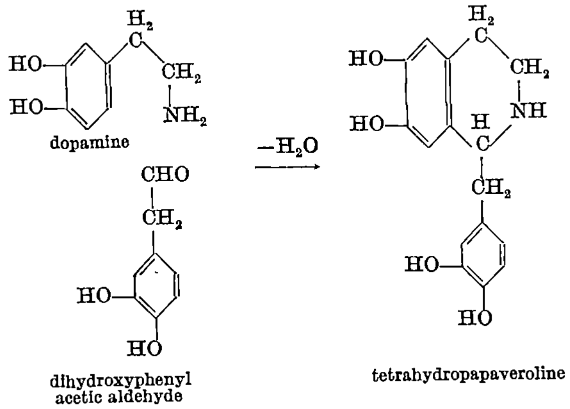
dopamine

dihydroxyphenyl acetic aldehyde

epinine

It was found, however, that epinine was not converted to a depressor agent on incubation with MAO (rat liver mitochondria) but only inactivated[2]. Thus, the blood-pressure-lowering substance formed from dopamine was unlikely to be identical with the dihydroxyphenyl acetic aldehyde.

From previous experiments it was known to us that primary, but not secondary, catecholamines *in vitro* readily condense with aldehydes, for example, pyridoxal 5′-phosphate, to yield Schiff's bases with subsequent formation of tetrahydroisoquinolines[3]. Therefore, we postulated that the dihydroxyphenyl acetic aldehyde formed from dopamine by MAO would similarly react with unchanged dopamine molecules, to form the corresponding tetrahydroisoquinoline derivative: tetrahydropapaveroline (THP), a compound synthesized as early as 1909 by Pyman[4] and reported by Laidlaw[5] to be a blood-pressure-lowering agent:



dopamine

dihydroxyphenyl acetic aldehyde

tetrahydropapaveroline

That THP was indeed formed from dopamine during incubation with MAO is shown in Fig. 1. Incubates deproteinized with perchloric acid were extracted into *n*-butanol at *p*H 4·0, returned to 0·1 N hydrochloric acid and subjected to thin-layer chromatography according to Stahl[6], using *n*-butanol/acetic acid/water (8 : 2 : 2) or *sec.* butanol/formic acid/water (15 : 3 : 2) as solvent systems. This method provided clear separation of dopamine R_F = 0·38 (bottom row) and THP R_F = 0·47 (top row). The chromatograph further demonstrates that in the incubates (*B*, *C* and *D*) THP was formed, and that its amount increased with growing incubation time, 2·5, 5 and 10 min, while that of dopamine decreased. In the incubate *A*, however, the addition of the MAO inhibitor 'Pargyline' (benzyl-benzylmethyl-propynylamine) had prevented the formation of THP.

The deproteinized incubates *A* and *C* were tested on the blood pressure of a cat by intravenous injection. As can be seen from Fig. 2, the incubate *A* with blocked MAO had a pressor effect due to the unchanged dopamine, whereas 5-min incubation of dopamine with the intact enzyme was sufficient to yield a depressor agent, the blood-pressure lowering action of which resembled that of authentic THP (and of isoproterenol) in that it was abandoned after infusion of nethalide (isopropylamino-1-(2-naphthyl)-ethanol hydrochloride), a sympathetic β-receptor blocking agent[7] (Fig. 2*C*). Thus, it was evident that THP and incubate *C*—in contrast with 'musculotropic' papaverine (Fig. 2, *P*)—exerted their depressor actions through the stimulation of sympathetic β-receptors.

It should be pointed out that the—atropine resistant—depressor action of dopamine *per se* in the rabbit[8] was 'papaverine-like', in so far as it remained unaffected by nethalide[2]. Since dopamine in the rabbit was also depressor after the injection of dibenzyline, which abandoned completely the pressor action of noradrenaline[2], it became unlikely that dopamine should lower the rabbit's blood pressure by replacement of vascular noradrenaline, as suggested by Burn and Rand[10].

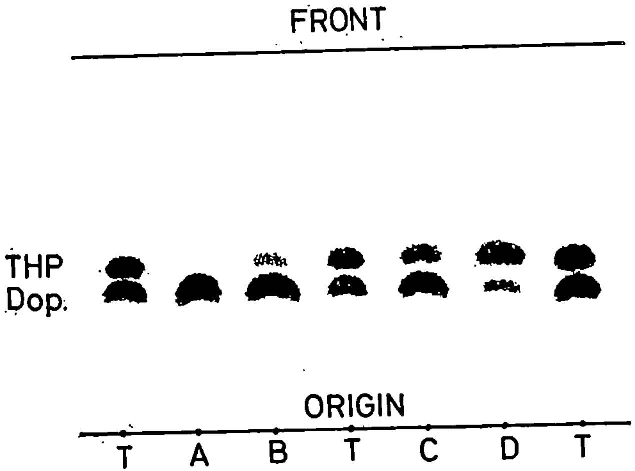


Fig. 1. Formation of tetrahydropapaveroline during incubation of dopamine with monoamine oxidase. Thin-layer chromatography according to the method of Stahl (ref. 6), using silica gel *G* (Merck) suspended in sodium phosphate buffer *p*H 6·8, addition of 1 per cent $NaHSO_3$. Solvent system: *n*-butanol/acetic acid/water (8 : 2 : 2). Spray: Goldenberg's reagent (ref. 9). *T*, mixture of authentic dopamine (Dop) and tetrahydropapaveroline (THP); *A*, *B*, *C*, *D*, incubates of Dop with MAO (rat liver mitochondria). Addition of neutralized ascorbic acid in *A*–*D* to protect the phenolic OH-groups against oxidation, of pargyline in *A* prior to incubation, to inactivate MAO; incubation time 2·5 min (*B*); 5 min (*C*); 10 min (*D* and *A*). 37° C; *p*H 7·4; O_2

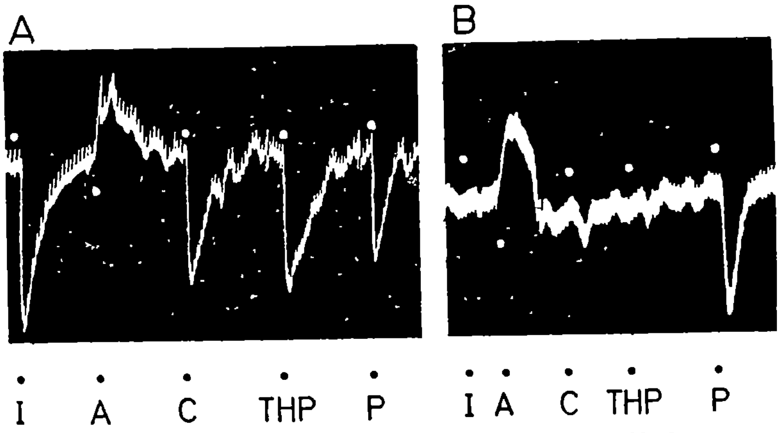

Fig. 2. Action of the incubates *A* and *C* (see Fig. 1) on the cat's blood pressure. Cat (3 kg): chloralose–urethane anæsthesia; intravenous injections of: *I*, 1 μg isoproterenol; *THP*, 10 μg tetrahydropapaveroline; *P*, 1 mg papaverine. *A*, before, *B*, after intravenous infusion of 3 mg/kg nethalide

A paper entitled "Pharmakologie des Tetrahydropapaverolins und seine Entstehung aus Dopamin" will appear in *Arch. exp. Path. Pharmak.*, 248, 387 (1964).

Function of *N*-Acetyl Aspartic Acid in the Brain : Effects of Certain Drugs

N-Acetyl-L-aspartic acid (NAA) was discovered by Tallan *et al.* in 1956 and shown to be unique in its restricted localization to the brain of vertebrate species and in its very high concentration in that organ[1]. Occurring at a level of approximately 1 mg/g of brain, NAA is second only to glutamic acid in the level of free amino-acids in this tissue. Numerous attempts, using a variety of drugs and experimental procedures, to change the concentration of NAA in the brain have met with little success. Thus, electric shock, insulin shock, ammonia intoxication, and the administration to animals of tranquillizers, central nervous system depressants or convulsants, all failed to alter significantly the concentration of NAA in the brain[2-4].

It was reported recently that several drugs, classified as monoamine oxidase (MAO) inhibitors, when administered to rats appeared to produce a rise in the concentration of NAA in the brain[5]. As part of a larger study in this laboratory designed to disclose the function of this unusual amino-acid, it was decided to repeat and extend this observation.

In our investigations, *Ha/ICR* Swiss mice were used. Drugs were administered intraperitoneally as six daily injections, except for hadacidin (*N*-formyl hydroxyamino-acetic acid), which was given as a single dose, and 5-hydroxytryphophan (5HTP) and dihydroxyphenylalanine (DOPA), which were given every 3 h for a total of four injections. The animals were killed by cervical dislocation 4 h after the last injection of drug; the brain tissue was removed and deproteinized. The NAA content of the brain extract was determined essentially by the method of Fleming[6]. This procedure utilizes a kidney deacylase preparation to convert NAA to acetate and aspartate, oxalacetic transaminase to convert aspartate to oxaloacetate, and malic dehydrogenase to convert oxaloacetate to malate. Since the last reaction utilizes NADH, the amount of NAA in the sample can be calculated from the spectrophotometrically determined extent of oxidation of NADH to NAD.

Table 1. Effect of Drugs on the Content of *N*-acetylaspartic Acid (NAA) in the Brain of the Mouse

Drug	Dose (mg/kg)	NAA content of brain μg/g (mean value ± S.D.)	Probability (calculated from *t*-test)
Saline (5)*	—	974 ± 41	—
Iproniazid (9)	100	1,415 ± 245	0·0125
*JB*516 ('Catron') (5)	12	1,120 ± 77	0·025
Tranylcypramine ('Parnate') (10)	15	1,013 ± 82	Not significant
Isoniazid (5)	110	1,339 ± 147	0·005
Imipramine (10)	25	1,165 ± 138	0·005
L-5HTP (10)	50	1,205 ± 79	0·005
L-DOPA (5)	50	980 ± 106	Not significant
Reserpine (10)	0·75	825 ± 114	0·05
LDS-25 (5)	0·25	776 ± 97	0·015
Hadacidin† (5)	100	796 ± 67	0·005

* Number in brackets refers to number of animals.

The following drugs had no effect: pentobarbital, prochlorperazine ('Compazine'), amphetamine, atropine, 4-hydroxybutyric acid, γ-butyrolactone, β-methyl aspartate and NAA.

† The hadacidin was kindly supplied by Dr. H. Shigeura, of Merck, Sharp and Dohme.

The results of these experiments (Table 1) suggest a relationship between NAA and 5-hydroxytryptamine (5HT), since: (*a*) many agents that produce a rise in the level of 5HT in the brain also produce an increased concentration of NAA: (*b*) although some of the agents are monoamine oxidase inhibitors and cause a rise in catecholamines as well as 5HT in the brain, the administration of DOPA, in contrast to 5HTP, had no effect on the level of NAA; (*c*) both LSD-25 (an antagonist to 5HT in peripheral systems) and reserpine (which lowers the brain-level of 5HT) produce a fall in the amount of NAA in the brain. In addition, it should be noted that no correlation exists between brain-levels of NAA and inhibition of monoamine oxidase, since isoniazid caused a rise in the amino-acid concentration but is not an MAO inhibitor, while tranylcypramine ('Parnate') is an inhibitor of MAO and yet does not significantly change the level of NAA in the brain.

The inability of administered NAA to affect the endogenous level of NAA in the brain suggests that the amino-acid cannot pass the blood-brain barrier; this conclusion also is supported by a subsequent experiment in which it was found that the intraperitoneal injection of isotopically labelled NAA did not cause an appearance of labelled NAA in the brain.

Experiments are in progress in an attempt to understand the suggested relationship between 5HT and NAA.

HÆMATOLOGY

Inherited Variants in Serum Ceruloplasmins of the Pig

By means of chromatography and electrophoresis on starch gel, Morell and Scheinberg[1] showed at least four different molecular components of ceruloplasmin in preparations from the plasma of 9,109 human donors. Then McAlister *et al.*[2] presented evidence for multiple ceruloplasmin components in human sera. Using vertical starch-gel electrophoresis to resolve the ceruloplasmins combined with direct chemical and enzymatic analysis on the gel, they defined five distinct proteins having one or more characteristic properties of ceruloplasmin. The enzymatic analysis used by these workers was based on the work by Holmberg and Laurell[3], who showed that ceruloplasmin could oxidize a number of substances, the best substrate being *p*-phenylenediamine (PPD). Using the PPD oxidase activity as a measure of the ceruloplasmin in sera of different species, it was shown by McCosker[4] that pig sera has more than twice the activity of human sera and four times that of other domestic species.

By combining horizontal starch-gel electrophoresis in a discontinuous system and oxidation of PPD, three inherited ceruloplasmin types have been found in sera from one out of three breeds of pig investigated.

The starch-gel technique of Smithies[5], as modified by Poulik[6] using *tris*-citrate buffer adjusted to *p*H 7·6 for the gel, and sodium hydroxide–boric acid buffer for the tanks as modified by Lush[7] was used to separate the serum proteins. Electrophoresis was carried out in a refrigerator at +5° C, and a voltage gradient of 6 V/cm was applied for 30 min, then adjusted to 10–12 V/cm for the remainder of the run until the brown line was 11 cm from the insert line.

The top half of each gel was stained with 1 per cent nigrosin in a methanol–acetic acid–water solution, and the bottom layer stained according to the method described by Morell and Scheinberg[1] with modifications. In their method, paper strips saturated in a solution of 1·0 M sodium acetate buffer (*p*H 5·1) containing 0·5 per cent *p*-phenylenediamine dihydrochloride were pressed on the cut surface of the gel for 1 min, and then removed. The gel was then placed in a closed, moist chamber and allowed to stand for 1–3 h at room temperature until dark purple bands developed.

In the modified technique for pig sera, a similar solution of acetate buffer (*p*H 5) and PPD was used. Instead of using paper strips, however, it was found, like Uriel[8], that total immersion of the cut gel in the buffer at 37° C gave better results. The optimum time for the ceruloplasmin variants to be clearly distinguishable was approximately 45–60 min after incubation. At this stage the gel was photographed and the different types classified. After incubation for 1 h the oxidase activity of the ceruloplasmin on the PPD resulted in a diffuse purple staining reaction, and began to obliterate any bands which were previously discernible.

The three ceruloplasmin types obtained are illustrated in Fig. 1. The schematic drawing shows the interpretation of these types. It is presumed on the basis of segregation studies shown in Table 1 that the homozygotes appear as three bands with the middle band showing the darker staining reaction. The two homozygous types are recognized and classified as types *a* and *b* with type *a* being the faster-migrating protein. A combination of these two types is shown in the heterozygote type *ab*, which has five bands.

Table 1. SEGREGATION OF CERULOPLASMIN TYPES AMONG OFFSPRING OF DIFFERENT MATINGS

Mating type ♂ × ♀	No. of matings	Segregation of offspring *a*	*ab*	*b*	Total
ab × *ab*	1	2	3	0	5
ab × *b*	2		6	1	7
b × *ab*	1		3	3	6
b × *b*	43			223	223

Table 2. FREQUENCY OF Cp-a AND Cp-b ALLELES IN THREE BREEDS OF PIG

Breed	No. of animals tested	Frequency of Cp alleles *a*	*b*
Large white	113	0	1·0
Landrace	83	0·05	0·95
Wessex	28	0	1·0

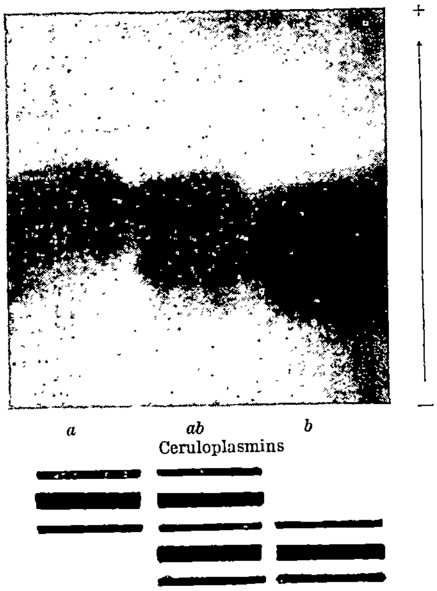

Fig. 1. Starch-gel electrophoresis of pig sera showing the three ceruloplasmin types. A diagrammatic interpretation of these types is also shown

In relation to the other serum proteins of pig blood, the ceruloplasmins are in the same zone as the transferrins at a gel buffer *p*H of 7·6. At this *p*H they appear as three bands in the homozygote form as described above. With a gel buffer *p*H of 8·2, however, they appear as two bands and are in front of the transferrin zone. When staining with benzidine stain[9] for haptoglobins and hæm-binding globulins the oxidizing ability of ceruloplasmins may interfere with the interpretation of the former. At a gel buffer *p*H of 8·2, the ceruloplasmins appear as faint lines between type 3 hæm-binding globulin and the saturated haptoglobin[10].

It is proposed that the three types described above are controlled by two allelic genes at a single locus. The sera from the offspring of 47 different matings of tested parents were examined and the results are shown in Table 1. All mating types were not available, because of the low frequency of type *a* in the parent population. Despite the small numbers for this type, the segregation results appear to be in agreement with the genetic hypothesis of two alleles at a single locus. It is proposed that these alleles be referred to as Cp^a and Cp^b, and the three phenotypes are designated Cp-a, Cp-ab and Cp-b.

The gene frequencies of the Cp^a and Cp^b alleles were calculated from random samples obtained in three pedigree breeds of pigs. These frequencies are shown in Table 2. The type *a* ceruloplasmin was not found in either the Large White or Wessex pigs examined. So far it has only been found in the Landrace breed, and appears to be of relatively low frequency.

This work was carried out during the tenure of a senior research fellowship from the Pig Industry Development Authority. I thank Dr. H. P. Donald, director of the Animal Breeding Research Organization, for facilities, and Dr. J. G. Hall for his advice.

IMMUNOLOGY

Human Pancreas-specific Isoantigens

Pancreas-specific isoantigens have been detected in rabbits[1] and rhesus monkeys[2] following experimental isoimmunization. It has also been reported that isoantibodies and autoantibodies occur in the sera of patients with various types of pancreatic disease[3-5]. Attempts were made in this laboratory to confirm the findings in man using the same techniques of agar-precipitation and indirect hæmagglutination. Difficulty was experienced since normal serum or globulin often gave precipitin lines in agar. Any specific effect from the interaction of serum from patients with pancreatic disease and human pancreas extracts could therefore not be distinguished from non-specific precipitation.

Similar difficulty in the interpretation of agar-precipitation reactions of normal serum or globulin and homologous pancreas extracts has also been reported in pigs[6]. In this instance the serum factor responsible appeared to be a heat stable α-globulin. The substances in porcine pancreas responsible for the reaction were found in all supernates and sediments from differential centrifugation of pancreas homogenates and were inactivated at 56° C for 1 h. Many other workers have reported precipitation reactions in agar which were not due to antigen–antibody systems[7-12]. These usually involved the interaction of normal serum components with various tissue homogenates and in one case a reaction between normal serum and a bovine pancreatic enzyme[12].

Unfortunately, other serological techniques such as complement-fixation and tanned-cell hæmagglutination have given non-reproducible results in the testing of human sera and human pancreas extracts or homogenates. In an attempt to avoid the difficulties of non-specific effects and of non-reproducibility that have plagued the weak reactions of isoimmune sera, the heteroimmunization of rhesus monkeys with individual human pancreas homogenates was considered.

Human pancreas and other organs from individuals of either blood group O or B were obtained at autopsy within 5 h *post mortem* and stored at −50° C until used. Extracts (25 per cent w/v) in isotonic saline were made by homogenization in a high-speed blade-type homogenizer (Servall Omnimixer). The homogenates were then centrifuged at 60,000*g* and the supernates used for testing. The whole homogenate was used as the immunizing antigen.

Young rhesus monkeys 5–10 lb. were injected intradermally and subcutaneously with 1·5 ml. pancreas extract incorporated in 'Difco' Freund complete adjuvant. The animals were trial bled after 2 weeks, and if antibody titres were satisfactory the animals were completely bled. Other monkeys were given a booster immunization with adjuvants and killed 10–14 days later.

The complement-fixation test proved to be the serological test of choice since agar precipitation reactions were also noted with normal monkey serum and human pancreas extract. Antigen titrations were performed by mixing serial dilutions of human pancreas extracts with 1 : 10 diluted monkey serum inactivated at 65° C for 10 min and 1 : 18 diluted guinea pig complement (Hyland Laboratories). Inactivation at 65° C rather than 56° C was used to differentiate immune reactions from the natural complement-fixing antibodies of the Kidd–Friedewald type[13]. The test was incubated overnight at 4° C and then sheep cells sensitized with 2·5 hæmolytic units of amboceptor were added. Antigen titres were expressed as the reciprocal of the highest dilution of antigen giving complete fixation of complement with the 1 : 10 diluted antiserum. Antiserum titres were expressed as the reciprocal of the highest dilution of antiserum giving complete fixation of complement with serial dilutions of antigen.

The sera from monkeys immunized with individual human pancreas homogenates were tested by complement-fixation with an extract of their respective immunizing antigen. Most of the animals immunized had antiserum titres of 20–80 after the primary immunization or after one booster immunization. Antigen titres were usually 40–160. The antisera which reacted with the individual pancreas extract used for their production were then tested with other organ extracts from the same individual in order to establish their serological specificity. Some of the monkeys produced antibodies which reacted with extracts of other tissues from the same individual. These sera were not investigated further. Many of the monkeys produced antibodies that reacted only with pancreas and not with other human tissues such as kidney, liver, spleen, lung, heart, salivary gland, submaxillary gland, parotid gland, gastric mucosa, and intestinal tract mucosa. Absorption with human A, B or O erythrocytes did not inhibit the complement-fixation reaction with pancreas extract. Normal monkey serum and pre-immunization bleedings of the immunized animals, inactivated at 65° C for 10 min, did not react with any of the human tissue extracts tested.

The antisera did not react with any rhesus monkey pancreas extract but some did react with the single extract of chimpanzee pancreas tested. Extracts of other primate pancreases were not tested.

Those immune sera which contained pancreas-specific antibodies were then tested with various individual pancreas extracts by the complement-fixation technique. The reactions of six antisera with ten pancreas extracts are shown in Table 1. The antisera reacted with the particular pancreas extract used for immunization and with some, but not all, of the other individual pancreas extracts. Several different reaction patterns were observed as depicted in Table 1.

10	+	0	0	0	0	0	0

+, *C.F.* antigen titre >20.

0, *C.F.* antigen titre <10.

Antigen titres were expressed as reciprocal of highest dilution of pancreas extract giving complete fixation of complement with 1 : 10 antiserum.

It was not possible to determine the number of antigenic systems by absorption with individual extracts and re-testing. Sera absorbed with pancreas extracts in a concentration necessary for complete inhibition of antibody activity became strongly anticomplementary. This anticomplementary effect could not be overcome by high-speed centrifugation or addition of enzyme inhibitors to the extracts.

Since the rabbit and monkey pancreas isoantigens had been shown to be present in pancreatic secretions[2], human pancreatic secretions were also examined. Specimens aspirated from duodenal tubes before and after patient stimulation with secretin were tested by complement-fixation for the presence of pancreas isoantigens (Table 2). Antigens which reacted with some, but not all, of the monkey antisera were present in the secretions. Specimens from different individuals reacted with various antisera in a manner similar to individual pancreas extracts. There was no predictable increase or decrease in antigen

titre at various time intervals after stimulation with secretin. Samples taken after stimulation with pancreozymin have not been available for testing.

The nature of the pancreas-specific isoantigens in man, rabbits and monkeys has not been established. A possible function of the antigens could be enzymatic since they are located in the secretory portion of the acinar cells[2] and are present in the secretions of these cells. However, direct demonstration of enzymatic activity of the pancreas isoantigen–antibody complexes or inhibition of enzyme activity by antibody has not as yet been successful. Much further work must be performed before these isoantigens can be associated with pancreatic disease.

Effect of Hydrocortisone Hemi-succinate on Immune Lysis of Sheep Erythrocytes

The effect of hydrocortisone on immune lysis was examined by titrating guinea pig complement in the presence of various concentrations of the steroid. Sheep erythrocytes, sensitized with rabbit anti-sheep cell hæmolysin, were used as the indicator system for complement activity; a 50 per cent lysis end point was used. Complement activity was not detectable in the presence of 5 mg/ml. hydrocortisone; the titre was reduced significantly by concentrations as low as 0·01 mg/ml.

In order to attempt to determine the mechanism of this antilytic action the following experiments were carried out.

Pre-treatment of complement with hydrocortisone for periods of up to 30 min did not result in any greater reduction in titre than was observed with the same concentration of steroid added at the same time as the sensitized cells. This suggests that the steroid does not have a direct action on free uncombined complement.

Dialysis against isotonic saline of a mixture of sheep red cells, lysin, complement and sufficient hydrocortisone to inhibit lysis was carried out. After dialysis for 2 h complete lysis of the erythrocytes had occurred, indicating that the combination of hydrocortisone with the reactants was unstable, the hydrocortisone passing through the dialysis sac and allowing normal lysis to occur.

A similar unlysed mixture of cells, lysin, complement and hydrocortisone was incubated for 1 h, and the cells were then washed three times in saline. They failed to lyse on further incubation, but could be lysed by the addition of complement, indicating that antibody but not complement was attached to the cells. It is presumed that the complement remained free, and was removed along with the hydrocortisone by the washing procedure. This suggestion was confirmed by the use of the conglutination reaction. Sheep erythrocytes were incubated with either guinea pig or horse complement, both with and without hydrocortisone, and with heated normal bovine serum as a source of conglutinin and naturally occurring anti-sheep cell antibody. Conglutination occurred in the tube containing horse complement but no hydrocortisone; lysis took place as expected in the guinea pig complement control tube. Neither lysis nor conglutination occurred in the two tubes containing hydrocortisone. This experiment and the preceding data would suggest that hydrocortisone hemi-succinate obstructs immune lysis of sensitized erythrocytes by preventing the attachment of one or more complement components. In preliminary experiments hydrocortisone has been found to inhibit the lysis of erythrocytes by hypotonic salt solutions. This observation suggests that the steroid modifies the red cell surface. The modification of cell surface suggested may account for the failure of complement-binding. At the same time the effect of this and other steroids is being investigated using various other lytic systems.

BIOLOGY

DNA, PNA and Protein Contents in a Rapidly Differentiating System, the Rat Tapeworm (*Hymenolepis diminuta*)

The role of the nucleic acids, deoxypentosenucleic acid (DNA) and pentosenucleic acid (PNA), in the growth and differentiation of organisms has been thoroughly examined and characterized. Rapidly growing tissues usually display rapid synthesis of DNA, PNA and protein. The synthetic rate of these constituents in a given tissue may be estimated by the relative amount of each present. Most of the systems that have been investigated in this regard have required the use of several different individual preparations at different stages of development. Tapeworms, such as *Hymenolepis diminuta*, should be ideal organisms for the examination of certain principles of growth and differentiation, for along the length of the strobila is a gradient of developmental stages, all within the same individual. The experiments reported in this communication were designed to test the usefulness of the tapeworm in a typical examination of growth and development.

The rat tapeworm was maintained in male rats of the Sprague–Dawley strain[1]. Adult worms were flushed from the host's small intestine with Krebs–Ringer solution[2], *p*H 7·4, with 0·05 M 2-amino-2-hydroxymethylpropane-1,3-diol (*tris*) acid maleate[3]. The tapeworms were divided along their length into 3 equal sections, representing the anterior, middle and posterior thirds of the worms. The three portions of worms obtained did not correspond exactly to the immature, mature and pregravid–gravid regions as described by Fairbairn *et al.*[4], but resulted in some overlapping of these regions. Each group was pooled separately and, along with similar batches of whole worms, treated immediately. We used a modification of the procedure outlined by Schneider[5] for the extraction of the nucleic acids. The diphenylamine reaction for deoxypentose[6] and the orcinol reaction for pentose[6], coupled with the Fiske–SubbaRow phosphate determination[7], were used to obtain the amounts of DNA–P and PNA–P present in the tapeworm tissue. Protein was estimated using the method of Lowry *et al.*[8].

The results of this investigation are summarized in Table 1. The values shown represent the average values of at least two separate determinations. Values expressed in Table 1 for DNA–P, PNA–P and protein based on the fresh weight of the tissue corresponded as well to those based on both nitrogen content of the tissue and unit of tissue (for example, μg DNA–P/whole worm). The anterior portion of the worm is known to be a region of rapid growth by cell division, while various stages of differentiation of the tissues and organs occur in the middle and posterior thirds[9]. There is also a metabolic gradient[10], in which the anterior region is the most active. The metabolic activity steadily decreases toward the posterior of the worms.

Table 1. DNA–P, PNA–P and Protein Contents in *Hymenolepis diminuta*

Region of tapeworm	μg of DNA–P/ g tissue	μg of PNA–P/ g tissue	mg of protein/ g tissue	μg of DNA–P/ mg protein	μg of PNA–P/ mg protein	PNA : DNA/ mg protein
Whole worms	36·3	155·3	98·5	0·37	1·58	4·27
Anterior 3rd	52·0	197·5	120·5	0·43	1·64	3·81
Middle 3rd	27·0	149·0	98·0	0·28	1·52	5·43
Posterior 3rd	20·5	137·0	79·0	0·26	1·73	6·65

It was not surprising, then, to find a similar gradient of DNA, PNA and protein in *Hymenolepis diminuta*. The ratios of PNA–P to DNA–P in the different regions of the tapeworms, where the ratio was lower in the more rapidly growing anterior region, and increased in the regions where differentiation of the tissues and organs occurs, agreed with the general pattern found for other growing systems. In addition, our results complement those of Cheng and Jacknick[11], who examined DNA and PNA in the different regions of *Hymenolepis diminuta* using histochemical techniques. The latter authors localized regions with greater concentrations of DNA and PNA at the cellular and tissue level.

We made several unsuccessful attempts to isolate and characterize the DNA from *Hymenolepis* using several different methods[12–14], and modifications thereof. Whether our lack of success was due to the inapplicability of these methods to cestode tissue (simultaneous extraction of mouse liver gave a good preparation of DNA), or due to the tapeworm having a low molecular weight DNA[15], was not established. The diphenylamine-positive material that was obtained by one of these methods[14] possessed no demonstrable thymine derivative.

Campbell[16] has shown that *Hymenolepis diminuta* degrades uracil and thymine to β-alanine and β-aminoisobutyric acid, respectively, by the reductive pathway. Investigations on the regeneration of mammalian liver tissue[17–19] have suggested that the reductive pathway for pyrimidine degradation is involved in the regulation of growth by effectively increasing the pyrimidine pool available for nucleic acid synthesis. *Hymenolepis diminuta*, or similar tapeworms[20], would appear to be an excellent source of material for the further investigation of this problem.

This work was supported in part by a grant from the National Science Foundation (13406). We thank Mrs. Evelyn Hake and Mr. William Kitzman for their assistance in infecting the rats with the cysticercoids.

A Cold Precipitable Protein in the Lens

The biochemical basis for the phenomenon termed 'cold cataract' (that is, opacification of lenses due to cooling) has been elucidated. A soluble protein which comprises approximately 10 per cent of the total soluble lens protein and which precipitates both in lenses and in aqueous extracts of lenses when they are cooled below 10° C has been isolated. This finding validates the suggestion made by van Heyningen[1] that a protein is responsible for clouding of mammalian lenses in the cold. It has been further observed that cold precipitation is a reversible process, since warming the lenses or extracts results in complete restoration of their transparency.

Fig. 1 is a series of photographs of lenses removed from normal seven-week-old Holtzman white rats and cooled by placing them on a watch-glass supported in a beaker of crushed ice. The first photograph (*a*) was taken about 10 sec after the watch-glass was illuminated; the second (*b*) after 20 sec, and the third (*c*) after 30 sec. The change from total opacity to total transparency obviously accompanies the increase in temperature from 4° C up to about 25° C.

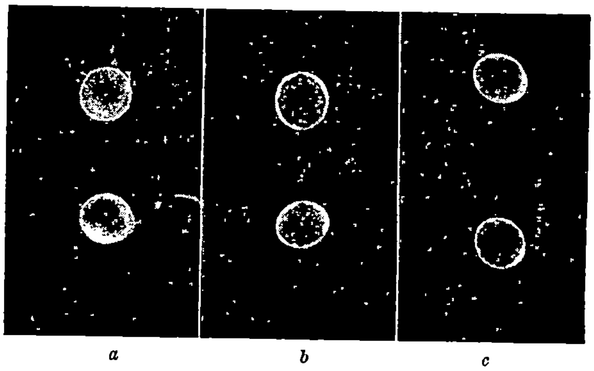

Fig. 1. Solubilization of CPP in cooled rat lenses due to warming (*a*) for 10 sec, (*b*) for 20 sec, (*c*) for 30 sec

Crude preparations of the cold precipitable protein (CPP) are isolated merely by homogenizing lenses in several volumes of distilled water, sedimenting the insoluble matter at 20° C at 20,000 r.p.m. for 1 h and then sedimenting the CPP at 0° C (at which temperature it is insoluble) at 20,000 r.p.m. for 1 h. The cold supernatant contains the total soluble protein minus the CPP. In order to purify the CPP repeated cold recrystallizations are carried out. Fig. 2 is a series of photographs of a test-tube containing an aqueous solution of recrystallized CPP at 12 mg/ml. which was cooled in a beaker of crushed ice. The first photograph (*a*) was taken about 20 sec after removal of the tube from the ice; the second (*b*) after warming the tube by hand for 20 sec; the third (*c*) after warming for about 1 min. Again, the loss of precipitability accompanied the increase in temperature.

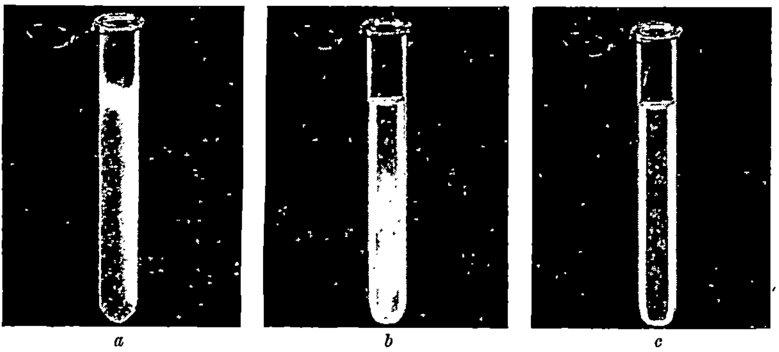

Fig. 2. Solubilization of CPP in a water extract of rat lenses due to hand warming (*a*) for 20 sec, (*b*) for 40 sec, (*c*) for 1 min

The protein nature of this recrystallized, dialysed, cold-precipitated material has been established by ultraviolet absorption, immuno-diffusion, electrophoretic and ultracentrifugal investigations. This work shows further that the CPP contains representative species of each of the three major classes of lens protein. CPP also contains approximately 1–1·5 per cent soluble RNA.

Physico-chemical investigations now in progress indicate that the property of cold precipitability is dependent on the concentration of CPP in solution; a concentration of 3 mg/ml. or more is required for precipitation. Loss of cold precipitability in the lenses of rats 8 weeks of age or older may be due to an increase in lens fluid volume or a decrease in the amount of CPP of a soluble form.

Cold precipitation is also dependent on *p*H; CPP does not precipitate when solution *p*H values are 4·0 or lower.

The solubility or lack of solubility of the protein species making up the CPP appears to depend strongly on the balance between hydrogen bonding and hydrophobic bonding as described by Sheraga[2]. At low temperatures, breakage of some hydrophobic bonds and an increase in hydrogen bonding may lead to precipitation of the CPP sub-units, while at slightly higher temperatures (that is, 20° C or higher) some inhibition of hydrogen bonding accompanied by favourable conditions for hydrophobic bonding may result in dissolution. The dependence of precipitability on *p*H may also be due to changes in hydrophobic and hydrogen bonding.

Deep Water Corals as Fish Food

DIRECT observations reveal fish to be predators on most species of reef corals. Biting of the tip ends of branches, rasping the surface layers of the polyp, and rasping of the algae or other organisms attached to the non-living surface of the coral, are among the many methods used in obtaining the polyp of the coral and associated animals and plants as food. Direct correlations can be obtained between the occurrence of certain kinds of fish and the type of coral—a relationship which may be largely attributed to the sheltering effect of the coral. Hiatt and Strasburg[1], however, found a direct relationship between the coral and fish occurrences in terms of both habitat and predation.

Demonstration of predation by fish on corals from deeper waters cannot be accomplished so easily, for direct observations cannot be made. The evidence of predation must, perforce, rest on examination of stomach contents of fish, or indirectly on evidence of damage sustained by the coral which is most probably attributed to the biting of fish. To my knowledge there has been no published account of the presence of coral in the gut of fish from deep water. Difficulties are expected in the recognition of coral fragments in fish, for few corals can be taken in their entirety, and the coralla of many forms will be too light and fragile to stand up under the mastication and digestive processes. Mr. Gordon Williams of Auckland, New Zealand, for many years made collections of the stomach contents of fish, and the occurrence of corals in some of these was recently brought to my attention by Dr. A. W. B. Powell, Auckland Institute and Museum. From stomachs of the tarakihi (*Dactylopagrus macropterus*), taken over a period of several years from off Mayor Island, Bay of Plenty, in depths of 35–90 fathoms, Mr. Williams obtained more than 160 species of molluscs (A. W. B. Powell, personal communication) and two species of corals. Although the number of fish stomachs which were examined in order to obtain this collection is not recorded, the relative numbers of the two species of corals are significant. Ninety-eight specimens were recovered, all of which showed some signs of corrosion and some of breakage, although remnants of tissue were present in the internal depths of the coralla of some specimens. Both the species *Kionotrochus suteri* and *Sphenotrochus ralphae* are turbinollid corals which are free living forms, small (up to 1 cm in largest dimension), and have a skeleton which is completely internal to the polyp. Of the 98 specimens of coral, 14 were of *K. suteri* and the remaining 84 of *S. ralphae*. The significance of these proportions is that *K. suteri* is perhaps the most abundant coral in the Bay of Plenty region, being found in great numbers of individuals in a very high percentage of benthonic trawls. *Sphenotrochus ralphae*, on the other hand, although known from a moderately large number of localities, apparently never occurs in abundance. The stomach-content specimens are twice the known number of the species taken alive. Alternative explanations for the disparity are that the tarakihi were feeding in an ecological facies, not yet sampled, in which *S. ralphae* is abundant, or that the larger size of *S. ralphae* makes a more appealing item in the diet of the fish.

Other evidence for the predation of deep-water corals by fish rests with the secondary evidence of the regeneration of coralla severely damaged and broken during life. It is, of course, possible that organisms other than fish may be responsible for some of the observed damage; but the extent and nature of many injuries suggest a large animal, such as a fish. Regeneration of the coral has important implications both in investigations of the growth of coral and in their systematics, for the structures resulting from regeneration may differ significantly in their appearance from those of normal development. Increased recognition of the extent of predation of coral by fish will be of considerable value in both ecological and biological investigations.

Hypomyces Stage of *Fusarium solani* f. *pisi*

ASCIGEROUS stages have not been established heretofore for either of the *Fusarium* pathogens of pea, *Pisum sativum* L., that is, for *F. oxysporum* f. *pisi* (Linf.) Snyd. and Hans., the cause of a vascular wilt, or *F. solani* f. *pisi* (Jones) Snyd. and Hans., the cause of a cortical foot and root disease. Evidence is presented in this communication that the ascigerous stage of the latter pathogen has been discovered and belongs to the genus *Hypomyces*. Although perfect stages are now known for several formæ in *F. solani*, none has yet been established for any member of the species *F. oxysporum*.

In 1959 one of us (T. M.) reported in Japan[1] the isolation of two formæ of *Fusarium solani* (Mart.) App. and Wr. emend. Snyd. and Hans. from mulberry trees. One of them, called *F. solani* f. *radicola* race 2, was shown later to be pathogenic to pea. This fungus, when properly mated, produced red perithecia in culture and was very similar to *Hypomyces* (*Fusarium*) *solani* f. *cucurbitae* Snyd. and Hans. in appearance and sexual behaviour[2,3], since it was heterothallic, had mating (compatibility) types (+), (−), and through mutation developed heterothallism in respect to sex. Hermaphroditic, male and female clones of the fungus also were found. Random crosses of the Japan fungus attempted with other clones of *Fusarium solani* showed that it would cross successfully with a California isolate of *F. solani* f. *pisi*, obtained from the Berkeley laboratory. Later it was discovered there that the California isolate would cross also with two additional Japan isolates of *F. solani* f. *pisi*[3].

About the same time (1962–63) in the laboratory at Berkeley, the original California isolate sent to Matuo was crossed successfully with a number of clones from a collection of isolates of *F. solani* f. *pisi* obtained from various parts of the United States and from England. All these were typical, tested, highly virulent clones of the pathogen, isolated from pea plants infected with root rot in the field.

All isolates were maintained by single spore culture in PDA tubes at room temperature in diffuse daylight, or in daylight supplemented by 12 h of fluorescent light. Crosses were made 20–30 days after single sporing, by pouring a suspension of conidia in sterile water from one clone into tubes containing another. The time required to obtained fertile perithecia varied from 1–6 months. Single ascospores were isolated from these perithecia, and also single ascospores were recovered from individual asci by the method described by El-Ani[4]. Ascospore progenies were analysed for the inheritance of pathogenicity and mating type.

Pathogenicity tests were made by inoculating emerging pea seedlings of the varieties 'Alaska', 'Little Marvel' and 'Davis Perfection' growing in steamed *U.C.* soil mix, with spore suspensions from PDA slants. The seedlings were not injured during inoculation. Two pots each containing 5–7 plants were used in testing each isolate and the tests were repeated 1–3 times. Controls were uninoculated plants, and plants inoculated with *F. solani* f. *phaseoli* (Burk.) Snyd. and Hans., all of which remained free from disease. Tests were terminated after 4–6 weeks. Plants were removed from the soil, washed, and graded as to the degree of virulence of fungus attack. This varied from severe, with killing of seedlings during the first 3 weeks after inoculation, to a trace or almost no disease, 6 weeks after inoculation.

Some of the crosses resulted in fertile perithecia. Asci were removed from these and the ascospores of several individual asci were recovered and tested separately for mating type and pathogenicity. The perithecia showed a 1 : 1 segregation for mating type when back-crossed to their parents or other tester clones.

Inheritance of virulence was investigated in two ways. (1) Ascospore progeny from the aforementioned asci were tested individually. Evidence was obtained that differences in virulence existed between ascospore pairs within each ascus analysed. (2) Ascospores expelled from perithecia resulting from a cross between two clones were tested at random for pathogenicity. They ranged from very virulent to essentially non-virulent. The colonial characteristics of the progeny showed a wider variation than that of the two parents, some clonal colonies revealing little resemblance to either. The variation between sizes of conidia of different ascospore clones was as great as previously described by Snyder and Hansen[5] for the species *F. solani*. Perithecium and ascospore sizes fell into the range of those given in the same paper for the perfect stage, *Hypomyces solani* (Rke. and Berth.) Snyd. and Hans. The variability obtained from these matings of *F. solani* f. *pisi* was similar to that described for *F. solani* f. *cucurbitae* and showed a pattern usual for a heterothallic fungus.

Crosses of various clones of *F. solani* f. *pisi* show beyond question now that this foot and root rot pathogen of pea has a perfect *Hypomyces* stage, although it has never been reported in the field on its host. It is heterothallic, segregates into two mating types, and while very similar in behaviour to that of *H. solani* f. *cucurbitae*, it is not interpathogenic with its host nor inter-fertile with it. However, perithecia form less rapidly on PDA than on other media such as *V*-8 juice agar[6].

Clones of *F. solani* f. *pisi* derived from ascospores varied widely in their virulence on peas as well as in their cultural appearance. Results from the crosses suggest that a recombination of several genes governing virulence can take place, since random ascospore cultures showed a wide range in virulence.

In 1960 W. L. Gordon[7] pointed out that Buxton's[8] report of a perfect stage in *F. oxysporum* was without fact. *Nectria haematococca* (*Hypomyces solani*), a homothallic fungus associated with the latter species, was shown actually to be the perfect stage of a *Fusarium solani*, not of the wilt fungus *Fusarium oxysporum* f. *pisi*. Gordon suggested, however, that Buxton's *Nectria* (*Hypomyces*) might be a perfect stage of *F. solani* f. *pisi*, but did not test its pathogenicity in order to determine this important point.

In the following year one of us[9] published the results of a series of pathogenicity tests, using Buxton's homothallic fungus. They concurred with Gordon as to the identity of Buxton's *Nectria* (Imp. *F. solani*) and showed it to be a saprophyte, biologically unrelated to *F. solani* f. *pisi*. Repeated tests since that time, using isolates obtained directly from the original source, again have shown no pathogenicity under our conditions. The discovery now of a heterothallic perfect stage of *Fusarium solani* f. *pisi* in two different laboratories shows definitely that it, and homothallic *Nectria haematococca* (*H. solani*), are genetically as well as biologically two different and distinct fungi.

Although both compatibility types of *F. solani* f. *pisi* have been found to occur in the United States, its *Hypomyces* stage has been overlooked up to this time, probably because perithecia do not develop readily on PDA, even when the proper mating types are present, and because perithecia apparently do not occur commonly, if at all, on infected plants in the field.

Perfect stages (in *Hypomyces*) now have been produced in pure culture in the Berkeley laboratory not only for saprophytic *F. solani* (which contains both homothallic and heterothallic groups) but also for the tested, pathogenic formæ, *F. solani* f. *cucurbitae*, r1. and r2., *F. solani* f. *batatis* (Harter) Snyd. and Hans., and *F. solani* f. *pisi*. In addition, the Japan laboratory has reported perfect stages in culture for *F. solani* f. *mori* Sakurai and Matuo, *F. solani* f. *xanthoxyli* Sakurai and Matuo, *F. solani* f. *robinae* Matuo and Sakurai, and *F. solani* f. *pisi*. All these reportedly pathogenic formæ are heterothallic in the usual compatibility sense. Also, Zerova[10] has reported *Hypomyces asclepadis* Zerova as the perfect stage of *F. coeruleum* (Lib.) Sacc. (*F. solani* f. *radicicola* (Wr.) Snyd. and Hans.). Perfect stages so far are not known for *F. solani* f. *phaseoli* and *F. solani* f. *eumartii* (Carp.) Snyd. and Hans.

This ascigerous stage of the pea pathogen is designated *Hypomyces solani* f. sp. *pisi* n. c., pathogenic on the underground parts of pea, *Pisum sativum* L., heterothallic, world-wide, with an imperfect stage in *Fusarium solani* f. *pisi* (Jones) Snyd. and Hans.

Nature of Growth-promoting Activity associated with the Culture Filtrates of *Fusarium oxysporum* f. *lycopersici* (Sacc.) Snyd. and Hans.

The growth-promoting activity of the filtrates of the genus *Fusarium* has long been recognized[1-5]. Using a bioassay test for auxins, and distilled water as control, Hirata[2] detected indolyl-3-acetic acid (IAA) in concentrated filtrates, whereas Venkata Ram[3] reported its absence. Their media, in addition to the basal medium (g/l. KH_2PO_4, 1·5; $MgSO_4$, 1; $FeCl_3$, 0·01; glucose, 25 and nitrogen source, either ammonium sulphate at 2·0 g, or asparagine at 1·99 g and water 1 l. (ref. 5)), were used to culture the fungus to determine indole production.

Owing to the structural similarity to IAA, tryptophan was substituted as (*a*) nitrogen source and (*b*) both as a combination of nitrogen and carbon source in all media. Two different strains of *Fusarium oxysporum* f. *lycopersici* were used, the strain from the junior author's laboratory and a virulent strain (*R* 5–6).

Media were used either at *p*H 6·5, or unadjusted. Acidity of all media was critically considered, as tryptophan conversion into indole was known to be inhibited in acid condition, while the conversion was favoured in an alkaline reaction[6].

Erlenmeyer flasks (250 ml.) with 50 ml. of sterile medium were inoculated with 1 cm disk of the actively growing fungus and incubated at room temperature (22°–24° C). The filtrates were analysed at 3-week intervals up to a maximum of 12 weeks. Uninoculated sterile media and sterile distilled water were used as checks.

Two flasks of the same medium were pooled and filtered. The filtrates were shaken three times with equal volumes of peroxide-free ether. Solvents were evaporated *in vacuo* and the residue was dissolved in 2 ml. of glass distilled water or in ethanol and was spotted in Whatman No. 1 paper and developed descendingly, using isopropanol–aqueous ammonia–water (10 : 1 : 1 v/v) (ref. 7). For effective separation of indoles from tryptophan, the papers were developed in a solvent system having methyl ethyl ketone–pyridine–water (75 : 5 : 15 v/v) (ref. 8).

Indoles were detected by various spray reagents. Since Salkowski's reagent has questionable specificity[6,9,10], it was used together with that of Ehrlich and a modified Ehrlich reagent, consisting of 2 g of *p*-dimethyl amino benzaldehyde in 6 N hydrochloric acid (100 ml.) and ethanol (100 ml.). Fresh reagents were used for each determination. After spraying, the chromatograms were dried at room temperature (23°–25° C) and the spots were examined in 24 h.

In addition, both oxalic acid paper and Kovac's tests were performed in all filtrates[11]. All tests were repeated at least 10 times and the results are shown in Table 1.

Table 1. Results of Indole Production by *Fusarium oxysporum* f. *lycopersici* in Cultural Media*

Media	Salkowski	Ehrlich	M. Ehrlich	Oxalic acid test	Kovac's test
(1) Richard's	–	–	–	–	–
(2) Tryptophan Richard's (–nitrogen)	–	–	–	–	–
(3) Tryptophan Richard's (–N and C)	–	–	–	–	–
(4) Basal medium	–	–	–	–	–
Ammonium sulphate	–	–	–	–	–
Asparagine	–	–	–	–	–
(5) Czapek's	–	–	–	–	–
(6) Tryptophan Czapek's (–N)	–	–	–	–	–
(7) Tryptophan Czapek's (–N and C)	–	–	–	–	–
(8) IAA control	+	+	+	–	–
(9) Tryptophan control	–	–	–	–	–

* These results were observed regardless of the strains and solvents employed.

Both strains of *Fusarium oxysporum* f. *lycopersici* produced no indole compounds in the filtrates regardless of media. In one instance, a positive spot for Salkowski's reagent in Richard's medium was observed. However, this could not be repeated.

The fungus grew poorly in tryptophan medium. However, greater utilization of tryptophan was noted when it was substituted as nitrogen and carbon sources as revealed by a faint ninhydrin-positive test. Also this material was utilized only slightly as a source of nitrogen in the presence of a sugar. Tryptophan was apparently utilized in a different biochemical pathway leading to the eventual conversion of nicotinic acid as some of the intermediary products were identified in the chromatograms[12], rather than the conventional pathway of tryptophan conversion into IAA.

Using standard bioassay tests, both Hirata[2] and Venkata Ram[3] suggested that *Fusarium* species produced growth-promoting elements. Hirata[2] also showed a positive colour reaction for IAA, especially in the tryptophan–Czapek's filtrates of *F. solani* and *F. oxysporium* f. *vasinfectum*. No mention of a colour reaction was available using *F. oxysporum* f. *lycopersici* filtrates, although the filtrates exhibited a positive *Avena* coleoptile test. The *p*H of the tryptophan–Czapek's medium used by Hirata was not reported. It was noticed in this laboratory that the *p*H of such medium was 4·6, which was not conducive for tryptophan conversion to indole.

Although Venkata Ram[3] reported a positive bioassay test, he detected no indoles in the culture filtrates. He also reported that the filtrates from Richard's medium with carbon sources as glucose and fructose significantly increased the growth-promoting activity of fungal filtrates and also exhibited a positive bioassay test. It is known that fermentable sugars inhibit the production of indole compounds[7].

Under the conditions of the present investigations it is concluded that no isolatable IAA or other derivatives were produced by *F. oxysporum* f. *lycopersici*. It is suggested that the growth-promoting activities associated with *Fusarium oxysporum* f. *lycopersici* is not of auxinic nature. However, these findings do not preclude the possibility that auxins may be produced by the pathogen *in vivo*.

We thank Dr. K. McDonnell of the Department of Botany, University of Cambridge, for supplying the virulent strain, and Mr. Ray Ito, Department of Political Science, University of Rhode Island, for translating the Japanese text of Hirata's paper.

Influence of the Inoculum and the Medium on the Growth of *Chlorella pyrenoidosa*

I HAVE on more than one occasion considered the practical interest of achieving giant forms of *Chlorella* by treatment with a sugar[1], in order to use them as inoculum in cultures the growth of which it is desired to accelerate. It is known that such giant cells cultivated in a mineral medium devoid of sugar return to their normal form. However, I presumed that the growth of such cultures would be superior to that of cultures inoculated with normal cells. On the other hand, the composition of the culture medium is also an important factor to be considered[4,6].

This communication reveals the decisive influence which the inoculum and the medium, independently, exert on the rate of growth of a culture.

The inoculum is prepared by sowing *Chlorella* cells taken from a mineral medium culture in logarithmic phase of growth, in a medium which induces gigantism with glucose[1]. After four days in this medium, in the dark, at 37° C, the inoculum was centrifuged at 1,000 r.p.m., washed with distilled water, and sown.

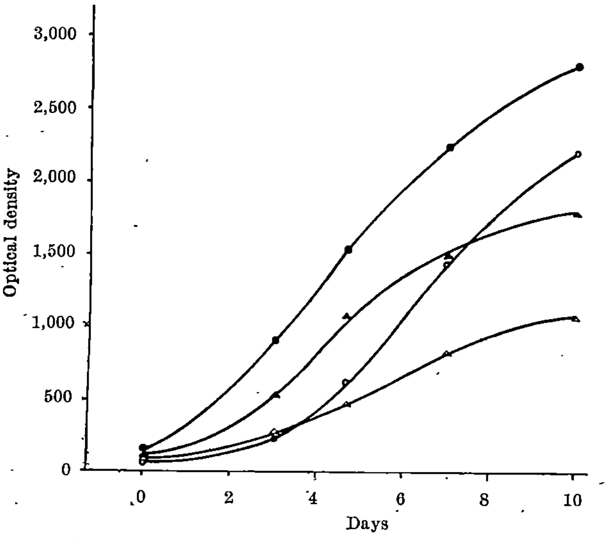

Fig. 1. Growth of *Chlorella* on different media and inocula. Medium *A*: with giant cells (●); with normal cells (○); medium *B*: with giant cells (▲); with normal cells (△)

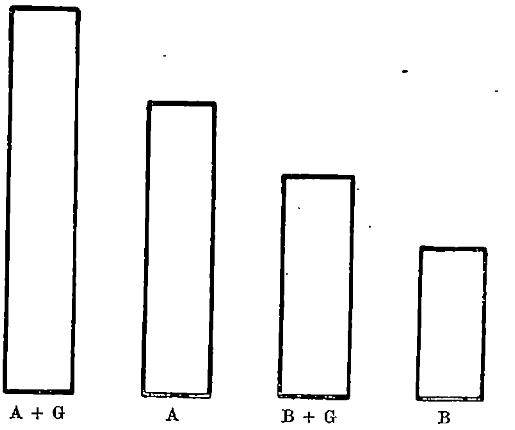

Fig. 2. Relative amount of growth in *Chlorella* cultures of 10-day-old, on different medium, with normal or giant cells (*G*) inoculated

I have examined two mineral media and sown the foregoing inoculum on them with the following compositions and concentrations (g/l.): Medium *A*, KNO_3 1·011; $MgSO_4\cdot 7H_2O$ 0·247; $Na_2HPO_4\cdot H_2O$ 0·621; $NaH_2PO_4\cdot 2H_2O$ 0·089; $CaCl_2\cdot 2H_2O$ 0·015; $FeSO_4\cdot 7H_2O$ 0·007 (in complex form with EDTA); trace elements. Medium *B*. KNO_3 1·250; $MgSO_4\cdot 7H_2O$ 2·500; KH_2PO_4 1·250; $FeSO_4\cdot 7H_2O$ 0·011 (previously dissolved in water acidified with HNO_3); trace elements.

The culture medium is sterilized at 120° C for 20 min. 500-ml. Erlenmeyer flasks were used, in which 200 ml. of medium was placed and sown with approximately equal (in dry weight) inoculations of giant cells. Each experiment was duly checked with an equal dose of normal cells. Six such experiments were made. During the ten days which the experiment lasts the cultures are kept in daylight, at 25° C, and are gassed with a mixture of air and 5 per cent carbon dioxide. The growth of the medium can be measured by optical density using Beckman *DU* with a wave-length of 600 mμ.

Figs. 1 and 2 represent the mean values of the findings in the experiments. The growth is noticeably greater in medium *A* than in medium *B* and within the same medium when giant cells are inoculated. It may be inferred from this that the result of the experiments depends both on the composition of the medium and on the nature of the inoculum. A normal cell culture performed on medium *A* shows, in 10 days, a 100 per cent greater growth than another carried out in the same conditions in medium *B*.

Table 1 gives the quantities of fundamental elements which enter in each medium and their *p*H.

Table 1. PRINCIPAL ELEMENTS IN THE CULTURE MEDIA (g/l.)

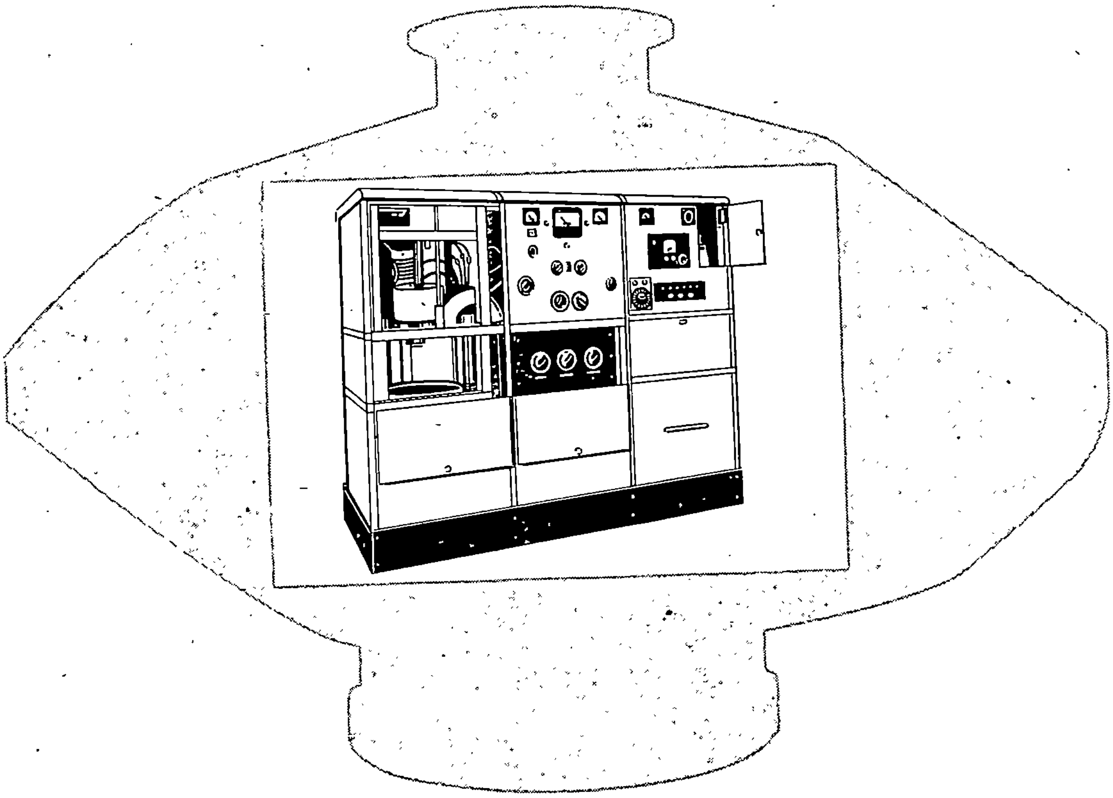
Medium	N	P	S	K	Mg	Fe	Ca	*p*H
A	0·140	0·137	0·032	0·392	0·024	0·001	0·004	6·5
B	0·173	0·284	0·324	0·842	0·246	0·004	—	5·5

Medium *B* strikes me by its greater saline concentration; and if it is considered that the absence of chelating agents in it, which would stabilize the solution of trace elements, the abundance of the precipitate which forms during its sterilization and possibly originates unforeseen, ion imbalances may be explained. On the other hand, medium *A* contains the necessary calcium ion, albeit in minimal quantities, for unicellular green algae and specifically for *Chlorella*[2,3]. The *p*H existing in both media are well within the wide margin of tolerance of *Chlorella*.

The inoculum exerts on the growth an action similar to that of the culture medium in Fig. 2. When inoculating giant cells in medium *B*, 85 per cent more growth was obtained than when inoculating normal cells; whereas in medium *A* the growth is only 41 per cent more.

A BASIC INSTRUMENT

FOR MOLECULAR STUDIES



Beckman®

Model E Analytical Ultra Centrifuge

includes these latest features :

Titanium rotor giving 370,000 'G' and longer rotor life.

Additional rotor giving up to 8 simultaneous U.V. studies.

Monochromator U.V. accessory.

New increased range of cell assemblies.

'Schleiron', 'Rayleigh Interference' and U.V. absorption.

The greatest name in optics

According to Soeder[4], when the division and sporulation processes are delayed or inhibited generally larger cells are originated and these contain an enormous amount of reserve substances. Griffiths[5] has shown that *Chlorella* cultivated in a medium with glucose has its division inhibited and its volume increased, and that its dry weight is considerably greater than when grown in an inorganic medium. These accumulated reserve substances are those which, as I have shown[1], cause a considerable proliferation of autospores in the giant cells, and these, on being carried to inorganic medium and placed in conditions of autotrophism, break the wall of the mother cell and cause in the culture a growth which is notably superior to normal growth.

It is therefore advisable, whenever it is desired to accelerate the growth of a *Chlorella pyrenoidosa* culture and obtain an abundant mass of this in a short time, to use medium *A* inoculated with giant cells.

MICROBIOLOGY

Toxic Action of Hæmolytic *Escherichia coli* isolated from Pigs

Certain hæmolytic strains of *E. coli* are associated with œdema disease and gastro-enteritis of young pigs. Timoney reproduced œdema disease in pigs by injecting supernatant material of the centrifuged intestinal contents from pigs which had died of this disease[8]. Since then, Erskine *et al.*, Sojka *et al.* and Sweeney *et al.* have successfully reproduced the disease by injecting bacterial extracts prepared from hæmolytic strains of *E. coli*[2,4,6]. These reports suggest that œdema disease is caused by absorption of a toxic substance produced by specific strains of hæmolytic *E. coli*.

In contrast to the 'toxæmia hypothesis', Lemcke *et al.* observed severe anaphylactic reaction following injections of polyvalent *E. coli* antiserum into pigs that had shown symptoms of œdema disease and concluded that œdema disease was produced due to an antigen–antibody reaction and therefore this disease is a specific anaphylaxis[3]. Further evidence in favour of this 'anaphylactic hypothesis' on œdema disease and gastro-enteritis complex was presented by Buxton and Thomlinson from their observations on passive cutaneous anaphylactic tests in guinea pigs and by Thomlinson and Buxton from reversed anaphylactic experiments in pigs[1,7].

The work recorded here was carried out to test the validity of each of these two hypotheses and to seek a possible reconciliation. Bacterial extracts of a hæmolytic strain of *E. coli*-0141: *K*85*a,c* (*B*), and a non-hæmolytic strain —*Mac* 429 isolated from a pig were prepared by the method of Erskine *et al.* with minor modifications in that the cells were washed twice in 0·85 per cent sodium chloride solution, and disintegrated by sonic oscillation for 30 min[2]. Total protein content was determined by measuring the amount of precipitate produced with trichloroacetic acid[5].

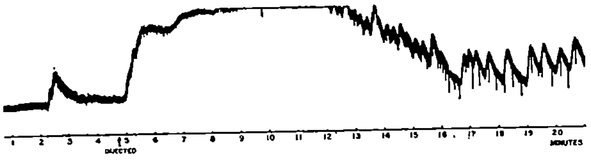

FIG. 1

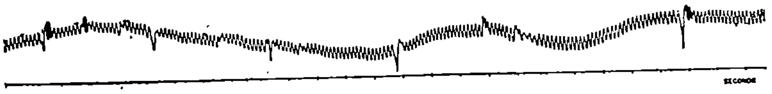

FIG. 2

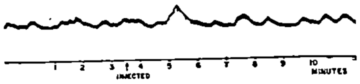

FIG. 3

Fig. 1. Effect of an intravenous injection of 0·5 ml. extract of hæmolytic *E. coli*-0141: *K*85*a,c* (*B*). Speed of the paper 20 mm/min

Fig. 2. Difficulty in expirations, deep and prolonged inspirations accompanied by convulsions are recorded on this graph by running the paper at 20 mm/sec

Fig. 3. Effect of an intravenous injection of 0·6 ml. extract of non-hæmolytic *E. coli*. Speed of the paper 20 mm/min

Each extract was tested on a separate young, healthy, non-sensitized, female guinea pig weighing about 300 g. After anæsthetizing the animal with ether inhalation, its uterus was exposed and the severed right horn was attached to a transducer of an electronic polygraph recorder. About 0·5 ml. of the bacterial extract adjusted to contain 7·0 mg of protein per ml. was inoculated into one of the mesenteric veins.

The reaction of the animal to an injection of hæmolytic *E. coli* extract was observed within 15 sec by a sharp contraction of the uterus and respiratory distress (Fig. 1), the uterus remained contracted for at least 11 min, the rate of respiration increased and the duration of inspirations and expirations became shorter. After this 11-min period of violent reaction, the animal showed signs of respiratory failure with intermittent gasping inspirations and convulsions (Fig. 2) and died within ½ h of the injection.

A lag of 1·5 min followed an injection of the non-hæmolytic *E. coli* extract when the uterus contracted also coincident with respiratory distress (Fig. 3). However, in contrast to the action of the hæmolytic *E. coli*, the reaction lasted for only 1 min and the animal recovered.

The results of these experiments indicate that hæmolytic *E. coli* produce a potent toxin that has a marked effect on non-sensitized guinea pigs. Extracts of non-hæmolytic *E. coli* have a less toxic effect, but whether this difference in potency is due to a different type of toxin produced by the two strains or different amounts of the same toxin is not known. All these data support the 'toxæmia hypothesis'.

We thank Mrs. N. Chopra for protein estimation of the bacterial extracts and Mr. T. W. Chen for his help to run the polygraph.

ENTOMOLOGY

Diuretic Function of the Labial Glands in Adult Giant Silk Moths, *Hyalophora cecropia*

During experiments on the water balance of pupal and mature *Hyalophora cecropia* (Schneider), it was observed that the facial area of the adult may become moist when the hæmolymph is diluted. A similar, but spontaneous, discharge occurs when the adult is emerging, the watery exudate serving to soften the stiff matted silk of the emergence tunnel by which they escape from the cocoon. The fluid is released from labial glands which open through a medial pore situated on the labium between the rudimentary galeæ. These glands, which secrete silk in the larva, survive metamorphosis to the non-feeding adult as a pair of tubes composed of a thick-walled posterior part lying ventrally in the prothorax and a thin-walled, much folded anterior part which unites with its counterpart and opens at the labial pore. The present experiments show that these glands not only persist, but also continue to secrete in the adult, where they become organs of diuresis. This work records the relationship of secretion to physical restraint, and the high rates of secretion caused by dilution of the hæmolymph.

Experiments were first performed on animals the wings and legs of which had been restrained with cellulose tape to facilitate the collection of samples. The secretion of the labial gland was collected in a calibrated capillary tube with a fine drawn tip fixed over the labial pore. The level of fluid in the tube was marked at intervals and the rate of secretion determined by weighing. In young adults restraint with cellulose tape induced a spontaneous production of fluid within 5–10 min, which reached a rate of about 1 μl./min, 15–20 min later. Thereafter the rate of secretion diminished and finally ceased after about 100 min. The mean rate during the entire period was about 0·5 μl./min.

The rate, volume, and duration of secretion varied greatly and appeared to be related to the water content of the animal at emergence : some unconstrained adults, 1 and 2 days old, secreted copiously after injection with distilled water, while others produced fluid only after constraint and injection. It has not yet proved possible to collect labial gland secretion quantitatively from unconstrained animals.

When water was injected into the abdomen of animals which failed to secrete spontaneously after constraint, or into animals that had completed spontaneous secretion, the glands renewed their secretory activity. Fluid appeared within 5–15 min following an injection of 0·25 ml. distilled water, reached a maximal rate for most animals of about 2 μl./min within 20–30 min and continued at a decreasing rate for 1–2 h, giving an average rate of 0·1–0·2 μl./min. Day-old animals injected with 0·17 M sodium chloride secreted at a rate more than double that of distilled water animals (Fig. 1*A* and *B*). One animal (*A*) which received 0·25 ml. 0·17 M sodium chloride delivered 0·276 ml. at a mean rate of 3·6 μl./min.

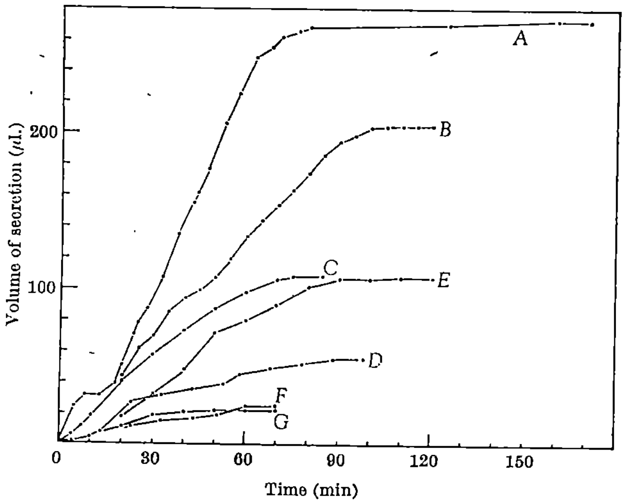

Fig. 1. Volume of labial gland secretion released at labial pore after injection as follows: *A*, 0·25 ml. 0·17 M sodium chloride; *B*, 0·20 ml. 0·17 M. sodium chloride; *C–G*, one animal injected on successive days with 0·25 ml. water

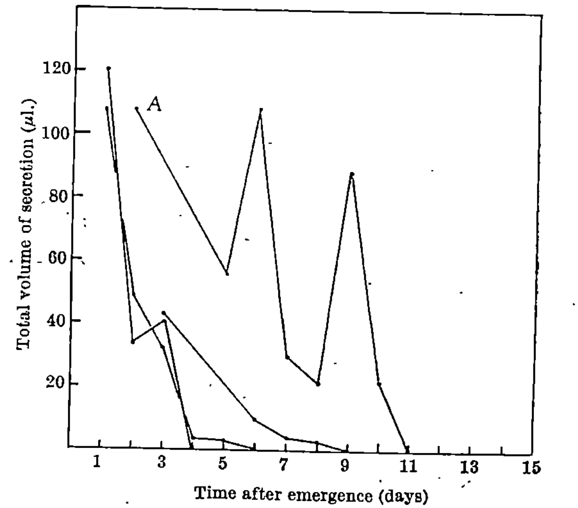

Fig. 2. Change with increasing age in response of labial glands to injections of 0·25 ml. water. Four animals. Animal *A*, which showed a fluctuating change, died on day 15, the others on day 11 or 12

The ability of the labial glands to secrete in response to injection declines during the first few days of the 10–12 day life-span of the adult, but occasional animals have continued to secrete in response to repeated injection of 0·25 ml. of distilled water for as long as ten days (Fig. 2).

Wounding and internal hydrostatic pressure do not appear to be the stimuli for secretion, which could not be induced by injecting peanut oil, though an animal so treated would secrete on receiving an injection of distilled water. Nor does resumption of secretion appear to bear any simple relationship to the osmolarity of the blood, for injections of 1 M glycerol induced secretion as did normal insect saline (0·17 M sodium chloride), and 0·17 M potassium chloride.

Restraint to the legs acting as a stimulus to secretion is probably related to the restraint imposed by the pupal cocoon during emergence for unconstrained animals which failed to respond to injections of water, did so when the legs were restrained, and ceased within seconds when again released. The results so far obtained suggest a reflex mechanism, the threshold for which rises with increasing age. The expenditure of fluid during emergence may influence the extent of subsequent 'spontaneous' discharge.

The striking capacity of the labial glands to respond rapidly to a change in the water content of the hæmocœle suggested the possibility that the labial glands might also play a part in water regulation in the adult. Adult *cecropia*, like many non-feeding adult Lepidoptera, are 'dry' animals : they have a low blood volume, doubtless in the interest of aerodynamic efficiency, and the possibility that the labial glands play a regulatory part in water balance is not yet discounted. A parallel may be found in other labial glands, for example the accessory glands of the heteropteran salivary complex (Edwards, J. S., unpublished results), and possibly the labial glands of the *Thysanura* (Watson, J. A. L., personal comm.). However, the malpighian tubules remain active throughout adult life, as shown by their continued capacity to sequester indigo carmine and to produce urine in response to water load.

Autogeny and Oviposition in Arctic Mosquitoes

Two species of mosquito, *Aedes* (*Ochlerotatus*) *impiger* (Walk.) and *A.* (*O.*) *nigripes* (Zett.), occur at Lake Hazen, northern Ellesmere Island[1]. This arctic site (71° 18′ W., 81° 49′ N.), where the Canada Department of Agriculture has conducted entomological studies in 1962 and 1963, lies within 100 miles of Alert, the most northerly locality at which mosquitoes are known to exist in Canada[2]. Two findings concerning the mosquitoes at Lake Hazen are described here ; unless otherwise specified all remarks refer to both aforementioned species.

Numerous temporary and permanent pools provide larval habitats in the area. The most widespread flowering plant is *Dryas integrifolia* Vahl. (Rosaceae), which adults of both sexes visit frequently to obtain nectar. During the mosquito flying season (late June–mid-August) about 19 species of bird and 8 species of mammal exist in the area, though at a relatively low density[3].

At emergence, ovaries of female mosquitoes are in stages I–II of Christophers[4] and nullipars usually come to bite in stage II, after having mated. Nulliparous and parous females actively seek vertebrate blood and complete ovarian development (that is, reach stage V) about a week after engorgement. However, nullipars can also complete ovarian development, within about the same time, when maintained from emergence with flowers of *Dryas integrifolia* or with sugar (a 15 per cent solution of sucrose) as their only source of food. Females also oviposited under these conditions, except those *A. nigripes* maintained on sugar. On such blood-free diets, ovarian development was attended by extensive, stepped degeneration of oocytes, and this so greatly reduced fecundity that sometimes only a single egg attained stage V (Table 1). Females maintained solely on demineralized water survived up to 20 days (cf. up to 37 days on *Dryas* and sugar) but their ovaries did not develop beyond stage II, and no oocytes degenerated. Evidently access to nectar or sugar is a prerequisite for the process leading to degeneration of oocytes and translocation of food reserves in this type of autogenous ovarian development.

In another experiment, females (mixed nullipars and pars) attracted in Nature were allowed to penetrate the skin of the human bait (thus unequivocally manifesting their intention to bite) and then treated in one of two ways : (1) allowed to engorge ; or (2) removed within 5 sec of having penetrated, presumably before ingestion of blood could have begun. Both groups were then maintained on *Dryas* and sugar. Ovarian development was then completed in all females (31 *A. impiger* and 9 *A. nigripes*) in group (1), and in 8/25 and 1/14, respectively, in group (2). It therefore appears that in some females (at least) autogeny is facultative. However, until the precise stimulus associated with blood feeding which initiates ovarian development is known, this conclusion must remain provisional.

Autogeny in arctic or subarctic populations of mosquitoes has hitherto been discerned in *Aedes* (*O.*) *communis* (DeGeer) in Canada (although only in populations believed not to take blood[5,6]), and in *A.* (*O.*) *flavescens* (Muller) and *A.* (*O.*) *punctor* (Kirby) in Sweden[7]. The present findings establish the existence of autogeny in blood-sucking mosquitoes in arctic North America ; they show that nectar or sugar is required for its manifestation, as in some but not all other autogenous mosquitoes[8], and that the autogeny is associated with decreased fecundity. They strongly suggest, but do not demonstrate, that autogeny is facultative in individual females. In retrospect, it seems likely that Barlow[9] encountered a similar phenomenon in *Aedes* (*O.*) *hexodontus* Dyar at Churchill, Manitoba, although his use of wild-caught females prevented his reaching certainty on this point.

Table 1. SIZES OF EGG-BATCHES IN MOSQUITOES WHICH COMPLETED OVARIAN DEVELOPMENT

Treatment	Species *Aedes impiger*	 *Aedes nigripes*
(*A*) Emerged in captivity:		
Dryas and/or sugar	1–4 (12)*	1–16 (8)
Dryas and sugar; then blood	8–23 (20)	12–41 (4)
(*B*) Caught biting in Nature:		
denied blood; *Dryas* and sugar	2–21 (8)	7 (1)
allowed to engorge on blood	12–76 (30)	20–47 (10)

* No. of mosquitoes in brackets.

The pattern of autogeny recognized at Lake Hazen may have special adaptive significance for mosquitoes in the arctic and subarctic, where potential vertebrate hosts fluctuate widely in numbers[10]. It provides for reproductive continuity during years when vertebrates are scarce or absent, and for a proportionate, large increase in years when they are plentiful. Thus a rich, temporary supply of protein in one year can be used to increase the number of adult females in the next, when, if blood becomes scarce, their greater abundance can to some extent compensate for their reduced fecundity. Accordingly, populations of such mosquitoes probably show numerical fluctuations broadly resembling those of their principal vertebrate hosts; the mosquitoes, however, unlike the vertebrates, will be ensured (by autogeny) against declining beyond a certain minimum density.

The second finding to be reported here concerns the oviposition of *Aedes nigripes*. At Lake Hazen the Sun remains continuously above the horizon (elevation about 6–32°)[11] throughout the mosquito flying season. Despite this, oviposition is periodic. Females of *A. nigripes* oviposit in clearly visible sites (the characteristics of which will be described elsewhere) frequently rendered conspicuous by the corpses of individuals that die there. Females were often seen ovipositing, but only on surfaces with an aspect currently at right angles (in a horizontal plane) to the rays of the Sun. Laid eggs and dead females *in situ* were found only in sites directly insolated between 0600 and 2100 h suntime (solar noon being 1200 h) ; and the overwhelming majority of eggs and females were at sites directly insolated between 1100 and 1300 h. It may be concluded that oviposition is virtually restricted to the period 0600–2100 h and that it achieves its greatest rate near solar noon. The environmental cues which maintain such periodicity merit study. If, as seems probable, the temperature of the site plays a critical part, the duration of daily oviposition may be expected to decrease as the Sun's maximum daily elevation becomes progressively less during July and August. A consequence of this periodicity is that oviposition sites have a southern to south-westerly aspect and thus are usually among the first parts of the pond margin to become free of snow in June when the overwintered eggs hatch.

VIROLOGY

Bats and Arboviruses in East Africa

The natural cycles of the majority of the arboviruses are unknown. Even with yellow fever virus—which belongs to Casals's Group *B*—where extensive investigations have shown the natural cycle to involve forest dwelling primates and mosquitoes, many workers think that there still remains at least one other as yet undiscovered cycle of virus maintenance.

In Africa, bats which are abundant and attractive to mosquitoes[1] have as yet been surprisingly little investigated in relation to yellow fever and other arboviruses. Investigations at this Institute during 1951 with the fruit bat *Eidolon helvum* (Kerr) showed that 1/40 serum samples from bats collected in Kampala contained neutralizing antibodies to yellow fever virus, and circulation experiments with this virus detected in one instance a low level of viræmia[2]. We understand that recent work in the United States supports this finding.

In West Africa, Lagos bat virus was isolated from the brain of a fruit bat, *Eidolon helvum* (Kerr)[3], and recently two virus strains belonging to Casals's Group *A* and numerous strains belonging to Casals's Group *B* have been isolated from bats of the genus *Scotophilus* in Senegal[4–6].

In East Africa a Group *B* virus, Entebbe bat salivary gland virus, was isolated from *Tadarida* (*Chaerephon*) *limbata* (Peters) in 1957 (ref. 7). A continuation of this work on bats, which will be reported fully elsewhere, has during the past year led to a number of findings:

(1) Seven strains of two other Group *B* viruses and two further strains as yet unidentified have been isolated from the salivary glands of 479 bats belonging to the genus *Tadarida*.

(2) Hæmagglutination inhibitory antibodies to Group *B* virus antigens have been found in 91 out of 98 (93 per cent) acetone-extracted sera collected from *Tadarida* spp.

(3) Hæmagglutination inhibiting antibodies to chikungunya virus have been found in the serum of one bat and hæmagglutination inhibiting antibodies to Bunyamwera virus have been found in that of another.

(4) In the laboratory it has been shown that two species of the genus *Tadarida* will circulate Bunyamwera virus in titres greater than 3·0 log LD_{50} for at least 6 days. Yellow fever circulation experiments have so far been unsuccessful.

(5) Zika virus circulated in low titres in a bat of the genus *Rousettus*.

The findings suggest that there is an exceptional relationship between bats and Group *B* viruses, for we cannot find records of other apparently healthy vertebrates from which such a high rate of arbovirus isolation can be made and which at the same time show such a high percentage of antibodies. The view that the relationship between Group *B* viruses and bats is not an exceptional local occurrence is supported by the finding of antibodies neutralizing dengue virus in the sera of bats of the genus *Pteropus* in Australia[8] and antibodies neutralizing Tick-borne encephalitis virus in Europe[9]. Furthermore, in America the Group *B* Rio Bravo virus was isolated from bats in Texas[10] and a Group *B* virus has been isolated from bats in Montana[11]. That Group *B* viruses may be found circulating in the blood of bats and thus be available to infect hæmatophagous arthropods is shown by laboratory investigations with Japanese *B*, St. Louis and tick-borne encephalitis viruses[12–14].

The viræmia investigations with Bunyamwera virus indicate that bats may circulate arboviruses of another group. In this respect it appears of great interest that Downs *et al.* have recently reported the isolation from bats of a number of strains of Tacaribe virus, which complement fixation shows to be related to Argentinian hæmorrhagic fever (Junin) virus[15].

It is apparent, therefore, that bats are potentially of great importance in the wild-cycle of arboviruses and warrant further investigation on a wide international basis.

Recovery of the Viral Antigen in a Cell by means of Double Radioactive Labelling

The use of isotopes has rendered possible the examination of virus development at the cellular level[1,2].

We have investigated the reproduction of the fowl plague virus (FPV) using the method of autoradiography. A double labelling with radioactive isotopes was used for the differentiation of the synthesis of viral RNA and proteins (antigens).

The strain Waybridge of FPV and dermo-muscular cells of human embryos were used. Trypsinized tissue cultures, 2×10^6 cells/ml. suspended in Medium 199 with 10 per cent of bovine serum, were placed on cover slips, 2 cm × 2 cm, and incubated at 37° C for 6 days, and then infected with FPV, 100 ID_{50} per cell. A rat serum with the hæmagglutination-inhibition titre 1 : 1,280 was labelled with iodine-131 according to the techniques of Francis *et al.*[3] and Liebster *et al.*[4], having used sodium salt of iodine, specific activity 6 μc./ml. γ-globulins were obtained by the rivanol method; their specific activity was 0·05 μc./ml.

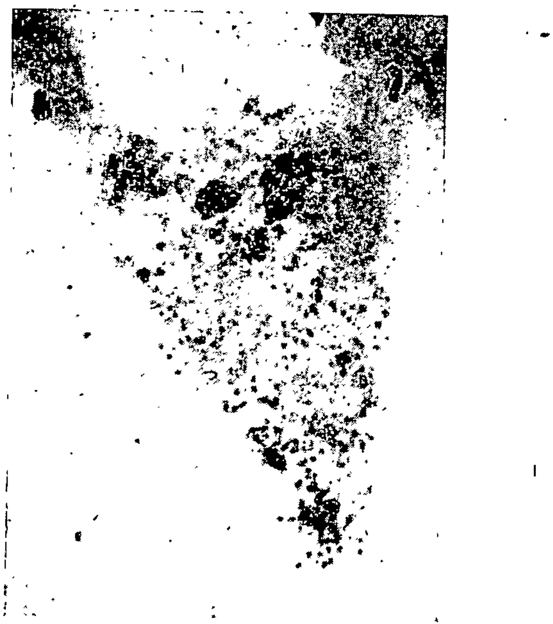

Fig. 1. Autoradiograph of the cell, infected with fowl plague virus

The preparations of the dermo-muscular tissue of human embryos were treated with the virus within 20 min at 4° C; residual virus was removed by triple washing in the cold Hanks's solution; then Medium 199 with 10 per cent serum and ^{14}C-adenine, 0·01 μc./ml., were added and preparations were incubated at 37° C. After exposure for 3 h, cells were washed with Hanks's solution, fixed in Carnoy's solution, covered with γ-globulin labelled with iodine-131, exposed for 20 min and then washed again. Then they were covered with film, type *MR*, and exposed with silica gel in the dark at 4° C for 7 days. Developed preparations were stained with methylene blue.

Fig. 1 demonstrates some results of the method of the double radioactive labelling. ^{14}C-adenine as nucleic acid precursor is presented as small points randomly scattered while γ-globulin labelled with iodine-131, blocking viral antigen, forms large autographs and conglomerates. So far as carbon-14 and iodine-131 have different energies of decay, it is possible to observe simultaneously the reproduction of viral nucleic acid and protein as autographs of different size in the same cell.

Effect of Actinomycin *D* on Measles Virus Growth and Interferon Production

Actinomycin *D* combines *in vitro* with DNA in mammalian cells and results in impairment of DNA synthesis and of DNA-dependent RNA synthesis[1,2]. This results in uncoupling DNA from cellular protein synthesis.

Certain animal riboviruses (polio, mengo and Newcastle disease viruses (NDV)) have been shown to replicate in actinomycin *D* treated cultures, indicating their independence of cellular nucleic acid function[2,5].

Interferon production in cell cultures occurs in response to treatment of cells with foreign nucleic acids[6]. Because actinomycin *D* inhibits cellular RNA synthesis and hence protein synthesis, it would be expected to inhibit production of interferon.

Bukrinskaya and Zhdanov[7] demonstrated a decrease in the latent period of Sendai virus production in actinomycin *D* treated chick fibroblasts. They attempted to explain their results by suggesting that actinomycin *D* may have inhibited messenger-RNA of the cell, resulting in early direction of cellular enzymatic systems to virus production.

Treatment of chick fibroblasts with actinomycin *D* prior to inoculation with Chikungunya virus resulted in inhibition of interferon production accompanied by enhancement of viral growth[8,9]. Actinomycin *D* has also been shown to cause enhancement of growth of Semliki forest virus (SFV) and NDV (ref. 10).

This communication reports preliminary investigation of the effects of actinomycin *D* on production of interferon and virus titres in measles-infected chick fibroblast cultures.

*H.Ep.*2 cells infected with the 'Edmonston' strain of measles virus were disrupted by three cycles of freeze-thawing. This fluid, which after centrifugation and membrane filtration contained $10^{3 \cdot 7}$ plaque producing doses/ml., was used as inoculum for chick embryo fibroblast monolayers maintained at 37° in medium 199 with 5 per cent fœtal calf serum. After 8 days the whole cultures were disrupted as described and assayed for measles virus by plaque production in *H.Ep.*2 cell monolayers and, after high-speed centrifugation (120,000*g*), for interferon. The end-point of interferon titration was expressed as the reciprocal of the dilution causing 50 per cent inhibition of plaque formation by Sindbis virus in chick fibroblast monolayers.

Both yield of infectious virus and interferon production were compared from normal cultures and from cultures of cells pretreated with actinomycin *D* at a concentration of 0·01 μg/cm^2 of monolayer (0·1 μg/ml.) for 4 h.

Normal cultures yielded fewer than 10 infectious particles/ml. with an interferon titre of 12 while actinomycin-treated cells yielded $10^{2 \cdot 7}$ infectious particles with undetectable interferon production. These results support the view that actinomycin allows increased virus yield by inhibiting interferon production. Thus monolayers of a cell type normally showing a high degree of 'resistance' to measles virus and to which this virus must normally be 'adapted' by repeated passage are rendered more susceptible by suppression of interferon production.

Further experiments are now being carried out to characterize this interferon and examine production of measles interferon in other cell systems.

Lipid in a Purified Preparation of Tomato Spotted Wilt Virus

Electron micrographs of tomato spotted wilt virus (TSWV), when stained by uranyl acetate or lead hydroxide, revealed the presence of an envelope surrounding an aggregate of several heavily staining spheroidal particles[1]. The envelopes stain only lightly with these reagents, suggesting that the envelopes contained lipid. Accordingly, a purified preparation of the virus was examined to test this hypothesis. By direct extraction with organic solvents the preparation was shown to contain about 20 per cent extractable lipid. Thin-layer chromatography of these extracts revealed a number of spots which gave a blue colour when treated with a molybdenum-based stain[2]. Although lipid has long been known to form part of some animal viruses there is no record of the presence of a lipid in a plant virus.

The virus was a sample of strain *E* of TSWV. The virus was extracted from systemically infected leaves of *Nicotiana glutinosa* by homogenizing them in the buffer solution at *p*H 7, removing non-viral material by alternate cycles of low- and high-speed centrifugation followed by two cycles of sucrose density-gradient centrifugation as described by Best and Palk[1]. The virus was identified in the light-scattering band of the density-gradient tubes by its infectivity and characteristic size and shape under the electron microscope[1]. After removing the sucrose and buffer salts the virus was freeze-dried and then stored over phosphorus pentoxide.

The dry virus was extracted for lipid by the micro-extraction method described by Thomas[3], using the apparatus described by Schaffer *et al.*[4]. Total lipid was determined by extracting 1- to 2-mg portions of the virus preparation in micro centrifuge tubes three times with 100-µl. portions of 1 : 1 chloroform–ethyl ether and two washings with 100-µl. lots of the methanol + ether solvent. The combined extracts and washings from each tube were evaporated under nitrogen to extract all the lipid. This was then extracted ten times with 50-µl. portions of petroleum ether. The solid extracted by petroleum–ether will be called lipid fraction *A*. The residue was also weighed and called lipid fraction *B*. Blanks were run on lipid-free samples of pure tobacco mosaic virus.

The efficiency of the method was tested by extracting known amounts of pure stearic acid. The percentage recovery in four trials using 200-µg samples was 96, 98, 100 and 95 respectively.

Table 1. LIPID CONTENT OF STRAIN *E* OF TOMATO SPOTTED WILT VIRUS

Wt. of virus (µg)	% lipid *A**	% lipid *B**	Total lipid (%)
1,019	8·6	10·3	18·9
1,008	9·1	10·6	19·7
1,066	9·2	n.d.	—
1,495	8·2	9·6	17·8
Mean value	8·8 ± 0·46	10·2 ± 0·55	

* *A*, petroleum-ether-extract. *B*, residue from methanol, chloroform, ether-extract after extraction with petroleum ether.

As shown in Table 1, the total extractable lipid amounted to about 19 per cent of the preparation, and was about equally divided between the petroleum-ether-extract and the residue from the methanol, chloroform, ether-extract.

Although the concentration of virus in the infected leaves is not high it was of interest to compare the lipid content of healthy and virus-infected leaves. Accordingly, on each of five occasions ten *N. glutinosa* plants were selected at random from a uniform batch. Five plants were inoculated with TSWV and the other five were kept as controls. About 3 days after they had developed symptoms the systemically invaded leaves were gathered. The corresponding leaves of the healthy control plants were gathered at the same time. Both lots of leaves were then homogenized and the lipid was extracted from aliquots and assayed by the method of Kates *et al.*[5]. The results in Table 2 show that the infected leaves contain a significantly higher percentage of lipid than the healthy controls. On a fresh-leaf basis the difference is 40 per cent, and on a dry-weight basis of leaves the difference is 10 per cent (the infected leaves having a higher dry-weight content than healthy ones).

Table 2. LIPID CONTENT OF HEALTHY LEAVES OF *Nicotiana glutinosa* AND OF LEAVES INFECTED WITH STRAIN *E* OF TOMATO SPOTTED WILT VIRUS

In all five experiments 5 g of leaves (fresh wt.) were extracted

Expt. No.	Dry wt. as % of fresh wt.		mg lipid per g fresh wt.		mg lipid per g dry wt.	
	Healthy	Infected	Healthy	Infected	Healthy	Infected
1	—	—	8·1	14·2	—	—
2	7·5	8·9	8·1	10·6	108	119
3	7·5	8·8	8·2	11·4	109	118
4	9·0	10·8	9·2	12·8	103	119
5	8·0	8·7	8·5	10·1	107,	116
Mean			8·42	11·82	106·75	118·0
S.E.M.			0·21	0·76	1·315	0·707
Level of significance (probability based on '*t*' test)			1%		0·1%	

It is clear that the differences between healthy and virus-infected leaves is highly significant. The question which now arises is the extent to which the lipid we find in our preparations of TSWV is virus-specific. The electron micrographs of the purified preparations[1] strongly suggest that the lipid is located in the envelopes (as distinct from membranes) which encase several of the 50-mµ particles. The electron micrographs of sections through virus-containing lesions on inoculated leaves suggest that the virus may 'bud-off' from membranous structures of the host-cell cytoplasm[1]. It is, therefore, possible that the envelopes are derived from host material during the 'budding-off' process. In other experiments, the lipid extracted from TSWV preparations was compared qualitatively with extracts of material prepared from control leaves. A preparation was made from these healthy leaves, using differential- and density-gradient centrifugation as for the preparation of virus. A sample was withdrawn from the gradient tubes at the same depth as that from which the virus band was withdrawn. The material was freeze-dried, extracted with organic solvents in the way already described for the virus, and the extracts were run with the extracts from the virus on the same thin-layer chromatograms prepared according to Müldner *et al.*[6]. Using the molybdenum-containing stain of Wagner *et al.* several blue spots were obtained. Some of these were common to both virus and control extracts, but one spot was present only in the extract from the virus. The nature and significance of this are being investigated.

In view of the fact that this virus is transmitted in Nature by an insect in which it has an incubation period[7], it is not so surprising to find that it contains lipid.

Multiplication of Rauscher Virus in Cultures of Mouse Kidney Cells

RAUSCHER virus induces a characteristic malignant hæmopathy when inoculated into adult or new-born mice of various strains, mainly that of *BALB/c* (ref. 1). In order to handle a system which would give a good production of virus *in vitro*, we cultured cells taken from various organs of animals inoculated with Rauscher virus several days previously. Among the organs tested, we obtained valuable results with cultures of young mice kidneys. The kidney always being spared during the course of Rauscher leukæmia, this production of virus is worth while mentioning.

New-born *BALB/c* mice were inoculated intraperitoneally with 0·1 ml. of an extract prepared according to Moloney's method[2] from spleens of *BALB/c* mice carrying Rauscher leukæmia in the erythroblastic stage. The titre of the inoculated extract varied from 10^4 to 10^6 ID_{50} per 0·1 ml. Animals were killed 6–10 days later. Kidneys were cut up with scissors, washed three times in Hanks's fluid, trypsinized for 2 h in a 0·5 per cent trypsin solution, *p*H 8·0, at 37° C, without stirring, and a strong manual agitation gave a cell suspension which was collected in a medium made of casein hydrolysate containing 15 per cent calf serum. Cultivation was performed in Kahn tubes with an initial inoculum of 5 × 10^5 cells per ml. of nutrient medium, which was changed twice a week. After 5–7 days at 37° C, a continuous cell monolayer was obtained. The following tests were performed: (1) daily observation of an eventual cytopathic effect; (2) weekly hæmagglutination tests with erythrocytes of *BALB/c* mice and of Wistar rats at 37° C, 4° C and 22° C; (3) weekly hæmadsorption tests on the same red blood cells at 4° C and 37° C; (4) weekly assay for an interfering activity using Sindbis virus (100 TCD_{50}/tube) as challenge; (5) every fortnight, search for an interferon activity with the supernatants, using as a test the action on the growth of Sindbis virus (100 TCD_{50}) in cultures of mouse fibroblasts; (6) at varying times, the supernatants or cell-supernatant mixtures, frozen and thawed three times, were inoculated (0·1 ml. intraperitoneally) into new-born mice and these animals were examined each week, in order to detect a splenomegaly.

The kidneys of healthy animals were cultured and tested, following the same procedure.

Moreover, the *in vitro* inactivation of Rauscher virus was examined by inoculating new-born mice with virus incubated alone in the culture medium at 37° C, or in the presence of cells in which we had obtained no multiplication (*KB*).

With kidney cultures originating from mice inoculated with Rauscher virus, no cytopathic effect has been observed, and the examination of hæmatoxylin–eosin stained cover-slips in Leighton tubes confirmed this finding. No hæmagglutinating or hæmadsorbing activity could be detected. The existence of interferon in the supernatants was never demonstrable and no interfering activity on the growth of Sindbis virus was observed. On the other hand, bioassays proved the permanent presence of Rauscher virus in the cultures.

Table 1 gives the details of one among the six experiments performed.

Table 1. INOCULATION OF NEW-BORN *BALB/c* MICE WITH SUPERNATANTS OF INFECTED KIDNEY CULTURES

Time of sampling after initiation of the culture (days)	No. of injected animals surviving weaning	No. of leukæmias	%	Latency (days)	Average latency (days)
14th	21	18	85	41–181	86
32nd	9	9	100	55–127	106
42nd	10	10	100	54–115	98
57th	10	10	100	90–120	103
71st	5	5	100	72–120	98

In nearly all the animals inoculated with material originating from these cultures and sampled between the 7th and 71st day, an erythroblastic proliferation in the spleen and liver, typical of the first stage of the Rauscher disease, was induced.

However, it may be noticed that intrasplenic hæmorrhages were rare, leading to a diminished early death-rate and allowing the apparition of late generalized leukæmias, the cytological type of which was erythroblastic, myeloid or undifferentiated. Two choroleukæmias have been observed, but no lymphoid leukæmia has appeared.

Myeloid leukæmia is not usually described as part of the Rauscher disease but was very frequent in our experiments[3]. We think that one cannot link this fact to the action of any virus other than the Rauscher virus, because antisera prepared either by Dr. Rauscher or in our laboratory cross-neutralize the virus.

Kidney cultures of non-inoculated *BALB/c* mice, examined in the same manner, never produced virus as revealed by the bioassay. Inoculation of young mice with virus incubated in the presence of *KB* cells or in the culture medium alone at 37° C showed that the virus is completely inactivated within 24 h.

These results demonstrate that Rauscher virus actively multiplies in cultures of mice kidney cells. The presence of a residual virus seems very unlikely because of the considerable dilution realized by the renewals of the culture medium (as many as twenty changes before the final inoculation) and by the previously demonstrated conditions of virus inactivation. The type of the disease induced and the relatively long latency period indicate that the amount of virus in the cultures is fairly small, at least 2 log 10 less than in the plasma of leukæmic mice. It is of interest to note that the *in vitro* inoculation with Rauscher virus of cultures of healthy mouse kidneys (still in progress) seems to give much more irregular results.

Rauscher virus, therefore, multiplies in kidney cells as early as 7 days after the inoculation of the animal and can be cultivated in these cells for prolonged periods, although this non-hæmopoietic organ does not show any pathological alteration during the course of Rauscher leukæmia. This phenomenon shows once again that leukæmia viruses grow in many different types of cells and induce a transformation in only some of them.

GENETICS

Quick Preparation of Corolla Chromosomes from Flower Buds

THE standard practice of obtaining somatic chromosomes from root-tips[1] for counting is often inconvenient, particularly for species in the wild and for perennials in the field. In grafted species, for example, cultivated top-fruit clones, it is impractical to use root-tips and it may be necessary to obtain counts from meioses in pollen mother cells. Several methods are available, however, for examining chromosomes from other meristematic tissues[2] such as young leaves from vegetative tips and stipules, but these do not always prove satisfactory. Burns[3] has recently provided a useful method for making preparations of somatic chromosomes from corollas in *Nicotiana* spp. Her schedule is somewhat lengthy, and the prepared slides are not ready for examination for three days. We have been able to shorten this schedule, and have found the modifications satisfactory with the several genera tested. The abridged technique successfully used for rapidly preparing chromosomes in corolla tissue is given here.

Margins and bases of unexpanded corollas are the most active regions, and buds which are too large must not be taken. Petals from open flowers do not show divisions. Buds 2–3 mm in size are taken in the mornings, and the green corollas are dissected out and placed in a tube containing a few ml. of 8-hydroxyquinoline solution (0·438 g in 1 l. distilled water) to which a drop of saturated maltose is added. This pretreatment should not be allowed to rise above room temperature. The minimum time for pre-treatment is 2 h, but this depends on the material and may be increased to 4 h. The corollas are fixed in modified Carnoy solution (6 parts 95 per cent alcohol : 3 parts chloroform; 1 part glacial acetic acid) which must be freshly prepared for each batch of tissue. A suitable time for satisfactory fixation is 30 min; but the material can be stored in this solution without harm for several weeks at 2° C. Hydrolysis is carried out in a solution made from 2 parts of 1 N hydrochloric acid and 3 parts of the fixative for not more than 5 min at 60° C. Staining is carried out on a slide using lacto-propiono-orcein[4]. Corollas are left on the slide for 2 min with two drops of the stain, heated gently and squashed in the usual manner. Should the chromosomes appear to be clumped together they may be spread by flooding the squash with 45 per cent acetic acid and re-tapping and squashing. If the material is over-stained, de-staining of the cytoplasm can be carried out on the slide using several drops of 45 per cent acetic acid. The chromosomes are very clearly seen under both normal and phase-contrast microscopes[5]. It is possible to count and to photograph selected mitotic plates within 5 h from the commencement of this procedure. Permanent preparations can be made in the usual way[2].

Among the genera and families in which this method has proved successful are *Nicotiana* and cultivated tomato (Solanaceae), *Ribes* (Grossulariaceae), *Rubus*, *Fragaria* and *Malus* (Rosaceae), *Brassica* and radish (Cruciferae) and *Daucus* (Umbelliferae). It was found advisable in *Daucus* to fix portions of the umbel without prior removal of buds and dissection of the tiny corollas. Heterochromatic regions were readily seen in this material following cold treatment of the plants. A particular advantage of making chromosome counts from corollas is seen following the treatment of somatic tissues with colchicine to induce polyploidy. Thus it was possible to confirm the chromosome number $2n = 34$ in the diploid apple variety 'Spartan' (from flower buds collected on a dull, wet day); but a strain of this variety received as a colchicine-induced tetraploid proved also to be diploid, so confirming a previous suspicion deduced from floral morphology and stamen number.

Polymorphism in the Serum Proteins of the Reindeer

Polymorphism in the serum proteins of the reindeer was detected in 1959 (unpublished results) in samples collected by me and investigated by Dr. B. Cohen, then at the University of Edinburgh. Gahne and Rendel[1] reported the findings of six different transferrin types which they explained on a basis of three alleles.

In this communication results from investigations of serum samples from 132 reindeer are reported. Of these, 100 came from the district of Jotunheimen and 32 came from northern Norway. The samples were investigated by two different techniques. One was that used for examining horse transferrins[2]: the other was that developed by Kristjansson[3] for cattle transferrins. The two methods led to the same conclusions; but Kristjansson's technique gave more distinct zones. Accordingly, results obtained by using this last-mentioned technique were photographed for demonstration in the present report.

The reindeer sera investigated in this work showed great variation in the β-globulins. Two, three or four clearly recognizable zones or bands were seen. They appeared in a total of 15 different phenotypes of which four were two-band and eleven were three or four bands. To account for these various patterns a hypothesis of six codominant autosomal alleles was advanced, each allele being responsible for two bands. The products of the individual alleles were named: *C*, *E*, *G*, *I*, *K* and *M*, the fastest migrating being *C* and the slowest *M*. In all these six two-band patterns the slowest band was generally considerably thicker and stained more heavily than the fast band. The following combinations of the two-band patterns were encountered: *CC*, *CE*, *CG*, *CI*, *CK*, *CM*, *EE*, *EG*, *EI*, *EK*, *EM*, *GI*, *II*, *IK* and *KK*. Most common were *C* and *E* types, most rare were the *G* and *M* patterns.

In Fig. 1, which is a photograph of a stained gel, the results from investigation of eight selected serum samples are shown. The positions of the albumins, the α- and the β-globulins are marked on the left of the photograph. Because of the special electrophoretic conditions the albumins are condensed into a thick, heavily stained line going across the gel. The α-globulins are thin, indistinct, curved bands. Three of the samples are from animals being homozygous as to β-globulin types. They are *CC*, *EE* and *II*. The five other samples all show heterozygous animals. Phenotypes representing the remaining two-band patterns *G*, *K* and *M* are seen in all of them. The migration rates for the six two-band patterns are clearly different, the positions of the *G* bands, however, being only slightly slower than the *E* bands under the electrophoretic conditions used in these investigations. There is some indication that the *C* bands actually are of two types, the one, which is rare, being insignificantly slower than the common *C* type.

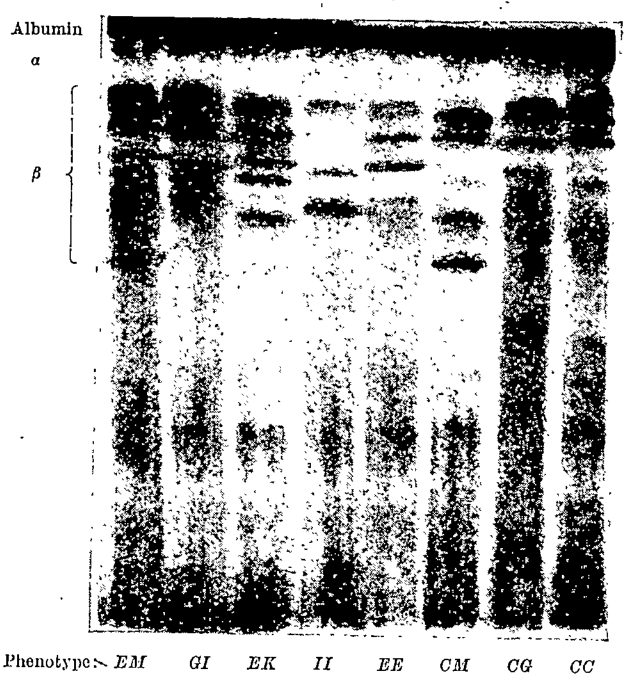

Fig. 1. Photograph of a stained gel showing eight selected reindeer transferrin phenotypes

Besides these different bands in the β-globulin region other but more faint bands or zones may be seen on the photograph, for example, in the samples showing the phenotypes *CC*, *CM* and *EM*. In the first sample there is a faint band in front of the *C* bands. In the two other phenotypes faint bands may be seen between the fastest and slowest two-band patterns of the respective phenotypes. Whether these faint bands belong to the same protein system as those previously mentioned is not known. The occurrence and relative positions of some of these very faint bands in the β-globulin region may, however, indicate that they belong to the same protein system as that already described. This would then suggest that each allele is responsible for three bands or zones.

The serum proteins described by Gahne and Rendel[1] were reported to be transferrins. The proteins dealt with in this work are of a similar type. It is, therefore, concluded that they are transferrins. Accordingly, a genetic theory of six transferrin alleles, Tf^C, Tf^E, Tf^G, Tf^I, Tf^K and Tf^M, is proposed.

I thank Mr. I. Godal, district veterinary officer at Lom, and Mr. S. Skjenneberg, veterinary investigation officer at the State Veterinary Laboratory, Harstad, for their help in securing the samples.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Research Assistant (inclined towards theoretical physics, with a university degree or diploma in technology with first- or second-class honours) in the Department of Mathematics, to work in the field of absolute rates of electrode processes and associated potential distributions—The Principal, Lanchester College of Technology, Priory Street, Coventry (August 14).

Graduate Chemist or Biochemist to work in the metalloprotein field—The Secretary, Institute of Neurology, The National Hospital, Queen Square, London, W.C.1 (August 15).

Lecturer or Assistant Lecturer (with a good honours degree in civil engineering and good general training and experience, and preferably a knowledge or special experience in surveying and photogrammetry) in the Department of Civil Engineering—The Registrar, The University, Leeds, 2 (August 17).

Research Assistant (veterinary or pure science graduate) in Reproduction for research into problems of male fertility—The Registrar, The University, Liverpool, quoting Ref. CV/25/N (August 17).

Research Assistant (with a degree in one of the social sciences) in the Faculty of Social Sciences—The Secretary and Registrar, The University, Southampton (August 17).

Research Assistant in the Department of Sociology—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (August 20).

Lecturer or Assistant Lecturer in the Department of Statistics, to lecture in probability theory or mathematical statistics and carry out research—The Registrar, The University, Sheffield (August 22).

Lecturer (with experience in one or more of the following fields: numerical analysis, systems programming, engineering aspects of computer design including memory systems and electronic circuits) in the Department of Computer Science—The Registrar, The University, Manchester, 13 (August 22).

Research Assistant (graduate with research experience who may read for a higher degree, or with a Ph.D.) in the Department of Physics to work on the application of electron microscopy to the study of ferromagnetic domains—The Registrar, The University, Sheffield (August 22).

Assistant (graduate in pure science, agriculture, or agricultural economics or economics) to the Principal—The Secretary, The North of Scotland College of Agriculture, Crown Mansions, 41½ Union Street, Aberdeen, Scotland (August 24).

Lecturers (2) in the Department of Physiology, University of Ibadan, Nigeria—The Secretary, Senate Committee on Higher Education Overseas, University of London, Senate House, London, W.C.1 (August 24).

Assistant Lecturer (Grade B) in Physics—The Clerk to the Governors, Woolwich Polytechnic, London, S.E.18 (August 27).

Assistant Lecturer in Zoology—The Secretary, The Queen's University, Belfast, Northern Ireland (August 28).

Lecturer in Surgery—The Secretary, The University, Aberdeen (August 28).

Technician (with one of the following qualifications: Ordinary National Certificate in chemistry or equivalent qualifications preferably including chemistry at "A" level) in the Botany Department, to assist with investigations—Prof. D. J. Carr, Department of Botany, The Queen's University, Belfast, Northern Ireland (August 28).

University Librarian—The Registrar, The University, Manchester (August 28).

Assistant Lecturer or Lecturer in Geography—The Assistant Registrar (Arts and Law), The University of Birmingham, Birmingham, 15 (August 31).

Demonstrator in Psychology—The Registrar, The University, Keele, Staffordshire (August 31).

Lecturer (preferably with a veterinary qualification and interested in chemical pathology) in the Department of Pathology—The Secretary, The Royal Veterinary College (University of London), Royal College Street, London, N.W.1 (August 31).

Lecturer (with an honours degree and experience in the design and use of systems involving a digital computer or in some branch of control engineering) in the Department of Electrical Engineering—The Registrar, The University, Leeds, 2 (August 31).

Lecturer (with at least an honours degree or equivalent qualifications, a good general background and postgraduate research experience in some major field of botany or zoology) in Botany or Zoology in the School of Biological Sciences, University of New South Wales, Sydney—The Agent General for New South Wales, 56–57 Strand, London, W.C.2; and The Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, N.S.W., Australia (August 31).

Research Assistant (with a higher degree or equivalent experience) in the Department of Mechanical Engineering, for an investigation of the use of shock tube techniques in the study of non-equilibrium ionization phenomena—The Secretary, University College, Gower Street, London, W.C.1 (August 31).

Senior Lecturer or Lecturer (preferably with special interests, teaching and research experience and/or research qualifications in one or more of the following fields: protozoology; arthropoda other than insecta; herpetology; mammalia; genetics; cytology or freshwater biology) in the Department of Zoology, Ahmadu Bello University, Northern Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (August 31).

Lecturer (with appropriate experience in research and teaching) in Physiology at the University of Hong Kong—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Hong Kong and London, September 5).

Scientific Officer, Zoologist (preferably with an honours degree in zoology) in the Animal Ecology Division Department of Scientific and Industrial Research, New Zealand, to join a small research team working mainly on the basic ecology of ungulates and other introduced mammals in New Zealand—The High Commissioner for New Zealand, New Zealand House, Haymarket, London, S.W.1, quoting Ref. B13/18/26/2651 (September 5).

Staff Tutor in Social Science (with special reference to community tudies) in the Department of Extra-Mural Studies—The Registrar, The University, Liverpool, quoting Ref. CV/249 (September 6).

Assistant Keeper (with an appropriate degree, at least one year's relevant postgraduate experience, and a special knowledge of geology, preferably petrology or mineralogy) in the Department of Geology—The Director, Museum and Art Gallery, New Walk, Leicester (September 7).

Assistant Lecturer (with a degree in mathematics or the physical sciences, and preferably some postgraduate experience) in Computing—The Registrar, University College of North Wales, Bangor, North Wales (September 7).

Lecturer in Chemistry and a Lecturer in Zoology at Njala University College, Njala, Sierra Leone—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (September 10).

Senior Lecturer or Lecturer in the Department of Materia Medica and Therapeutics—The Secretary, The University, Aberdeen (September 12).

Stanley Elmore Senior Research Scholar in the Medical Sciences for research in medicine, preferably in the fields of nutrition or fœtal and neonatal physiology—The Master or Prof. R. A. McCance, Sidney Sussex College, Cambridge (September 14).

Professor of Biochemistry—The Secretary and Bursar, University College, Dublin, Republic of Ireland (September 15).

Chair of Physics as Applied to Medicine at the Institute of Cancer Research—The Academic Registrar, University of London, Senate House, London, W.C.1 (September 23).

Chair of Psychology in the Faculty of Science—The Registrar, The University of Birmingham, Birmingham, 15 (September 25).

Reader in Human Genetics—The Registrar, University of Newcastle upon Tyne, Kensington Terrace, Newcastle upon Tyne, 2 (September 26).

Director of the Closed Circuit Television Service whose responsibilities will include development, organization and administration of the service, interesting and advising academic staff in the uses of television and investigating its place in university education—The Registrar, The University, Leeds, 2 (September 30).

Lecturer (with an appropriate honours degree or equivalent qualifications) in the School of Mechanical Engineering at the University of New South Wales—The Agent General for New South Wales, 56–57 Strand, London, W.C.2; and The Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia (September 30).

Professor of Organic Chemistry—The Registrar (Room 22, O.R.B.), The University, Reading (October 24).

Lecturer (with an honours degree in optometry or equivalent qualifications, some clinical experience, and preferably some teaching and/or research experience) in the Department of Optometry, School of Physics, The University of New South Wales—The Agent General for New South Wales, 56–57 Strand, London, W.C.2; and The Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, N.S.W., Australia (October 31).

Bacteriological Technicians (preferably with experience in handling laboratory animals) to assist in research in food microbiology, including studies on clostridial spores and the application of new enzymic and serological techniques to the detection of pathogenic bacteria in foods—The Director, British Food Manufacturing Industries Research Association, Randalls Road, Leatherhead, Surrey.

Botanist or Chemist (with a second-class honours degree and interested in plant-soil nutrition)—Reader in Soil Science, Department of Agriculture, The University, Oxford.

Chair of Organic Chemistry—The Registrar, The University, Senate House, Bristol 2.

Chair of Zoology—The Registrar, The University, Senate House, Bristol 2.

Chemist or Biochemist (preferably with experience of analytical techniques) to join a team working on human fertility and the causes of fœtal abnormalities—Prof. J. M. Robson, Pharmacology Department, Guy's Hospital Medical School, London Bridge, London, S.E.1.

Experienced Female Technician for a research unit—The Administrator, Department of Biochemistry, The University, South Parks Road, Oxford.

Graduate (preferably with experience of endocrinology) to join a team doing research on mammalian fertility and anti-fertility drugs—Prof. J. M. Robson, Pharmacology Department, Guy's Hospital Medical School, London Bridge, London, S.E.1.

Junior Scientist (with a good honours degree and a biochemical qualification) for the study of protozoal and helminthic parasites of importance to tropical medicine—The Director, National Institute for Medical Research, Mill Hill, London, N.W.7.

Lecturers or Assistant Lecturers (2) (well qualified academically and preferably some teaching, together with research or industrial experience) in Mathematics—The Academic Registrar, Loughborough College of Technology, Loughborough, Leicestershire, quoting Ref. 12/2/G.

Nematologist (national of the United Kingdom or the Republic of Ireland, with an honours degree in zoology or natural science, plus one year's postgraduate training or experience, preferably in the study of nematodes) in Kenya, to carry out research on nematology in relation to crop husbandry—The Appointments Officer, Room 301, Department of Technical Co-operation, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 213/95/03.

Physicist (female graduate) to operate an electron probe microanalyser as a service for various research programmes in the Department—J. A. Charles, M.A., B.Sc., Department of Metallurgy, The University, Pembroke Street, Cambridge.

Physiological or Biochemical Worker for investigating electrical and ionic phenomena in tissues from the brain (micro-electrode and electrophysiological techniques involved)—The Secretary, Institute of Psychiatry, Maudsley Hospital, Denmark Hill, London,-S.E.5.

Plant Breeder (with a degree in botany or genetics, and preferably postgraduate experience in plant breeding) in Northern Rhodesia, to carry through breeding programmes mainly with maize, wheat or ground-nuts, and to produce varieties adapted to Northern Rhodesian conditions—The Appointments Officer, Department of Technical Co-operation, Room 301, Eland Place, Stag Place, London, S.W.1, quoting Ref. RC 213/132/05.

Research Assistant (graduate in microbiology or the biological sciences) in Microbiology, to work on either the production and utilization of algae, or some aspect of food microbiology—Head of the Department of Biological and Health Studies, Battersea College of Technology, London, S.W.11.

Research Assistant (with a Ph.D. or equivalent research experience, and some knowledge of electronics) with a group centred at Silwood Park, near Ascot, working on rocket measurements of magnetic fields in the ionosphere, currently concerned with Centaur and Skylark rockets launched from Woomera and Andöya Is.—Geophysics Department, Imperial College, London, S.W.7.

Research Fellow in the Department of Electrical Engineering for studies in the synthesis of lumped linear electrical networks—The Registrar, The University, Leicester.

Research Fellow (with a good honours degree) in the Physics Department of the United Birmingham Hospitals, to investigate the physical aspects of medical ultrasonics—The Chief Physicist, Queen Elizabeth Hospital, Birmingham 15.

Research Physicist (with a Ph.D. degree or expecting to submit a thesis shortly) in Vacuum Spectroscopy for research which involves the measurement of absorption cross-sections in the vacuum ultra-violet (2000 Å to

400 Å)—The Professor of Physics, J. J. Thomson Physical Laboratory, The University, Whiteknights Park, Shinfield Road, Reading, Berkshire.

SCIENCE GRADUATE BACTERIOLOGIST (Basic or Senior Grade) (with an honours degree) on the staff of the Pathology Department—The Secretary, Birmingham (Selly Oak) H.M.C., Oak Tree Lane, Birmingham, 29.

SENIOR RESEARCH ASSISTANT IN ORGANIC CHEMISTRY, to work on new syntheses of porphyrins with Prof. G. W. Kenner—The Registrar, The University, Liverpool, quoting Ref. CV/243/N.

SENIOR ZOOLOGIST (national of the United Kingdom or the Republic of Ireland, an honours degree in zoology or equivalent, with research or other experience in zoology) IN THE VETERINARY DEPARTMENT, Kenya, for investigations into the treatment of trypanosomiasis, research work in immunity both in the laboratory and in the field, and to give advice on drug regimes in the various areas of the country—The Appointments Officer, Department of Technical Co-operation, Room 301, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 217/95/04.

REPORTS and other PUBLICATIONS

(*not included in the monthly Books Supplement*)

Great Britain and Ireland

The Radiochemical Centre. Catalogue of Radioactive Products: Radioisotopes—Labelled Compounds—Radiation Sources. Pp. 164+13 plates. (Amersham: The Radiochemical Centre, 1964.) [106

Most Significant New Books on Chemistry, 1963: a Bibliographic Guide to New Literature published throughout the World, with Annotations. Pp. 51. (Oxford: Robert Maxwell and Co., Ltd., 1964.) [106

South-West Essex Technical College and School of Art. Annual Report, Session 1962–63. Pp. 40. (Walthamstow, London, E.17: South-West Essex Technical College and School of Art, 1964.) [106

The Royal College of Science and Technology, Glasgow. Annual Report, 1962–1963. Pp. 95. Report on Research, Session 1962–63. Pp. 53. (Glasgow: The Royal College of Science and Technology, 1964.) [106

University of Oxford. Annual Report of the Curators of the Bodleian Library for 1962–63. (Supplement No. 9 to the *University Gazette*, May 1964.) Pp. 43. (Oxford: The University, 1964.) 2*s*. [106

Department of Scientific and Industrial Research. Memoirs of the Geological Survey of Great Britain—England and Wales. The Geology of the South Wales Coalfield. Part 4: The Country Around Pontypridd and Maesteg, (Explanation of One-Inch Geological Sheet 248.) By Dr. Austin W. Woodland and W. B. Evans. Third edition. Pp. xiv+391+8 plates. (London: H.M. Stationery Office, 1964.) 60*s*. net. [106

British Drug Houses, Ltd. Nucleotides and Coenzymes in Metabolism. Pp. 22. Applications of Sodium Bismuthate. Pp. 5. Sugar Phosphates and Related Compounds in Metabolism. Pp. 35. BDH Enzyme Assay Sets. Pp. 3. (Poole: British Drug Houses, Ltd., 1964.) [106

Man and Nature in the New Testament: Some Reflections on Biblical Ecology. By Prof. C. F. D. Moule. (The Ethel M. Wood Lecture delivered before the University of London on 9 March 1964.) Pp. 22. (London: The Athlone Press, University of London, 1964. Distributed by Constable and Co., Ltd.) 4*s*. 6*d*. [106

The Electrical Research Association. Technical Report L/T405: Dipole Moment Fluctuations in a Dielectric Body. By Dr. B. K. P. Scaife. Pp. 14. (Leatherhead: The Electrical Research Association, 1961.) 15*s*. [106

Fifteenth Annual Report of the Lace Research Association, 1963. Pp. 22. (Bilborough, Nottingham: The Lace Research Association, 1964.) [106

Council for the Preservation of Rural England, Sheffield and Peak District Branch. Annual Report, May 1964. Pp. 26. (Sheffield: Council for the Preservation of Rural England, Sheffield and Peak District Branch, 1964.) [106

Central Office of Information. Broadsheets on Britain, New Series, No. 19: Looking Ahead—Agriculture in Britain. Pp. 4. (London: Publications Division, Central Office of Information, 1964.) [106

A Career in the British Pharmaceutical Industry. Pp. 24. (London: The Association of the British Pharmaceutical Industry, 1964.) [106

"Fetch me a Surgeon". By Prof. A. L. d'Abreu. (An Inaugural Lecture delivered in the University of Birmingham on 10th March 1964.) Pp. 16. (Birmingham: The University, 1964.) 2*s*. 6*d*. [106

EDUCATION AND MAN-POWER IN EAST AFRICA

THE basic problem of developing countries is to promote economic development to raise their standards of living. In the past decade or so, there has been a remarkable change from a belief that this can best be achieved by the classical method of heavy capital investment to a belief that investment in people through the development of 'human capital' may provide a surer means of achieving this end. The main instrument of such development is seen to be education. The arguments for such a change have been partly economic, but partly also political. For example, post-war American aid to Latin America has taught the United States a sharp lesson that capital investment and aid for economic development do not necessarily mean raised standards of living for the majority of the population of an emergent country, nor do they necessarily stop the growth of Communism—often, indeed, the reverse may be the case. The United Nations Educational, Scientific and Cultural Organization has preached the doctrine (though on what basis it has never been quite clear) that education is a basic human right to which all people are entitled. The people themselves of the developing countries have become utterly persuaded that, more than anything else, education holds the key to their future prosperity and progress. As if to confirm their belief, some of the older countries, more particularly Britain, have in late years also become converted to a similar philosophy on their own domestic scenes.

Education in developing countries, therefore, is now a field of considerable importance and the subject of much thought and planning. Even so, the literature on it is surprisingly sparse, and nowhere is this more so than on the man-power and planning aspects. This makes particularly welcome a recent book giving a detailed case-study of educational opportunity in a developing area, namely, East Africa*. The study represents, in fact, the first stage of a larger project undertaken by Political and Economic Planning with the aid of a grant from the Ford Foundation of America, the main purpose of which was to analyse the conditions which oversea students (particularly Africans) meet during their studies in Britain; the degree to which their courses fulfil their needs and aspirations, and some of the difficulties involved in providing a bigger flow of British teachers to overseas countries. In the words of Mr. Guy Hunter, its author, it is "a detailed case-study of the actual day-to-day problems of educational opportunity in a particular area—the stubborn facts from which wider strategy must be planned". As such, it is most likely to interest the educational planner, but there is also much food for thought in it for all who take an interest in the East African scene.

Several problems stand out starkly in this book, but in no case can they be described as purely East African problems. They are common to the whole of former British Tropical Africa. Undoubtedly, the most important is what is to become of the vast numbers of schoolchildren who will finish their primary education in the next few years and for whom no secondary schooling will be available. After independence, some African countries introduced universal primary education, but all, including the East African countries, had greatly increased the provision of primary school places even before that event. In future years these hordes of frustrated children leaving primary school may well constitute potentially the biggest source in their countries of social and indeed political unrest. However, it is not likely that this problem will be seen by East African Governments as their major educational priority; this will undoubtedly be reserved for secondary education. While the most optimistic forecasts in East Africa over the next few years envisage the possibility of secondary education for 10 per cent of the primary school population, the reality is much more likely to be nearer 6 per cent, a figure which is totally inadequate to meet the higher man-power needs of these newly independent countries. There is no doubt that East African Governments see as their main problem that of replacing expatriates in the public services and obtaining enough local people at least to take a hand in the private sector of the economy and to direct and administer their programmes of economic development. For them therefore above all it is the output of the secondary schools which matters—it is those schools which will produce the teachers which will make the further expansion of secondary education possible and also provide the future agricultural extension workers for the development of agriculture, East Africa's basic industry. So pitifully inadequate will the output of secondary schools be until 1966 that it will not meet even wastage and the lowest economic growth rate over the present. In Kenya in 1961, for example, 182,227 children were enrolled in the first year of the primary school. In the same year only 1,054 were in the fourth form (School Certificate year) of the secondary school. Of these only 540 sat the School Certificate examination and far less passed. The greatest scarcity is undoubtedly that of qualified secondary school teachers, particularly scientists, and the shortfall here will have to be made good by the recruitment on contract of expatriate 'experts', especially to fill the gaps created by the recruitment of African graduates for other spheres of the national life than teaching. Supplying such temporary graduate teachers may well be the greatest contribution that Britain can make at this stage towards helping Kenya, Uganda and Tanganyika in solving its urgent man-power problems.

The greatest problem of all in East Africa, however—and Mr. Hunter's greatest dread—is the possible lowering of educational standards, more particularly at the secondary school and university levels, through indiscriminate and unbalanced expansion. If standards fall at the secondary level, fewer and fewer people will secure the necessary entry qualifications for admission to universities abroad (especially in Britain) or at home, and this could have a disastrous effect on top-level administration and the public service. However, if present standards are maintained the output of the system is patently inadequate to meet present or future needs. The answer, he believes, is to make better use of those post-School Certificate candidates who do not obtain the necessary qualifications to proceed to a university, and at the same time to upgrade after training those people with experience but lacking the paper qualifications who have demonstrated their ability in the various aspects of the national life. A recent educational tour of East Africa showed that Mr. Hunter's worst fears in regard to secondary education are, in fact, already coming true, more particularly in Kenya. There, despite the acute shortage of qualified teachers, and technical facilities such as adequate science laboratories, local government authorities are defying advice from the central government and are setting up —primarily for prestige reasons—their own local, one-stream and inefficient secondary schools. There is every indication that in East Africa this tendency will grow; if it does, educational standards will inevitably fall.

---

* *Education for a Developing Region; A Study in East Africa.* By Guy Hunter. Pp. xvi+119. (London: George Allen and Unwin Ltd., for Political and Economic Planning and the Institute of Race Relations. 1963.) 20*s*. net.

Mr. Hunter's solution to the problem of making the greatest use, from a man-power point of view, of post-School Certificate candidates who do not proceed to a university but who enter the economy directly without training is much more debatable. In many developing countries in the Commonwealth novel solutions to the problems of such training and higher education have been devised by the setting up of institutions which owe much to the American idea of the junior college and the liberal arts college. Mr. Hunter sees in such institutions his dreaded bogy of lowered educational standards and he will have none of them. Instead, he would provide diploma and up-grading training in already existing institutions. He is led, equally, to defend the institution of the sixth form, which would inevitably suffer if such new post-School Certificate colleges were set up, since their entry qualification is often a reasonable grade of School Certificate or five Ordinary Level passes in the General Certificate of Education. Senior African opinion in East Africa is strongly in favour of the junior college idea, and African administrators, with hard-headed realism, feel that such a college could do far more to supply diversified training to feed the needs of the economy than the present system. Moreover, the University of East Africa has recently invited the former registrar of the University of the West Indies, a man with much experience of the college idea, to advise it on this matter. The recent report on university education in Malawi has recommended a university which recruits at Ordinary Level or School Certificate, as also has the Lockwood Report on the Development of a University in Northern Rhodesia, a report which has already been accepted by that Government. It is scarcely likely, therefore, that East Africa will depart from such a general pattern, in spite of Mr. Hunter's persuasive arguments. Perhaps the answer to his dilemma is for East Africa to adopt the West Indian model of a post-School Certificate college where diploma-type courses in a variety of subjects will be provided for those who do not have the ability to proceed further to take a degree, while, at the same time, the door is kept open for the later transfer to a university for those who do.

The recent Commonwealth Prime Ministers' Conference in London, with Sir Alexander Douglas-Home's suggestion for further United Kingdom co-operation and assistance in the field of higher education, highlights the importance of many of the themes Mr. Hunter discusses in this book. For this reason it should be read by all who are interested in the development of education, not only in Africa, but also in the younger countries of the Commonwealth.

THE ENERGY OF SCIENCE

Little Science, Big Science

By Derek J. De Solla Price. Pp. 119. (New York and London: Columbia University Press, 1963.) 33*s.* 6*d.*; 4.50 dollars.

THIS is a small but very important book. Based on the George B. Pegram Lectures at Brookhaven National Laboratory (June 19–29, 1962), it contains essays based on one guiding idea—to apply scientific method to the whole structure of modern science itself and thus help to create the new science of science, based not on abstract theory but on actual observations.

Price is attempting to do for science what the pioneers Petty and Graunt tried to do for economics and population in the seventeenth century with a *Political Arithmetic* and *Remarks on the Bills of Mortality*. But, as science deals not so much with heads of population or pounds of goods but with men's intelligence, the science of science also involves a study of that distribution of intelligence which was begun in the nineteenth century by Galton. In modern science numerical analysis can show that, however much individual initiative and genius play in the details of scientific discovery, the whole fabric of science compounds these different initiatives and produces, by a kind of statistical mechanics, ascertainable laws of growth which can be observed in the past and projected into the future. This is, of course, only one aspect of a science of science. It furnishes limiting conditions, size and rate of growth of science as a whole. Price touches also on the other aspects in his latter chapters: the effects of science on social and economic development; the resulting effects on the scientists themselves.

The growth of science in numbers and in cost has been so spectacular in the past twenty years that it appears to be qualitatively different from anything that has gone before. Price is at pains to point out that this is an appearance which any rapidly growing human activity would present at any point in its history. We are informed that 80–90 per cent of all scientists who have ever lived in the world are alive now. This, he points out, would have been just as true in 1900 as it is to-day; but this now presents a qualitative difference—we now feel we are in the new period of "Big Science". The quantitative growth that preceded its appearance has been overlooked in the mass of the monster we have created. The image of the 'little scientist' of the past is romanticized as that of the 'big scientist' of the present is being magnified and coarsened. According to Price:

> ". . . the transition from Little Science to Big Science was less dramatic and more gradual than appears at first. For one thing, it is clear that Little Science contained many elements that were grandiose. And, tucked away in some academic corners, modern Big Science probably contains shoestring operations by unknown pioneers who are starting lines of research that will be of decisive interest by 1975." (P. 3.)

But the essential feature both of 'little science' and 'big science' is the very rapid exponential growth, greater than that of population and that of the economy, doubling every 10–15 years.

This we have long known: where Price breaks new ground is by relating it to other factors particularly the quality, the supply of scientists and the cost of science. Exponential growth measured by the rate of production of scientific publications has scarcely altered even after the great catastrophes of our time. Wars and economic depressions set the curve back by about five to ten years. Then it goes on rising along the same line. Thus, Price has pointed out elsewhere in *Science Since Babylon* (New Haven, Yale University Press, 1961), that exponential rate of growth would produce more scientists than people within two centuries, and this is not going to happen.

Until now the exponential rate has been well maintained. But Price points out that a closer analysis shows that in the advanced countries it is already effectively at an end. The character of any exponential growth in a natural system is to turn over into a so-called logistic curve, an S-shaped curve rising to a certain saturation maximum. He musters evidence to show that the turning point is not somewhere in the near or far future but, for the advanced countries, has already arrived. The symptoms of this are the occurrence of sudden fluctuations; the rising curve is only maintained by bursts and escalations, such as those which occurred in the development of high-energy particle accelerators. Ultimately it is checked by the apparent shortage of trained workers needed for the largest scale of operations.

> "Such an analysis seems to imply that the state called Big Science actually marks the onset of those new conditions that will break the tradition of centuries and give rise to new escalations, violent huntings, redefinitions of our basic terms, and all the other phenomena associated with the upper limit. I will suggest that at some time, undetermined as yet but probably during the 1940's or 1950's, we passed through the mid-period in general logistic growth of science's body politic." (P. 31.)

Here it seems to me that Price is putting forward extremely interesting but not altogether well-founded conclusions.

Going back to Galton, he further considers the distribution of eminence among scientists, the distribution of which, according to a law due to Lotka, is as the square root of the whole number. This law fits very closely the distribution of ability of scientists using the somewhat suspect criterion—but the only one available—of the number of papers published in a working life. He concludes that for a hundred authors publishing only one paper, there will be two who will produce one-quarter of the papers, ten will produce half and the rest will produce the last quarter. This would seem to discount the effect of the single shot genius, while it magnifies the influence of the number of dullards with an itch to write. Nevertheless, it may be quite adequate for statistical purposes. It would not be far wrong to say that the number of average men goes up as the square of the good ones. So that the number of scientists, which doubles every ten years, corresponds to the number of noteworthy scientists who double only every twenty. The number of potential scientists gauged as Ph.D.s shows some relation to the distribution of intelligence quotients of the population. In the United States, where education for the most intelligent is most widespread though by no means ideal, for one Ph.D. in every 300 of the population, intelligence quotients range from 140·3 for physicists down to 123·3 for educationalists. This is essentially prestige selection: education is a much more difficult as well as more essential field than physics.

At that point Price goes over to the consideration of the even or uneven distribution of scientists, particularly good scientists:

> ". . . science displays in several ways a tendency to crystallize out, in the sense that big things grow at the expense of the small ones that constitute a sort of mother liquor. Large fields seem to absorb the manpower and subject matter of small ones. Even though new fields, new departments, new institutions, and even new countries arrive on the scientific scene in increasing number, the few previously existing large ones have a natural growth enabling them in general to maintain their lead." (Pp. 56–7.)

> "About this process there is the same sort of essential, built-in *undemocracy* that gives us a nation of cities rather than a country steadily approximating a state of uniform population density. Scientists tend to congregate in fields, in institutions, in countries, and in the use of certain journals. They do not spread out uniformly, however desirable that may or may not be. In particular, the growth is such as to keep relatively constant the balance between the few giants and the mass of pygmies. The number of giants grow so much more slowly than the entire population that there must be more and more pygmies per giant, deploring their own lack of stature and wondering why it is that neither man nor nature pushes us toward egalitarian uniformity." (P. 59.)

In his third section, Price considers the actual organization or fragmentation of science, particularly in the field of scientific publication. He points out that we are right back in the stage reached by science in the early seventeenth century, but for opposite reasons; previously it was because there were too few scientists, now because there are too many to keep in touch with each other even by publication. A solution has been found in the presence of 'invisible colleges'—the people in the forefront of their own subjects who all know each other and communicate by letter or by direct personal contact, following what he calls the 'high grade and affluent scientific commuter'. This somewhat chaotic development leads to the persistence of multiple discoveries, in fact to its increase. According to Price, premature publication had its *raison d'être* in earlier times as a way of achieving priority but failed to prevent numerous disputes. He thinks that "Scientists have a strong urge to write papers but only a relatively mild one to read them".

One way out of the present plethora of science is the publication of papers by a multiplicity of authors. The latter practice is growing so rapidly that it looks as if the single author paper will disappear in a few years.

> ". . . There is a continuous movement toward an increase in the productivity of the most prolific authors and an increase in the numbers of those minimally prolific. As we approach a limit in both directions, it is clear that something has to give. The most prolific people increase their productivities by being the group leaders of teams that can accomplish more than they could singly. The minimal group are in short supply and we can hardly afford to let them grow until they reach that ripeness of producing significant papers on their own." (Pp. 89–90.)

> "Because of this, one of the great consequences of the transition from Little Science to Big Science has been that after three centuries the role of the scientific paper has drastically changed. In many ways the modern ease of transportation and the affluence of the élite scientist have replaced what used to be effected by the publication of papers. We tend now to communicate person to person instead of paper to paper." (Pp. 90–91.)

Nevertheless, papers can be used to some extent as the measure of the quality of scientific work. The effective value of a paper, by the measure of how much it is read or at least the ascertainable measure of how often it is cited, is a quantity that can now be determined numerically in the new *Science Citation Index*. The degree of citation gives Price an indication of the quality more or less corresponding to the quantity criterion previously made. Price does not claim this as saying anything about the value of the contribution of individual scientists but only the statistical mechanics of scientific man-power and literature which he finds obeying the same general laws.

Surveys of readership show, for example, that the half-life of the scientific paper is in many fields of the order of the doubling time in the subject, which would mean that the probability of being read in any given field remains constant, a rather surprising result which would certainly never hold for physics, where the half-life is only two-and-a-half years. But, as Price points out, in physics the rapidity of publication, with its immense back citation, multiplies the overlapping of discoveries so that much of its apparent growth is fictitious.

> "All this makes for considerable change in the motivation of the scientist; it alters his emotional attitude toward his work and his fellow scientists. It has made the scientific paper, in many ways, an art that is dead or dying. More than this, the invisible colleges have a built-in automatic feedback mechanism that works to increase their strength and power within science and in relation to social and political forces." (P. 91.)

These changes indicate to Price something of the qualitative nature of the change from 'little science' to 'big science'.

In his final and in some ways his most important chapter, Price discusses political strategy for 'big scientists'. Here his outlook becomes international rather than national. He has previously indicated the factors that tend to stagnation, but here he goes further to show that this is due to the fact that in 'big science' the cost of science varies not as the number of scientists but as the square of that number; effectively it tends to bring down the rate of increase of science mitigated only slightly by the importation of scientists from other countries.

> "... the suggestion that this is the cybernetic feedback that is now trying to decelerate science and bring it to a maximum size. This, we maintain, is the prime cause of the present logistic rather than exponential curve. This is the difference between Big Science and Little Science." (P. 94.)

Looking at the world as a whole, it is evident that only a few countries have reached this stage; in fact, strictly, only one—the United States. More than three-quarters of the world science has no large part to play either in education or in utilization. Yet it is in developing countries that it can grow most rapidly because they alone possess large untapped reservoirs of human ability. Price shows that in the past fifty years the balance of scientific effort of the different countries has varied enormously. But while those of the old countries have remained either approximately constant or actually decreased, as has that of France and Germany, that in the countries which have successively entered the scientific world have increased. In the United States, which came in first, the increase which started in the 'eighties has gradually worn itself down to a static condition. The countries with still growing increases are Japan, the Soviet Union and now China.

Once, whether for economic or political reasons, the 'brain drain' of scientists comes to be checked, as is likely in the field of science in the first place, the gap between the rich and poor countries will be filled. When a more or less even level is reached the total productivity of science will be reasonably held at something like five times what it is now. In the event it may even be more; we are, even in the most advanced countries, far from selecting scientists according to their ability out of the general population. An interesting study of the growth of science in Japan shows that it proceeds by a kind of infective mechanism; 15 physicists, for example, sufficed to produce, in a generation from 1868, 60 by 1900 and several thousands now.

At the end of the book Price discusses the effect of these great changes on the scientists themselves and on the image of the scientist in 'big science' and 'little science'. The catching on of the military usefulness of scientists is going to force them willynilly into positions of political responsibility, a kind of feedback between the effects of the scientist on society and the effect of society back again on the scientist.

Power has passed in its different phases to the military, to the financiers and to the lawyers: now it is the scientists' turn.

> "I hope it is not overdramatic to compare the present position of our scientific leadership to that which has existed in other countries, and in this country at other times, among the groups that used to control the means of destiny." (P. 111.)
>
> "In a democracy we are accustomed to finding the leadership taken by men emerging from all these fields that have been crucial to the world's destiny." (P. 112.)
>
> "This is the credit side of the register which balances some of the other, not so good, changes already noticed in the first generation of new-style Big Science. The scientist is accepted by society and must shoulder his responsibility to it in a new way. The rather selfish, free expansion by exponentially increasing private property of scientific discoveries must be moderated when one is in the logistic state. Racing to get there before the next man might well be, in the long run, an impossibly irresponsible action." (P. 113.)

The great merit of Price's book and the reason why it should become compulsory reading for every scientist, 'big' or 'little', is that the statements it contains are based on facts of observation, not on pre-judgments or wishful thinking. His conclusions can be disputed, but it must be disputed henceforth in his terms, that is, in quantitative terms, using science itself as an object for scientific study.

J. D. BERNAL

MEANING IN PHENOMENOLOGY

Edmund Husserl's Theory of Meaning

By J. N. Mohanty. (Phaenomenologica, Nr. 14.) Pp. ix + 148. (The Hague: Martinus Nijhoff, 1964.) 15.30 guilders.

EDMUND Husserl's Theory of Meaning is an able commentary on a particular part of Edmund Husserl's work, namely, his philosophy of thinking and meaning. The author is an Indian professor with wide post-graduate experience in Germany, and thus well fitted for his task. He sets about it by elaborating his theme as follows: 1, analysis of thought; 2, expression and its functions; 3, thinking and meaning; 4, Husserl's philosophy of language; 5, certain associated problems; 6, formal logic; 7, back to experience.

From this scheme, it is evident that the development of logic and semantics since Husserl's day (he died in 1938) has profoundly modified certain aspects of the whole of phenomenology, and that such progress has been critically assessed. The remarkable feature is how closely several recent advances have been anticipated. Husserl was trained under the formidable influence of Weierstrass (though his original thesis was never published), and he retained through his life a large measure of respect for mathematical modes of thought, even if he seemed to follow his own type of subjectivity. Nevertheless, he was hopeful that Hilbert's meta-mathematics would save the day, a view destined to be disappointed by Gödel's classic paper of 1931; a result which only goes to show how fast events were moving in the master's lifetime.

In my opinion, the most valuable part of the volume is to be found in Chapter 7, wherein the discipline of experience is fully manifest. Paragraph 22 is worthy of special comment. Husserl pondered deeply on the technical and symbolic character of the natural sciences, and the tendency of these to increase with time. He thought of such movements as emptying the subject of much of its meaning. Originally, no doubt, there was much truth in this. The crisis (to use Husserl's own word) may have occurred quite unobserved when Thales, fully aware that geometry had proved itself very useful for mensuration in Egypt, started to ask why it worked at all, and what its success implied. It then became obvious that crude need had produced the science of pure geometry.

Following this train of thought to a period nearer our own, there can be little doubt that, as we are reminded on p. 138, Galileo's quantitative physics did more than he knew to divide sense-data from formal explanation, even though he is commonly regarded as its founder of modern experimental philosophy. In its extreme present-day abstraction, physics has wandered a long way from what Husserl would have accepted as experience.

A closely allied topic is that which Husserl liked to call the 'notion of horizon'. For him, this divided into two, outer and inner. The latter appears not only as giving an object the capacity to be more fully determined than at first sight, but also it actually indicates the possibility of achieving such closer analysis. The former, the outer horizon, posits other co-objects of the same field, and they too are at least capable of experience. It is in passages such as these that Husserl displays an instructive sympathy for psychology, including the integrative principle of the Gestalt concept, and problem pictures with their differing degrees of mental awareness.

This is not an easy book to read. The style is difficult in itself, and encumbered with a veritable plethora of exclamation marks. In addition, the author has the tiresome habit of writing 'if' when he means 'whether'.

All in all, this is a welcome new member of the *Phaenomenologica* series, and exhibits Husserl as a precursor of much that is fundamental in modern logic.

F. I. G. RAWLINS

CHURCH AND STATE

Transactions of the American Philosophical Society

New Series—Vol. 54, Part 1: Rome and the City of God: an Essay on the Constitutional Relationships of Empire and Church in the Fourth Century. By Prof. Karl Frederick Morrison. Pp. 1–56. (Philadelphia: The American Philosophical Society, 1964.) 1.50 dollars.

CHRISTIANITY started as a Jewish sect in Palestine. For its members, the Jewish law was obligatory and the outlook on the world in general and the Messiahship of the Founder was Eastern, Syriac and not Greek. Greek thought started with the cosmos and sought to understand human life (and God in relation to life) from the cosmos; Syriac thought started from the idea of the Living God and sought to understand human life in the cosmos from its vision of God.

Palestinian Christianity was largely destroyed during the wars waged by Titus, but previously had taken root in a number of gentile settlements. Not a few missionaries, including Saint Paul, helped in this dispersion of its beliefs. Maybe, too, some gentiles who had been influenced by the new thought, and had been driven out of Jerusalem at the time of the riots which led to the death of Stephen, also played their part in the spread abroad of the new religion. But the gentiles were Greek in thought and certainly were not interested in Jewish laws. After a hard fight, Saint Paul persuaded the Jerusalem Christians to relax most of these laws and practices including, especially, circumcision. However, the problem of making intelligible the essentially Syriac ideas to the Greek mind remained, as well as the organizing of the several little groups of believers into a Church. The latter problem was solved early, indeed before A.D.180, as the Roman Empire could be used as a model by such organizers as Ignatius and others. The Church they built up was flexible enough to allow for expansion and indeed lasted until the time of the Reformation.

The problem of translating Syriac thought into Greek terms was another matter and involved much controversy. Heresies also arose (especially the Arian in the fourth century), and these complicated the problem. The main question was: What was the nature of the Founder and how could it be expressed in words ? It was not until the fifth century that a solution to the problem satisfactory to the majority was attained at the Council of Chalcedon.

When Constantine the Great was converted to Christianity and the Roman Empire became nominally Christian in the middle of the fourth century, still another vital problem arose: What should be the relationship between the State and the Church, which, by definition, already had the Founder as the divine Head? On one hand, the State did not want an *Imperium in imperio*; on the other, the Church obviously should not be controlled by the secular arm. The idea of the 'City of God' emerged and, with safeguards, a duality grew up which lasted throughout medieval times—the spiritual arm, the Pope; and the secular arm, the Emperor. In this connexion the influence and ideas of Saint Athanasius, of Saint Hilary and, a little later, of Saint Ambrose were vital, and Prof. Morrison, in *Rome and the City of God*, considers them in some detail. If the new Church had fallen completely into the hands of the State, humanly speaking it would have died with the Roman Empire, especially in the West. As it was, the opposite occurred and the early Popes inherited much of the power and influence which had previously been wielded by Rome.

Of course, the problem was not settled for all time in the fourth century; the relationship in France between the Church and the State is still uneasy, and the British solution, where the State appoints the chief church officials but then allows them liberty of action, does not appeal to everyone. Prof. Morrison starts with an introduction and then deals in detail first with the legal principles and later with the theological problems involved. The result is a learned work of great interest, but the general reader should have some knowledge of the subject as a whole before tackling it.

M. C. BURKITT

HEAT TRANSFER

Chemical Engineering Practice

Vol. 7: Heat Transfer. General Editor: Herbert W. Cremer. Pp. vi + 460 + xiii. (London: Butterworth and Co. (Publishers), Ltd., 1963.) 100*s*.

VOLUME 7 in the series *Chemical Engineering Practice* covers the ground of heat transfer, a field of major importance in chemical engineering. Four chapters, which form the greater part of the text, are devoted to heat transfer and are followed by two chapters on drying and a final chapter on heating and ventilation.

The first chapter, by Dr. Franklin and Mr. Hartland, on conduction, forms an extremely good introduction to the basic mechanism of heat transfer and provides a general introduction to the text. The authors have succeeded in discussing both steady- and unsteady-state conditions and two-dimensional flow, but there is a somewhat hurried look about parts of the explanations, and the inclusion of a number of worked examples illustrating the techniques would have been valuable to the practising engineer.

The next three chapters, on transfer by convection, by boiling and by radiation, which have been written by Prof. Roberts and Mr. Cass from the Houldsworth School at Leeds, form the most extensive section of the book. The chapter on convection is well presented and the importance of this mode of transfer is well brought out, but there are sections, such as heat flow in annuli, where a more detailed account of the problems would have been appreciated by the reader. The authors have been reluctant to be in any way definite in recommending particular expressions for the calculation of the heat transfer coefficients under varying conditions, and more on the expected accuracy of such correlations would have helped. The use of packed beds for reactors and the ever widening application of the fluidized bed technique are examined, but more information on the performance of large units would have helped the designer, who is at present uneasy about the application of data from small units. There is much research in this field, but the precise mechanism of heat transfer and the problems of geometry have not yet been cleared for accurate design.

Chapter 3, on heat transfer with phase change, deals extensively with evaporation and boiling, but some of the more recent correlations on nucleate and two-phase transfer should have been included. The designers here are perhaps more concerned with heat flux, and the problems of reproducibility and steady values, than with trying to obtain exceptionally high values of transfer coefficients. Some of the practical features of the desirable extent of vaporization, either per pass in a tube or per cycle in a reboiler, have been treated rather thinly. The authors have made a good attempt at condensing our theoretical ideas, but have left the reader undecided regarding application of the theories. The problems of maximum flux and of burn-out have been of vital consideration in the development of nuclear reactors, but neither these nor the question of high fluxes obtained with rockets and sub-cooled boiling are given much coverage.

Chapter 4 covers the less well analysed field of radiation and will undoubtedly prove of real value to all concerned in work at high temperatures and with furnaces. There is plenty of material here for the thinker, and the chapter well deserves study. Our knowledge of the problems of the drying of solids is still sketchy, and Dr. Nissen and Mr. Macmurray have given a useful summary of the position, but the growing importance of spray drying and the use of fluidized bed dryers are not sufficiently outlined. There is a little duplication here of the principles of heat transfer which are discussed in the first chapter, but with a wide range of authors this may be helpful. A good account is given of the drying of paper on a series of cylinders and this provides an excellent indication of the difficulty in applying theoretical expressions to practical problems. Some good drawings of industrial drying plant would have given the reader a clearer picture of the engineering nature of the units, and a discussion of the cost of drying by various methods should have been included to give the practical engineer a guide to the economics of the operation.

The final chapter, on heating and ventilation, is a welcome addition, which has not been included in the chemical engineering field to any great extent in the past.

This book contains a very useful summary of our present knowledge on the basic principles of heat transfer, but it would have been pleasant to report that there were a large number of worked illustrations from practice. These would embody the kind of information which is lacking in literature to-day, and, although it is clearly difficult to be precise, some real attempt to bring home the difficulties of practice might well have been attempted.

The design engineer is eager for illustrations of the right method for use of techniques, and the more abstract the mathematical methods, as with those on unsteady state processes in Chapter 1, the greater the need for confirmation, by example, that those methods are not only reasonably accurate, but well worth while if better plants are to be designed. J. M. COULSON

VACUUM FOR THE TECHNICIAN

Vacuum Technology

By Prof. Andrew Guthrie. Pp. xii+532. (New York and London: John Wiley and Sons, Inc., 1963.) 94*s*.

INTENDED primarily for the technician, this useful book covers most aspects of vacuum technology excluding applications. Very little background knowledge is assumed of the reader; the text is illustrated by good line-diagrams and photographs and is lucidly written, though the author does exhibit occasionally the disconcerting habit of writing very long paragraphs containing unexpected changes in ideas.

Attractive features of this volume are the many worked examples, the carefully selected tabulated data, the repeated emphasis on experimental procedure and correct operation of plant and the useful chapters entitled "Cleaning Techniques" and "Some Fabrication Techniques".

The text is reliable and with a welcome correct use of terminology. However, some controversial points and errors worth mentioning with the view of being helpful and also indicating the treatment adopted are the following. On p. 42 appears the statement, "If it were possible to connect the inlet of a pump directly to the vacuum vessel then pumping speeds at the vessel would be given directly by the speed curve of the pump. In practice, this is not possible, simply due to space considerations". In fact, this direct connexion is practised, as, for example, in connecting an oil diffusion pump to the base-plate of a vacuum coating chamber. Admittedly here an isolation baffle valve is generally desirable between the pump and the chamber and this will reduce the speed, but it is not "space considerations" which are the difficulty. In some cases, for example, the widely used equations (2·8) and (3·2), a formula is given without proof, which is undesirable where the deduction is simple, especially in view of the author's commendable emphasis on an understanding of elementary kinetic theory in the early chapters. Occasionally, the author's clarity of exposition deserts him, as in Fig. 3·2, where the operation of gas-ballast would not be understood in relation to the accompanying text. Errors occur on p. 53, where division by 28·3 becomes equivalent to multiplication by 0·353, in the statement of Example 1 on p. 63 and in the instructions about cutting off the heater on p. 105. The operation of the Becker molecular pump is not clear from the diagrams and description, and the use of a modulator electrode in the Redhead version of the Bayard–Alpert gauge is not explained. It is surprising to see emphasis given to the X-ray limitation of the Bayard–Alpert gauge without it being stressed in describing the conventional hot-cathode ionization gauge. It is difficult, in view of the problems of temperature measurement and inadequate knowledge of accommodation coefficients, to make the Knudsen gauge an absolute instrument as is implied on p. 187.

In many respects this book can be strongly recommended for the technician, and the scientist or qualified technologist will find much useful information in it. The text could have been made shorter by omitting such data as explanations of decimals, simple index notation, logarithms, rather elaborated numerical work in answer to examples and simple physics amply detailed in British text-books for the Ordinary Level of the General Certificate of Education. A shorter text would also have been beneficial in reducing the rather high price.

J. YARWOOD

HOW CLOTTING BEGINS

The Contact Phase of Blood Coagulation

By H. L. Nossel. Pp. xv+160. (Oxford: Blackwell Scientific Publications, 1964.) 35*s*.

UNTIL recently the investigation of the biochemistry of blood coagulation has depended almost entirely on measuring the time between an experimental manipulation and the appearance of the fibrin clot, together with great ingenuity in varying the manipulation. Thus, in *The Contact Phase of Blood Coagulation*, Dr. Nossel writes (p. 2): "The occurrence of the fibrin clot is the only stage of the clotting process which can be directly observed. All knowledge of preceding stages has been inferred from changes in the rate of fibrin formation". Dr. Macfarlane has recently suggested (*Nature*, 202, 498; 1964) that the existence of a long series of reactions leading to blood clotting has a biological purpose, by acting as a biochemical amplifier system. If this is so, it implies that, the earlier a reaction in the sequence, the smaller the amount of chemical change that occurs in it. Progress in coagulation research will, presumably, largely depend on establishing the biochemical nature of the earlier reactions and on making them measurable.

This book describes experiments in which, as usual, the indicator of what is happening is the clotting time. However, Dr. Nossel has used great ingenuity to contribute to our knowledge of the earliest stage of clotting, that is, 'the contact reaction'. This is a demonstrable interaction between 'foreign surfaces', on one hand, and 'contact factors' present in the blood, on the other. The contact reaction ultimately leads to the coagulation of the blood.

So far as normal blood and this research on it are concerned, the only thing that is not a 'foreign surface' is normal vascular endothelium. All other surfaces are foreign, and they may be divided into those that are relatively inert and those that are actively clot-promoting. Examples of inert surfaces are those made of polythene or of glass treated with silicone. Clot-promoting surfaces include those of untreated glass, kaolin, and 'Celite'. The 'contact factors' in normal blood are called Hageman factor and *PTA* factor. When they are absent from blood, the contact reaction does not occur in it; this can be shown and can be used to differentiate blood deficient in these factors from normal blood.

The first chapter summarizes what was known up to the time of the author's own work about the relation between the contact system and the blood-clotting process. The second chapter deals with the relation between different surfaces and the contact system in the blood. The contact system must be 'activated' by contact with an 'active' surface. Activation is a change which can so far be demonstrated only biologically, not chemically. It may involve only minute amounts of material and is, moreover, probably very evanescent.

With the aid of 'Celite', Dr. Nossel has shown that *PTA* factor can be removed from normal plasma leaving Hageman factor behind. Both factors are necessary in the contact reaction to initiate clotting. A 'contact reaction product' is formed which can be eluted from 'Celite'. This new observation suggests an opening into the chemical investigation of this product unless its amounts are just too small. Dr. Nossel also presents evidence that the contact factors can be activated by pure sodium stearate; this is the only substance present in normal human blood known to be able to do this.

With the aid of these observations, Dr. Nossel then investigates the clinical features and establishes the laboratory diagnosis of patients deficient in contact factors. He shows that the contact product activity formed is related directly to the amount of *PTA* factor in the blood. From this and Ratnoff's earlier work it is concluded that the contact product is formed in two stages: in Stage 1, Hageman factor is activated by an active surface; and, in Stage 2, the activated Hageman factor reacts with *PTA* factor to form the contact product. The latter is inactivated by normal plasma. An ingenious extension of the thromboplastin generation test is used to show that the contact product reacts with Factor IX (Christmas factor) but not with any of the other known clotting factors. This demonstration represents the link of the new to what was known before.

In his final chapter, Dr. Nossel considers the relevance of his findings to hæmostasis and to thrombosis, and the crucial and controversial problem whether or not the contact reaction which initiates blood clotting *in vitro* is also involved in initiating thrombosis *in vivo*. The evidence suggests that there are two alternative mechanisms for initiating clotting, one involving tissue fluid and the other the surface contact surface. Deficiency in one system may be compensated for by normality of the other, but sometimes this compensation fails. Dr. Nossel considers the evidence concerning the role of stearate in the blood. Some time ago Esnouf and I observed that, during clotting, some of the lecithin in plasma is rapidly broken down to glyceryl phosphoryl choline and fatty acids including, presumably, stearate. This and Dr. Nossel's results make it conceivable that the contact system may be activated autocatalytically.

The book is written in the language of the blood-clotting community and has a useful glossary of technical terms. One should perhaps criticize the uncritical acceptance of that language which has acquired bad habits with terms such as 'non-contact plasma' or 'non-contacted plasma'; 'celite exhausted plasma'; 'Hageman factor deficient serum', etc. The use of adjectival nouns may be short and accurate, but it is very displeasing. It does not seem impossible to express these concepts more acceptably with the aid of prepositions. A virtue of the book is the detailed description of experimental procedures; this should allow anyone to use the techniques described. The book should be read by all who are interested in understanding blood coagulation and related phenomena and who wish to keep up with the progress now being made.

G. V. R. BORN

THE LEUKÆMIC CELL

The Cytology and Cytochemistry of Acute Leukæmias

A Study of 140 Cases. By G. F. J. Hayhoe, Dennis Quaglino and Richard Doll. (Medical Research Council Special Report Series, No. 304.) Pp. ix+105+74 plates. (London: H.M. Stationery Office, 1964.) 63*s*. net.

FOR nearly seventy years hæmatologists have largely relied on stains of the Romanowsky type (complexes of methylene blue derivatives with eosin) to differentiate between the types of normal and abnormal cells of the blood and blood-forming organs. Their most difficult task has been to distinguish between the cells of different acute leukæmias, and in this field the most experienced observers occasionally differ. To anyone who attempts this feat only occasionally, the marvel is that disagreement is not commoner, and that hæmatological diagnosis so often corresponds with clinical observation.

In this clearly written, well produced and illustrated book, a variety of cytochemical methods of examining the cells of the blood and bone marrow in acute leukæmia have been evaluated, by comparison with each other and with a Romanowsky stain. Some, like the peroxidase test, have been available for many years. Others have been introduced more recently, and their practical value has still to be established. Previous experience with these methods has added a few criteria useful in blood cell diagnosis, but most hæmatologists have not felt that any one of them has made their task more than marginally easier. In *The Cytology and Cytochemistry of Acute Leukæmias* all the most important methods available (new or not-so-new) have been tested on an adequate sample of cases, and the results, though not claimed as revolutionary, will probably convert many former doubters to the view that a battery of tests is likely to give substantial help in cases where one, or perhaps two, have left the nature of the condition uncertain.

Blood and bone marrow smears from 140 consecutive cases of acute leukæmia were investigated by Romanowsky and sudan-black staining, a peroxidase reaction, an azo-dye method for alkaline phosphatase, and the periodic acid–Schiff reaction. Salient characteristics observed by each method were recorded, semiquantitatively whenever possible, and analysed statistically with the aid of a computer. The result directed attention to eleven discriminating characters, on the basis of which it was possible to separate the cases into four groups. Initial consideration of Romanowsky characters alone had left fifty cases unclassified, but analysis of the results of all the tests together reduced this number to fifteen. The relation of the four groups to the conventional classification was next considered, and it became clear that they corresponded to lymphoblastic, myeloblastic, monocytic or myelomonocytic, and erythræmic myelosis types, respectively.

The first group (lymphoblastic) was found to differ, with regard both to cytological and to general biological characters, from the other three, and the authors make the significant deduction that acute lymphoblastic leukæmia is a disease separate from the other types, but that the latter form a related group. They suppose that in the normal person there is one stem cell which can produce lymphocytes only, and another which produces myelocytes, monocytes, or erythrocytes, in response to appropriate stimuli.

Several other observations of interest are discussed. In Romanowsky preparations a few, apparently normal, mature cells are commonly seen in acute leukæmic blood, which are useful in distinguishing the types of the disease. Further, in these preparations, primitive cells often appear similar to corresponding precursor cells in the normal bone marrow. The authors have been able to show that both these appearances are misleading. Cytochemical methods (notably the sudan-black, peroxidase, and periodic acid–Schiff stains) show that both the apparently mature cells and the apparently primitive cells in leukæmic blood differ from their presumptive counterparts in normal blood or bone marrow.

Finally, a hypothesis about the nature of the essential cellular lesion in acute leukæmia is put forward, namely, that there is failure of the proliferative capacity of cells at an early stage of differentiation, with the result that cytoplasmic materials (sudanophilic and periodic acid–Schiff positive), which are present in mature normal cells, accumulate in leukæmic cells without corresponding nuclear development. By analogy with what is known of the megaloblasts of Addisonian anæmia, it is postulated that this failure is due to a prolongation of interphase at the second resting period ("G_2" of Lajtha and Oliver[1]) with consequent asynchrony of nuclear and cytoplasmic developments.

As a student of viral-induced leukæmia in animals (which may or may not be analogous to the human disease) I value this survey of modern hæmatological methods highly. Several murine leukæmogenic viruses induce either lymphoid or myeloid leukæmia under different conditions, while others induce a blood disease in which abnormal cells of all the hæmopoietic series may appear. Clearly, the methods so carefully tested by the authors may help in the analysis of this complex situation, and perhaps give an indication of the point of attack of these viruses. To clinical hæmatologists the book will be stimulating, and valuable as a book of reference for some years to come. They will be grateful to the authors for what must have been a laborious task, and for the factual and restrained manner in which the results have been presented.

M. H. Salaman

THE LOWER ORDERS

The Lower Metazoa

Comparative Biology and Phylogeny. Edited by Ellsworth C. Dougherty. Pp. xi + 478. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1963.) 140*s*.

CIRCUMSTANCES prevented the prompt publication by the Kaiser Foundation of the *Proceedings* of their second annual symposium on "Comparative Biology" (1960). Most of the papers, along with some new matter, have now been independently published in *The Lower Metazoa*. The papers collected are inevitably heterogeneous, but the volume is mainly concerned with views about the relationships of the lower animal phyla with each other and with the Protozoa. Only one paper (by D. D. Jensen) looks upward to the vertebrates and derives them, via myxinoids, from the hoplonemertines.

For many lower Metazoa (here taken as extending up to and including the Aschelminthes) there is little or no fossil record. Phylogeny therefore relies heavily on the notions of homology and convergence. There is much room for speculation and speculation readily expands to fill the room available. Remane's criteria of homology are discussed in some detail by Hanson, and Remane himself claims that "morphology can be defined as the search for homologies". The open-minded reader of this book will find that one man's homology is another man's convergence and that there is much dispute over what is primitive and what degenerate. Nevertheless, the book is stimulating, provocative and in places exciting, except perhaps to the purist rigorously analysing his authenticated data. An index would have been useful.

The book opens with 21 papers on comparative morphology and phylogeny, and although it is impracticable to summarize them adequately, some idea of the main positions taken may be given. The earliest metazoan was probably an acoele (Hanson; Steinböck) deriving from some gymnostomatous ciliate (Hanson); or was a planuloid deriving from flagellates (Remane, Hand); or was a sponge deriving from the higher volvocines (Tuzet). As to the cœlom, the enterocœlic origin is best founded (Remane), or the mode of formation cannot yet be decided (Hartman), or it may have been differently evolved in different phyla with much convergence (Clark).

In the cœlenterates are two main branches showing radial symmetry: Hydrozoa and Scyphozoa; the bilateral Anthozoa are an offshoot from the latter (Uchida) and the sub-phylum Ctenophora from the former (Komai). The Turbellaria show trends in their organ systems (Karling) enabling the hypothetical archetype to be both described and illustrated: compared with it, the Acoela are not so primitive! (Ax). Turbellaria arose by progressive neoteny from a parenchymula-like larva of the Cnidaria, and the latter from flagellates (Beklemishev).

Rotifers are closely linked with gastrotrichs (Lang; Ruttner-Kolisko) or are not (Remane): they may have as ancestor a primitive annelid like the Dinophilidae (Ruttner-Kolisko). The ancestral nematode can be described in some detail (Maggenti); free-living Phasmidia living in terrestrial saprobiotic substrates are pre-adapted to parasitism, which is polyphyletic in nematodes (Osche).

There are six papers under comparative physiology. Baldwin postulates that, given the common metabolic ground-plan essential to the survival of animals, possible adaptations are severely restricted and evolution is slow. Dougherty outlines the present position of nutrient media for axenic organisms. G. O. Mackie discusses the nature of individuality in the Siphonophoran bud-colonies, which have reached the organ grade of construction by converting whole individuals into organs. E. J. Martin describes a toxin in the cœlenterate *Rhodactis howesii*. Jennings discusses nutrition in the carnivorous Turbellaria and Rhynchocoela and in the parasitic Trematoda, in which nutritional adaptations are physiological. D. Schneider has investigated phototropism in the bryozoan *Bugula* in which growth is purely apical.

Under other disciplines are seven papers, including C. Lévi on gastrulation in sponges, and Nicholas and Hynes on the embryology and development of *Polymorphus minutus*. Embryology shows a distorted form of spiral cleavage with no clear homologue of the 4*D* cell and no clearly defined entoderm or mesoderm. M. Benazzi describes the chromosome cycle in polyploid biotypes of triclads, and J. H. Phillips presents preliminary evidence for immune mechanisms in cœlenterates. R. W. Pennak considers that the successful invasion of a freshwater habitat from the sea is an evolutionary rarity, more likely to occur via the sandy beach 'psammolittoral' and ground-water 'phreatic' than directly by the estuarine waters route. M. Voge remarks on the profusion of (moist) habitats invaded by flatworms and on their symbiotic relationships. Finally, R. B. Brunson presents some anomalous results in culturing gastrotrichs.

B. G. Peters

Science

Method and Meaning. Edited by Samuel Rapport and Helen Wright. (The New York University Library of Science.) Pp. xii+258. (New York: New York University Press, 1963.) 4.95 dollars.

THIS book, *Science: Method and Meaning*, presents a selection of excerpts from the writings of scientists, dealing first with science and the scientist and, in the second part, with science and its place in the modern world. Those in the first part are chosen to illustrate the nature of scientific activity, the stages of observation, hypothesis and experiment, and the process of discovery. They include a classic statement by T. H. Huxley on the method of scientific investigation and Warren Weaver's discussion of the imperfections or limitations of science. Dr. J. B. Conant's account of the overthrow of the phlogiston theory is also included, as well as passages from the writings of Claud Bernard from J. Livingston Lowe's *The Road to Xanadu*, from W. I. B. Beveridge's *The Art of Scientific Investigation* and from J. R. Baker's *The Scientific Life*. The excerpts in the second part are taken from A. N. Whitehead's *Science in the Modern World* and from the writings of Harlow Shapley, E. W. Sinnott, J. Bronowski, G. T. Seaborg and W. K. Heisenberg.

While the selections have obviously been made with some care, and are fully representative of the varied aspects of scientific activity and its impact on the world, the basis of selection is not clear and the general effect is rather that of patchwork. The book lacks the unity of Sir Richard Gregory's *Discovery*, Prof. W. I. B. Beveridge's *The Art of Scientific Investigation*, or J. R. Baker's *The Scientific Life*, for example, to mention only three which cover essentially the same ground and probably achieve the same objective more effectively. The scope of the book is perhaps slightly wider, however, and it could well serve as an introduction to a somewhat more extensive field of reading. Here it is unfortunate that the references to sources are lacking in precision: readers unfamiliar with the books quoted may have difficulty in locating the originals and there is a slip in the title of Whitehead's book. There is, however, much of merit in the book, but as a whole it does not measure up to the opportunity which the editors have seen but scarcely grasped.

R. BRIGHTMAN

Fundamentals of Palæontology

Reference work for Palæontologists and Geologists of the U.S.S.R. Vol. 15: Gymnosperms and Angiosperms. Edited by A. L. Takhtajan, V. A. Vachrameev and G. P. Radczenko. Pp. 742+80 plates. (U.S.S.R.: Academy of Sciences, Moscow, 1963.) n.p.

THIS impressive book is the final volume of the *Osnovii* series (which covers the whole field of palæontology), and is the second of the two volumes devoted to fossil plants. The earlier palæobotanical volume (*Nature*, 201, 652; 1964) dealt with the lower groups, while the present work covers the seed plants. The general style of treatment, the format and type of illustration are very much the same as in the earlier volume, and most of Harris's comments are equally applicable here. Like the earlier work, there are a considerable number of contributors in addition to the three editors.

To a reader outside the U.S.S.R., the extensive treatment given to the Angiosperms is perhaps the most noteworthy feature of the volume; almost exactly half the work is devoted to them. This is an unusually large fraction compared with other palæobotanical texts, and reflects the interest and considerable contribution made in this field of palæobotany by Prof. Takhtajan. Seward, in his four-volume work on fossil plants (now in many respects out of date, but still probably the nearest equivalent in English to the palæobotanical volumes of the *Osnovii*), significantly never included the Angiosperms, although he dealt with all other groups.

The introductory section of that half of the volume dealing with Angiosperms is particularly useful to the palæobotanist in treating those aspects of the living members of the group which are important to him, but which can only be found rather widely scattered in purely botanical literature; these are, particularly, wood anatomy, leaf form, pollen morphology and fruit structure. The consideration given in the whole volume to fossil pollen is especially salutary, as many Western palæobotanists working on pre-Quaternary material are apt to regard palynology as a branch of stratigraphy rather than an integral part of the general study of fossil plants. The acceptance of the identity of living Gymnosperm genera in the Mesozoic on the basis of their pollen alone (for example, Russian Jurassic *Podocarpus*) may seem an over-optimistic reliance on the systemic value of pollen characters. But the attempt at integrating data from dispersed spores and macrofossils is at least refreshing.

W. G. CHALONER

Nuclear Physics

Edited by V. F. Weisskopf. (Italian Physical Society. Proceedings of the International School of Physics "Enrico Fermi", Course 23, Varenna on Lake Como, August 7–August 26, 1961.) Pp. v+186. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1963.) 60*s*.

THE *Proceedings* of the Varenna Schools used to be published as supplements to *Il Nuovo Cimento*. They now appear in hard covers from the Academic Press, but the style, down to the last details of typography and the familiar group photograph, remains unchanged. Only the density of misprints seems to have increased; it is here regrettably high.

Three courses take up most of the book; Villars on the Hartree–Fock approximation in nuclear physics, Levinson on nuclear physics (deformed orbitals in shell-model theory) and Brown on collective motion and many-body techniques. The other two courses, de-Shalit on nuclear moments and Ericson on the compound nucleus and random phase approximation ('fluctuations'), are rather shorter.

Much of this is good teaching, with at least some of the hand-waving that (in moderation) is an essential part of good teaching coming through. The resulting informality makes for refreshing reading and provides a good introduction to many of the subjects covered as well as useful insights to those more familiar with them.

Of perhaps more doubtful value is the inclusion of four seminars on special topics. These are doubtless intended to be concrete examples of research related to the topics of the courses, but their teaching value in this role is limited and I feel these contributions would sit less awkwardly as research papers in the journal literature. If their exclusion had made possible a modest reduction in the price, so much the better for everybody.

J. M. SOPER

Analysis of Petroleum for Trace Elements

By O. I. Milner. (International Series of Monographs on Analytical Chemistry, Vol. 14.) Pp. viii + 128. (Oxford, London, New York and Paris: Pergamon Press, 1963.) 35*s*.

THIS is a very useful monograph. It is very well referenced, and, for each of the elements which have most frequently to be determined, the author gives a recommended method of analysis the suitability of which has been confirmed by his personal experience. The title refers only to the analysis of petroleum, but the determination of trace elements in catalysts is also covered.

The book provides a very convenient and useful collection of many modern references to methods for the determination of trace elements in the petroleum industry. For those who are inexperienced in this field, the recommended methods should be extremely valuable, but they should not be new, except perhaps in detail, to the experienced petroleum analyst.

Chapter 1, "Introduction", provides information on the necessity for trace analysis, and the first half of Chapter 2 (28 pp.), on "Principles and Practices", is devoted to matters of interest to all trace analysts, for example, sampling, contamination, reagent purity, storage of solutions, and blank determinations. The remainder of the chapter deals with decomposition techniques, separations and finishing techniques. The following eleven chapters, at an average of six pages each, deal with the determination of arsenic, chlorine and bromine, copper, iron, lead, nickel, nitrogen, phosphorus, sodium and potassium, sulphur and vanadium. The reason for the presence and the analysis of each element is discussed and applicable methods are reviewed and well referenced. The author gives his recommended method for each element and all the methods are based on chemical procedures with the intention that they can be carried out by laboratories which are only modestly equipped. Some instrumentation is necessary, of course, in the form of spectrophotometers, flame photometers, etc.

In these chapters it is perhaps a little surprising to find the author, aware of the usefulness of benzene and xylene sulphonic acids, recommending the ashing of petroleum materials with sulphuric acid for the determination of iron, nickel and vanadium. All the recommended procedures quoted are complete in themselves, apart from that for sulphur, which requires reference to another publication.

The final chapter (19 pp.) reviews methods for determining eleven elements (barium, boron, calcium, cobalt, fluorine, magnesium, manganese, molybdenum, oxygen, silicon and zinc), which are less frequently determined in trace amounts, but no recommended procedures are given. The index, considering the size of the book, is adequate.

E. THORNTON

Tsetse Flies in Northern Nigeria

A Handbook for Junior Control Staff. By Howell Davies. Pp. 211. (Zaria, N. Nigeria: Gaskiya Corporation, 1963.) 20*s*.

THIS book has been expressly written as a pocket instruction manual for African tsetse control staff, and as such is outstandingly good and a model of its kind; Howell Davies has clearly given a great deal of thought to how a large body of information can be simply and attractively presented to his junior African reader, not only in a way that is easily readable but also easily memorized.

Although primarily concerned with Northern Nigerian species, this book should commend itself to any layman wanting to get quickly to the facts about tsetse flies in general, for a wealth of information is given which is easily tapped by means of the excellent index. Each fact is given very clearly in concise numbered paragraphs, and almost every aspect of tsetse flies is covered—including their recognition, bionomics, disease transmission, control and how to carry out tsetse surveys. The main text is augmented with useful glossaries giving the local Hausa names of trees and animals often associated with tsetse in their natural environment, and simple drawings help the reader to picture things not easily described in words. Sketches of the spoor of large game animals are included, perhaps rather optimistically in face of the extreme rarity of such animals as elephant and giraffe in Northern Nigeria. Altogether an admirable little book, but, unfortunately, very poorly bound.

R. W. CROSSKEY

Physiologie, Comportement et Écologie des Acridiens en Rapport avec la Phase.

(Colloques Internationaux du Centre National de la Recherche Scientifique, No. 114, Paris, 9–13 Avril, 1962.) Pp. 342. (Paris: Éditions du Centre National de la Recherche Scientifique, 1962.) n.p.

THIS volume presents the proceedings of the five-day colloquium on the physiology, behaviour and ecology of locusts in relation to phase held in Paris during April 1962. Eighteen speakers from widely scattered countries gave papers on a wide variety of topics within these three aspects of locust biology. M. J. Norris, M. Papillon, M. Verdier, P. Joly, J. de Wilde (and G. B. Staal) and K. C. Highnam spoke on physiology, P. E. Ellis, P. T. Haskell and C. E. E. Rungs on behaviour, and R. C. Rainey, Z. Waloff, E. M. Shumakov, P. E. Kohler and H. A. F. Lea on ecology; M. L. Roonwal, J. S. Kennedy, R. E. Blackith and F. O. Albrecht spoke on more general topics within the subject of the colloquium. The colloquium was convened by F. O. Albrecht, under the presidency of Sir Boris Uvarov.

The papers are published in the language of their delivery, with French and English summaries, except for two which appear in two languages. The discussions are entirely in French, having been translated where necessary. The colloquium has served an invaluable purpose in bringing together a large number of important papers on topics within its broad subject, and this volume will be not only of great value to all those engaged in locust research, but also useful to workers on the physiology, behaviour and ecology of insects generally.

D. R. RAGGE

Méthodes Statistiques à l'Usage des Médecins et des Biologistes

Par Daniel Schwartz. Pp. 290. (Paris: Éditions Médicales Flammarion, 1963.) 60 francs.

SEVERAL books on medical applications of statistical methods have appeared recently in languages other than English, and Dr. Schwartz's book is an elegant addition to their number. The author's treatment of basic statistical methodology is rather fuller than that in Bradford Hill's *Principles of Medical Statistics*, and includes brief descriptions of one- and two-way analysis of variance and of multiple correlation. Examples are drawn from clinical and laboratory research, but there is no discussion of vital statistics or of the problems of data collection and processing. The exposition is non-mathematical and the basic concepts are carefully explained. The book as a whole has a slightly academic flavour, but this may be because the author has deliberately restricted its scope. Discussions of clinical trials, ætiological investigations, biological assays and other topics are promised for further volumes.

P. ARMITAGE

La Chromatographie

Par Prof. L. Savidan. 2e Edition. (Monographies Dunod.) Pp. x+115. (Paris: Dunod, 1963.) 9.60 francs.

THIS extremely brief volume gives, in French, an account of all aspects of chromatography at the lowest possible level. The brevity of the treatment may be judged from the fact that the numerous techniques of paper and film chromatography are dealt with in eleven pages and the whole of gas chromatography in twenty more. The material is clearly presented but is in most instances rather dated. The only gas chromatographic apparatus illustrated, for example, dates from 1953. As an introduction to the subject the book would prove useful, although students in Britain would find considerably better value in the several introductory books available in English.

J. H. PURNELL

STRUCTURE OF HÆMOGLOBIN

AN X-RAY EXAMINATION OF REDUCED HORSE HÆMOGLOBIN

By DR. M. F. PERUTZ, C.B.E., F.R.S., DR. W. BOLTON, DR. R. DIAMOND, DR. HILARY MUIRHEAD and DR. H. C. WATSON

Medical Research Council Laboratory of Molecular Biology, Hill's Road, Cambridge

THIS article is a sequel to Muirhead and Perutz's recent X-ray investigation of reduced human hæmoglobin[1]. The structure of this form was found to differ from that of horse oxyhæmoglobin[2] in the arrangement of the two β-chains. It was left uncertain, however, whether this was a rearrangement accompanying the oxygenation reaction or whether it merely represented a structural difference between the hæmoglobins of man and horse. X-ray analysis of a newly discovered crystal form of reduced horse hæmoglobin has now removed this uncertainty.

One easily measurable parameter distinguishing human reduced from horse oxyhæmoglobin is the distance between two mercury atoms attached to the reactive cysteyl residues of the β-chains. We found this to be 37·3 Å in reduced horse hæmoglobin, in agreement with the value of 37·7 Å in the human reduced form[1] and different from that of 30·0 Å in horse oxyhæmoglobin[2]. Taken together with electron-density projections on a plane normal to the molecular symmetry axis, this result indicates that the reduced hæmoglobins of man and horse have very similar structures, and that the rearrangement of the β-chains must be due to the oxygenation reaction.

On gradual exposure of the reduced crystals to air, certain lattice changes occur, indicative of an ordered transition to the oxyhæmoglobin structure. Crystallization of a mixture of reduced and oxyhæmoglobin leads to the appearance of two different crystal forms, one having the morphology and absorption spectrum of the oxygenated, and another having the morphology and absorption spectrum of the reduced form.

Experimental

Earlier crops of reduced horse hæmoglobin, precipitated from salt-free solution, crystallized in the space group $C3_12$ and had the unit cell dimensions $a = 56{\cdot}1$ and $c = 354$ Å; the great length of the c axis made them unsuitable for X-ray analysis[3]. The present crystals were grown in a 2·5 M mixture of K_2HPO_4 and NaH_2PO_4 solution at pH 6·4, in the presence of 10^{-2} M ferrous citrate, and were mounted wet in thin-walled glass capillaries, in an atmosphere of nitrogen. The crystals are orthorhombic, and form bipyramidal prisms elongated along [001], with faces {110} and {111}. Birefringence and dichroism are weak, with the direction of least optical absorption parallel to [001]. The unit cell dimensions of the wet crystals are $a = 77{\cdot}0$ Å, $b = 81{\cdot}8$ Å and $c = 92{\cdot}7$ Å; $V = 584{,}000$ Å^3; $n = 4$. The space group is $C222_1$, which has eight general positions. The four molecules in the unit cell thus have to lie on dyad symmetry axes (Figs. 1 and 5).

Crystals of reduced horse hæmoglobin in which the two reactive sulphydryl groups had been blocked with mercuribenzoate were found to be isomorphous with the parent compound, but gave diffraction patterns with markedly different intensities. The diffraction patterns of the three principal zones of mercuribenzoate and native hæmoglobin were recorded on 9° precession photographs, extending to a spacing of 5·5 Å^{-1}. Intensities were measured with a Joyce Loebl microdensitometer. They were then corrected by the usual factors, and put on an absolute scale by comparison with horse oxyhæmoglobin[4].

Locating the Mercury Atoms

The squares of the differences in structure amplitude between mercuribenzoate and native hæmoglobin were used to calculate difference Pattersons in projection on the three principal planes (Fig. 2). The unit cell contains eight mercury atoms, one per asymmetric unit. The asymmetric unit of the corresponding three-dimensional Patterson can be shown to contain six vector peaks of equal weight which all lie in Harker sections (Fig. 3). In projection on the three principal planes these peaks, and their symmetrically related counterparts, would produce a system of single- and double-weight peaks, as shown in Fig. 4. Seen in projection on (100), for example, peak 1 at $x = 0$ and peak 3 at $x = \frac{1}{2}$ have single weight, whereas peaks 2, 4, 5 and 6, which have their counterparts generated by reflexion across (100), have double weight.

The three observed projections show the expected distribution of double-weight peaks. The single weight peaks also appear in the expected positions, but their weight is significantly above background only in the projection on (010). Fortunately, the three-dimensional vector structure can be constructed from the distribution of the double-weight peaks alone, and gives the mercury parameters as $x = 0{\cdot}0930$, $y = 0{\cdot}145$, $z = 0{\cdot}155$, and symmetry-related positions. After refinement by R. G. Hart's method[5], these changed slightly to $x = 0{\cdot}0947$, $y = 0{\cdot}146$, $z = 0{\cdot}155$. The positions of the mercury atoms are illustrated in Fig. 5.

Excluding reflexions too weak to be observed, the reliability factors:

$$R = \frac{\Sigma\Sigma\,(\,|\,\Delta F_{\text{obs}}\,|\,-\,|\,\Delta F_{\text{calc}}\,|\,)}{\Sigma\Sigma\,|\,\Delta F_{\text{obs}}\,|}$$

were found to be 0·280 for $\Delta F(hk0)$, 0·276 for $\Delta F(h0l)$ and 0·298 for $\Delta F(0kl)$. In X-ray analyses of small molecular structures these factors would be considered at least twice as large as they ought to be, but it must be remembered that we are here dealing with differences between

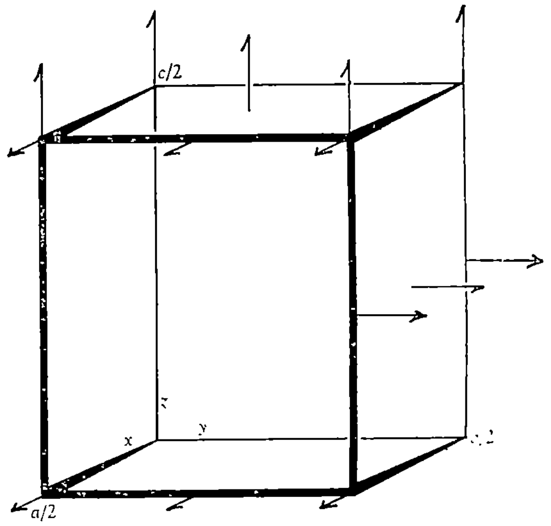

Fig. 1. Arrangement of symmetry elements in the space group $C222_1$ → dyad ⇀ screw dyad

two isomorphous compounds where experimental errors are much larger. In fact, the foregoing values are as low as any obtained in previous analyses of proteins[2,6].

Orientation of the Molecules

The four hæmoglobin molecules in the unit cell may be placed in two alternative ways, either on the dyads parallel to *a* or on those parallel to *b* (Fig. 1). In the first case, peak 1 in Fig. 2*a*, and in the second case, peak 4 in Fig. 2*b*, would represent a vector between two mercury atoms attached to the same hæmoglobin molecule. Peak 1 corresponds to a mercury–mercury distance of 37·3 Å, in good agreement with that of 37·7 Å found in human reduced hæmoglobin. Peak 4 would correspond to a distance of 23 Å which has not been found in any form of hæmoglobin so far. Thus, the mercury positions indicate the arrangement of the β-chains in reduced hæmoglobin of horse to be the same as in the human form.

Ideally this should be tested by an X-ray analysis in three dimensions, but this is very laborious, and it was thought that a two-dimensional analysis might suffice provided that the molecule could be recognized in projection along its dyad axis. Surrounding each dyad, a hole passes right through the molecule and shows up as a central flat region in projection. The dimensions of this flat region are such that it forms an easily recognizable feature (Fig. 13, ref. 2).

Isomorphous substitution with mercuribenzoate was used to calculate the signs of 57 out of 85 observable *h*0*l* and of 58 out of 81 observable 0*kl* reflexions. Fourier projections on (100) and (010) were then calculated (Fig. 6). A flat central region, corresponding to the hole, is shown by the projection on (100), but not by that on (010). Hence the molecular dyads are parallel to *a*, as expected, and 37·3 Å represents the distance between pairs of mercury atoms attached to the same molecule.

So as to see if the size of the flat region fits the hole in reduced, rather than in oxyhæmoglobin, the projected electron density of models of each of the two forms was calculated. In the case of oxyhæmoglobin, all that was needed was to sum the known three-dimensional density[2] along the lines of constant *x* and *z*. The density of the reduced model was obtained by first summing the densities

Progress in Nucleic Acid Research and Molecular Biology

Edited by J. N. DAVIDSON, The University, Glasgow, Scotland

and WALDO E. COHN, Oak Ridge National Laboratory, Oak Ridge, Tennessee

Formerly: Progress in Nucleic Acid Research

This modification in title has been adopted to reflect the broad scope of research actually presented in this series.
Volume 3 embodies the latest developments in the field of nucleic acid research and molecular biology. Much more than a review, it is a medium for the exposition of new research, theories, techniques, and controversial material.
Future volumes will carry this theme forward, integrating information from experimental work in various disciplines and providing timely perspectives on the properties and roles of biologically important macromolecules.

Volume 3, October 1964, about 350 pp., approx. $11.00; 88s.

K. S. Kirby: Isolation and Fractionation of Nucleic Acids.
David M. Prescott: Cellular Sites of RNA Synthesis.

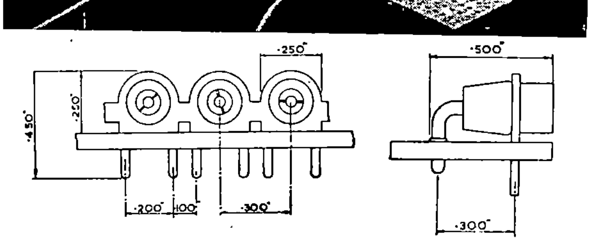
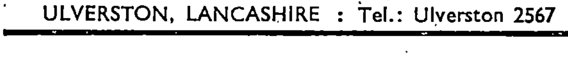
OXLEY

PRINTED CIRCUIT SOCKETS

The OXLEY printed circuit sockets are designed for direct mounting on ·1" module printed circuit board with standard ·050" minimum diameter holes, and accepts our standard plug Type 50P/156.
The mounting is arranged so that the plugs may be inserted in a plane parallel to the printed circuit board thus permitting close stacking of circuit boards.
Sockets can be supplied from 1 to 12 ways, colours can be in black, brown, red, orange, yellow, green, blue, violet, pink, grey or white.





Write for technical details of these or any other Oxley products

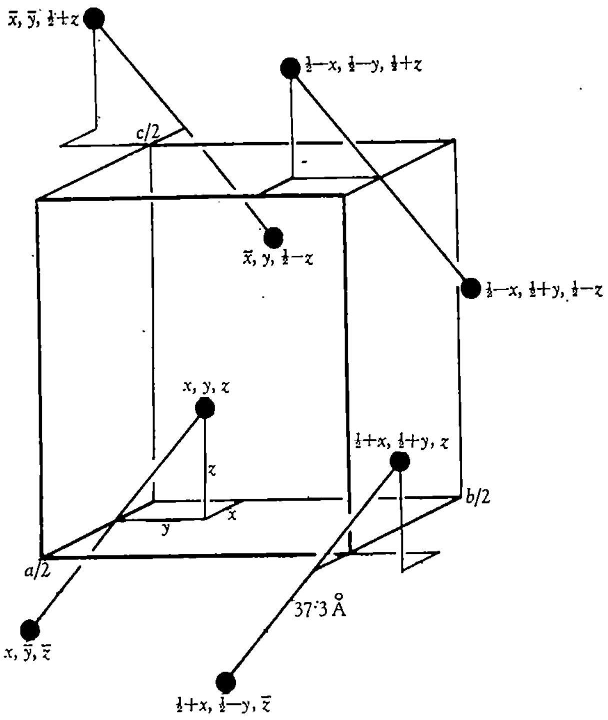

Fig. 5. Arrangement of mercury atoms deduced from Figs. 1–4. Mercury atoms attached to the same hæmoglobin molecule are connected by lines

of the α- and β-chains of oxyhæmoglobin separately; the β-chains were then shifted in opposite directions, as indicated by the structure of human reduced hæmoglobin (Fig. 10*b*, ref. 1), and their densities added to those of the α-chains.

The projected views of the two models are seen in Fig. 7. Superposition of Fig. 6*a* (horse reduced) shows that the observed flat region surrounding the dyad axis fits the hole in human reduced (Fig. 7*b*), but is too big for the hole in the horse oxy form (Fig. 7*a*). The lack of exact agreement between the calculated and observed projections of reduced hæmoglobin may be accounted for in part by the omission of 23 out of the 81 terms of the Fourier summation, and possibly also in part by slight changes in the tilt of the sub-units accompanying the shift of the β-chains.

Structural Transformations in Single Crystals

When crystals of reduced hæmoglobin are exposed to air, they generally crack up and lose most of their X-ray diffraction pattern. When the present crystals were left to become oxygenated, or oxidized, very slowly over a period of several weeks, characteristic and well-ordered lattice changes occurred. At first, extra reflexions appeared at $h + k = 2n + 1$, indicating a change from the *c*-face centred to a primitive lattice. These extra reflexions were weak and confined to spacings smaller than 10 Å^{-1}. The cell dimensions remained unchanged, except for a shrinkage of *b* from 81·8 to 79·6 Å. On further exposure to air, *b* was reduced to 76·0 Å, again without any significant change in *a* or *c*, and the lattice reverted to the *c*-face-centred form. We found that the first step of these lattice changes could be reversed by the addition of ferrous citrate, and the original diffraction pattern restored, but we have not yet succeeded in reversing the second step without breaking the crystals.

Rigorous interpretation of the two transitions would require a determination of the mercury positions in each lattice, which has not yet been done. However, their meaning is fairly obvious. The gap separating the two β-chains is almost exactly normal to *b*. The narrowing of the gap on oxygenation, or on oxidation to methæmoglobin, therefore causes the crystals to shrink along *b* without affecting the other two lattice dimensions.

The additional reflexions which appear on X-ray photographs of partially oxygenated crystals are reminiscent of the superlattice lines seen on powder photographs of copper–gold, and other alloys, after annealing, and may have a similar interpretation. At high temperatures the copper and gold atoms in these alloys are distributed

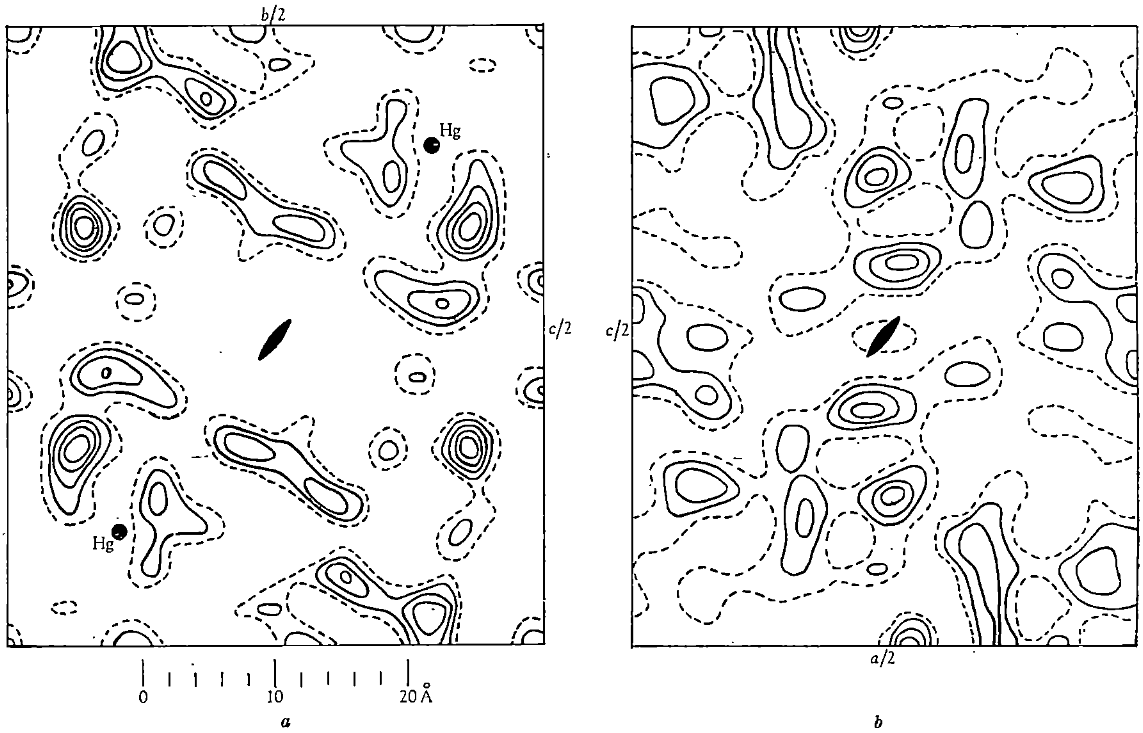

Fig. 6. Fourier projection of reduced horse hæmoglobin calculated from isomorphous replacement with mercuribenzoate: (*a*) on (100); (*b*) on (010)

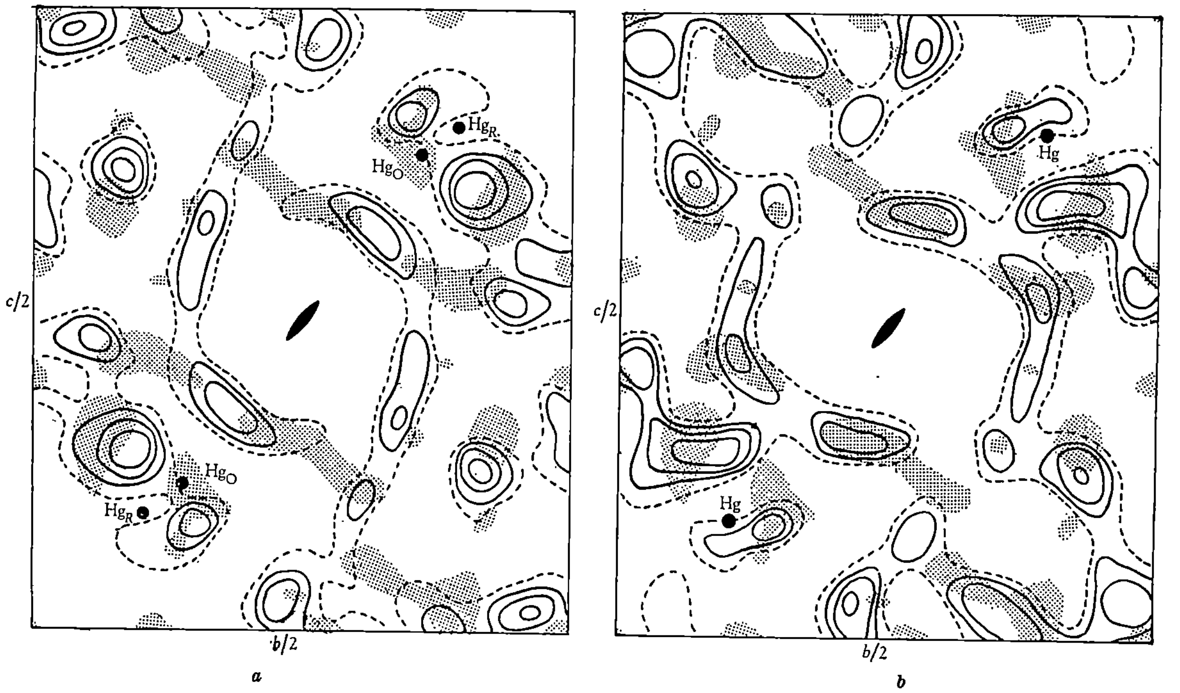

Fig. 7. Electron density projected on a plane normal to the molecular dyad axis calculated from: (*a*) the three-dimensional electron density distribution of horse oxyhæmoglobin (ref. 2); (*b*) the α- and β-chains of horse oxyhæmoglobin rearranged approximately as in the human reduced form. The shaded areas indicate the outlines of the peaks covered by the first full contour in Fig. 6*a*

at random in a cubic face-centred lattice. On annealing they segregate into specific sites, and the difference in scattering amplitude between the gold atoms at the corners and the copper atoms at the face-centres of the lattice gives rise to faint additional reflexions. In the present instance such reflexions could arise from an orderly arrangement of two kinds of hæmoglobin molecules, for example, one where oxyhæmoglobin occupied the dyads at $y = 0$ and reduced hæmoglobin those at $y = \frac{1}{2}$.

Crystallization of Mixtures of Reduced and Oxyhæmoglobin

Horse oxyhæmoglobin is less soluble than the reduced form, so that when a mixture of the two forms is added to phosphate buffer, oxyhæmoglobin crystallizes out first, leaving reduced hæmoglobin behind in solution. Occasionally the reduced form also crystallizes out, resulting in a mixture of crystals: one kind with the morphology and absorption spectrum of oxyhæmoglobin and another with corresponding properties of the reduced form. Crystals showing mixed spectra, such as would be given by the 'superlattice' described here, were not seen in fresh preparations, although they were found in preparations which had been kept for several months.

Conclusions and Discussions

(1) The distance between the two mercury atoms attached to the reactive sulphydryl groups of reduced horse hæmoglobin is 37·3 Å, in agreement with the value of 37·7 Å found in the reduced human form, and different from the 30·0 Å found in horse and bovine oxyhæmoglobin[2,11]. The dimensions of the hole surrounding the dyad at the centre of the molecule are also in agreement with the former and different from the latter structure. This suggests that the reduced forms of human and horse hæmoglobin have very similar structures, which differ from oxyhæmoglobin in the arrangement of the β-chains. Hence the structural transformation accompanying the reaction of hæmoglobin with oxygen may now be considered as proved. Its wider implications have already been discussed by Muirhead and Perutz[1].

(2) It is often asked whether the structure of proteins in the crystal is the same as in solution; old, as well as recently, published evidence suggests that this question may be answered in the affirmative[7-10]. The present results show, not only that crystalline hæmoglobin reacts with oxygen, which was known, but that the structural transformation accompanying the reaction also takes place in the crystal. Clearly the interatomic forces shifting the β-chains are stronger than those acting between neighbouring molecules in the lattice.

(3) It is interesting to find reduced and oxyhæmoglobin crystallizing out separately from a mixture as though they were different phases. An intermediate form did appear on partial oxygenation of single crystals of reduced hæmoglobin, and we cannot be sure that it did not also precipitate from solution and remained unnoticed, but the X-ray pattern given by these crystals suggests that they contain an ordered arrangement of reduced hæmoglobin molecules on one set of sites, and of oxy- or met-hæmoglobin molecules on another set of sites, rather than a single molecular species of structure intermediate between the two forms.

The formation of such an ordered arrangement has the further implication that a reduced molecule, when compressed by deformation of the lattice, due to shrinkage of neighbouring oxygenated molecules, itself becomes more susceptible to oxygenation than those molecules which are not so stressed. If this were not the case, molecules would become oxygenated at random, rather than in the selective manner necessary to produce a superlattice.

A SURVEY OF THE SOUTH SANDWICH ISLANDS

By Dr. P. E. BAKER, Dr. M. W. HOLDGATE, Dr. R. E. LONGTON,
P. J. TILBROOK, J. F. TOMBLIN, R. W. VAUGHAN and
Lieut.-Commander C. J. C. WYNNE-EDWARDS

THE eleven volcanic islands of the South Sandwich group lie on an arc between latitudes 56° 18′ and 59° 28′ S. and longitudes 26° 14′ and 28° 11′ W. (Fig. 1). Although discovered by Cook in 1775 and visited by Bellingshausen in 1819, the Islands were not examined in detail until 1931 when R.R.S. *Discovery II* spent 21 days in making running surveys and notes on structure, volcanic activity and fauna. In more recent years brief visits, especially by R.R.S. *Shackleton*, R.R.S. *John Biscoe* and H.M.S. *Protector*[1], have indicated that the charting of the group still needs improvement while the knowledge of the geology and land biology of the Islands, on which boat landings are seldom possible, has remained very slight. The recent visit of H.M.S. *Protector* during March 5–26, 1964, was planned as a general survey and was the result of active co-operation between the Royal Navy and the British Antarctic Survey. Two geologists (Dr. P. E. Baker and Mr. J. F. Tomblin, Department of Geology, University of Oxford), one botanist (Dr. R. E. Longton, British Antarctic Survey), and three zoologists (Dr. M. W. Holdgate and Mr. P. J. Tilbrook of the British Antarctic Survey and Mr. R. W. Vaughan, Government biologist in South Georgia) made up the scientific team, while Lieut.-Commander C. J. C. Wynne-Edwards, R.N. (Hydrographic Department, Ministry of Defence), supervised a Survey programme. The two helicopters carried by H.M.S. *Protector* were used to land parties, and for aerial reconnaissance and photography, while the vessel herself carried out sounding runs. Meteorological records were kept aboard the ship throughout the period.

H.M.S. *Protector* left South Georgia on March 4, 1964, and arrived at Leskov Island, westernmost of the South Sandwich group, on March 5. The scientific and survey parties spent 4 hours ashore and vertical photographs were obtained. On March 6 a party consisting of Tilbrook (leader), Longton, and Tomblin together with a Royal Navy radio supervisor and a Royal Marine support party were established on Candlemas Island, where most of them remained until the end of the project, making a detailed geological and biological survey and carrying out a small glaciological programme. Candlemas Island was selected for intensive study because it appeared geologically the best exposed and biologically the most varied member of the island arc. H.M.S. *Protector* then sailed southwards along the island chain and, on March 8, commenced her detailed programme by landing the shipborne scientific party (Holdgate, Baker and Vaughan) together with the main Survey party, to spend three days on Bellingshausen Island in the Southern Thule group. Visits of shorter duration were paid to the other two islands of this group after which, on March 12, the ship began to work northwards landing parties on each island in turn. The Candlemas group was reached again on March 17, and Longton and Tomblin transferred to the shipborne party for visits to Vindication and Visokoi Islands. The remainder of the Candlemas party was embarked on March 22. During March 19–23, almost continuous fog greatly hampered operations, preventing landings on Zavodovski Island and reducing the utility of a visit paid to the submerged cone north-west of that island which was believed to be the source of pumice ejected in 1962[2]. In view of these conditions H.M.S. *Protector* sailed for South Georgia, where Tilbrook and Longton were landed on March 24. A brief return visit to Zavodovski Island on March 26 met with no better success and after lying offshore in thick fog all day, H.M.S. *Protector* sailed at dusk for Bouvetøya.

The work done in the South Sandwich Islands and summarized here will be published in full in *British Antarctic Survey Scientific Reports* and other journals in due course.

SURVEY

(C. J. C. W.-E.)

Persistently bad weather and the near impossibility of landing from boats have, over the years, prevented any detailed, shore-based, survey of the group. Past expeditions have landed only occasionally[1] and no observations for geographical position have been made from ashore. The only thorough examination of the Islands, by R.R.S. *Discovery II* in 1931[3], was entirely ship-based and suffers from the usual limitations of such surveys.

In March 1964, the islands were reconnoitred by helicopter during H.M.S. *Protector's* southward passage and the survey was commenced at Bellingshausen Island.

A main station was established at the summit, and 'Tellurometer' (micro-wave distance measurement system) observations made in conjunction with a second survey party, moved as necessary to other stations on Cook and Thule islands.

From Bellingshausen Island a traverse commenced northwards to terminate ten days later at Visokoi Island. This traverse by 'Tellurometer' distances and theodolite angles occupied 16 stations and covered a distance of 330 km. Stations were sited in recoverable positions where possible and marked with brass plates cemented into the rock and surmounted by cairns. When weather conditions allowed, aerial photography was carried out, the survey stations being previously marked by 20-ft.-long strips of fluorescent material. This technique was applicable particularly to Candlemas and Bellingshausen Islands, where minor triangulation schemes were established and a larger-scale survey conducted, to meet scientific requirements.

Almost continuous cloud severely restricted astronomical sightings. Brief clearances during the period allowed, however, for theodolite observations which included five azimuths, five sun shots and one curtailed set of star sights. These, linked with the traverse, should improve the existing geodesy of the islands. From the traverse alone, discrepancies of up to 5 km in relative island positions have been observed.

While the survey was in progress ashore, H.M.S. *Protector* carried out a series of sounding runs in the vicinity. As her movements were largely conditioned by the needs of the shore parties, the ship was not free to range widely; nevertheless, the general scarcity of soundings in the area gives added importance to all

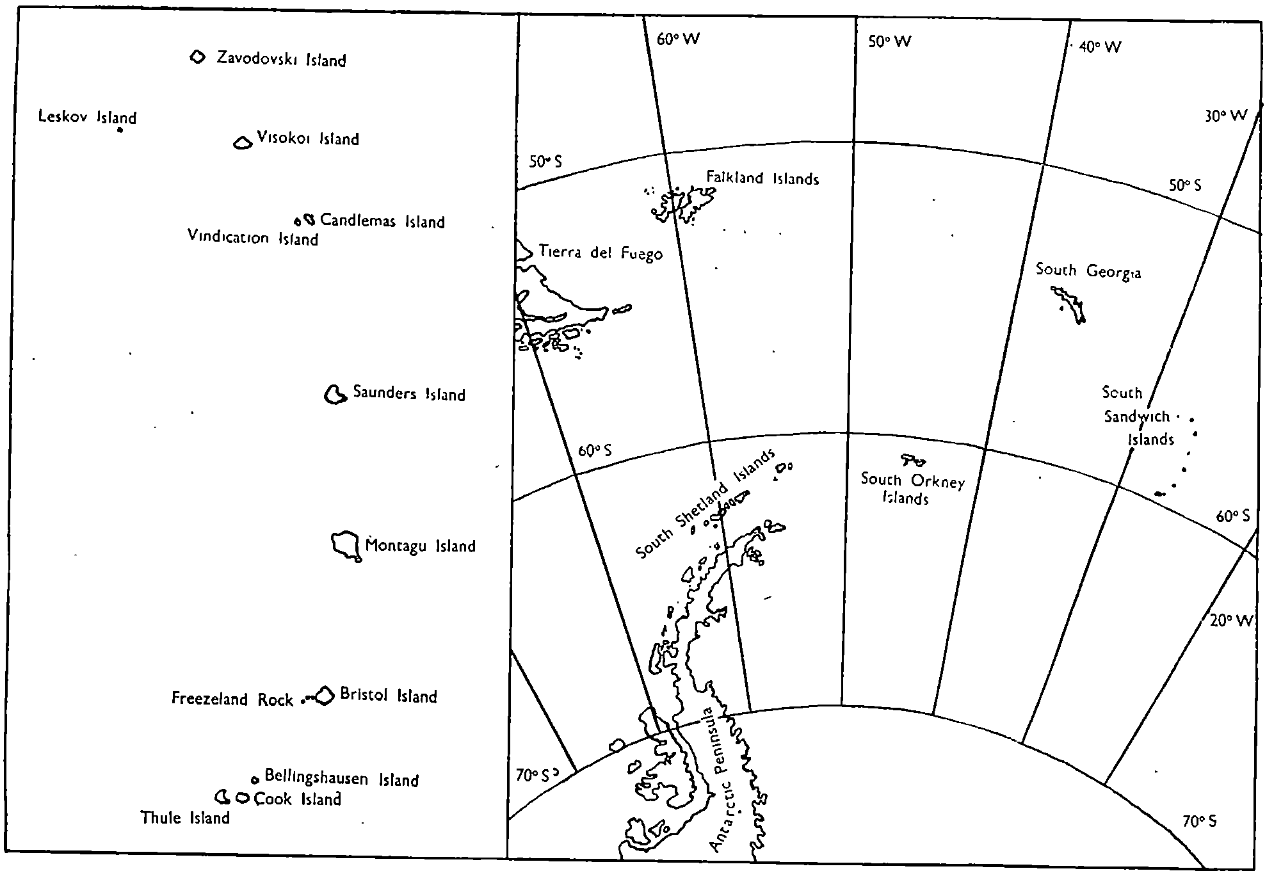

Fig. 1. The South Sandwich Islands (left) and their position in relation to South America, the Antarctic Peninsula, and the islands of the Scotia Ridge (right)

observations. H.M.S. *Protector* also obtained radar photographs to show island profiles; these will be used in conjunction with field observations and aerial photography to revise the existing topographic maps.

It is hoped to produce a revised chart of the Islands, together with large-scale maps of some islands, later in the year.

GEOLOGY

(P. E. B. and J. F. T.)

The northern part of Candlemas Island was selected for detailed geological study because of the diversity of recent volcanic features which are perfectly exposed in this relatively small area. Tomblin spent eleven working days on Candlemas, producing a geological map of the northern part on the scale of 400 ft. to the inch and making sketch maps of the accessible areas of the southern part of the island.

In the north of Candlemas, a scoria cone, rising to 760 ft. above sea-level, is surrounded by lava flows which have issued from its outer flanks and from a breached conelet to the south-west. The flows are commonly 50–150 ft. thick and form broad fans extending up to half a mile into the sea. Older flows are mantled by ash-fall deposits up to 2½ ft. thick. Younger lava surfaces are of *aa* type, with no ash cover. All lavas are basaltic-looking and those of the northern centre contain notably few phenocrysts. Present activity is concentrated in a vigorous fumarolic area occupying the whole of the western slopes of the cone, below which a steaming lake at sea-level contains water at up to 51° C. Steam issuing from the youngest lava flow suggests that this is not more than a decade or two old.

In addition to the detailed geological survey of Candlemas, geological sketch maps and extensive collections were made on Bellingshausen, Vindication and Leskov Islands. Investigations on Saunders, Montagu and Visokoi were restricted to a few small areas chosen for their good geological exposure in an otherwise ice-covered terrain. Only a few specimens were obtained from the heavily ice-capped Islands of Cook and Bristol, and a brief but informative examination was made of Freezeland Rock situated off the latter.

A variety of volcanic structures are displayed within the island group. Bellingshausen is a small youthful volcanic cone built of lavas and pyroclastics, and Leskov is evidently the relic of another small cone. Of the larger volcanoes, the most striking is on Saunders which is dominated by the 3,250-ft. ice-covered cone of Mt. Michael; vapour was billowing from its summit during the short time it was under observation. Three coalescing secondary centres form a prominent range of hills in the south-eastern part of Saunders Island. Visokoi has evidently been built about a single major volcanic centre, but several centres have probably contributed to the construction of both Bristol and Montagu Islands. Small parasitic cones were observed on Visokoi and Montagu, and the conspicuous conical hills seen on the eastern side of both Bristol and Montagu may be lateral volcanic domes.

Fumarolic activity was observed on each of the principal islands except Vindication, Montagu, Cook and Thule. The active crater at the summit of Thule reported by Holdgate[1] was not seen owing to poor visibility. Confirmation that several active fumaroles occur along the summit ridge of Leskov is of particular interest as their existence has been in doubt since Filchner's voyage in 1911[8]. Recent volcanic eruptions have been reported on

Bristol Island in 1956[4] and on Candlemas during 1953–54[1]. It is probable that a recent eruption has occurred on Saunders Island, where loose cinders are patchily distributed over the surface of the ice as on Bristol. A brief visit to the shoal believed to be the site of the 1962 submarine eruption 35 miles north-west of Zavodovski[1] revealed no significant change in the depth of 15 fathoms recorded in 1963[2]. Small samples of pumice were dredged from about 20 fathoms on the shoal and larger lumps of a similar pumice were afterwards discovered on the western coast of Bouvetøya, about 1,100 miles east of their supposed place of origin.

In contrast with rocks from the Lesser Antilles, the only other island-arc within the Atlantic basin, those of the South Sandwich Islands are in general more basaltic and less porphyritic. Only on Leskov, which lies to the west of the main arc, do andesitic types appear to predominate. Lavas with large pyroxene and olivine phenocrysts, collected from Montagu Island, appear to be oceanites, which do not commonly occur in an island-arc environment. The rocks of Freezeland Island which Kemp and Nelson[3] suggested might be sedimentary and metamorphic, proved to be wholly of volcanic origin, the highest peak consisting of stratified volcanic tuff and agglomerate and the lesser peak being formed by a basic dyke. Coarse-grained ejected blocks are rare in the South Sandwich Islands; a few specimens of gabbroic aspect were collected on Leskov and one was found on Vindication Island.

Petrological investigation of the 250 specimens collected from the South Sandwich Islands will be undertaken at the Department of Geology and Mineralogy, University of Oxford.

BOTANY

(R. E. L. and M. W. H.)

On Candlemas Island, Longton made extensive collections of bryophytes and lichens, which predominate in the flora, and surveyed the Island's vegetation. Descriptions of the relatively rich associations around fumaroles were supported by temperature measurements, while three principal plant communities were recognized in inactive areas. The most complex of these was developed on shallow peat deposits which preserved details of plant succession. The reproductive behaviour of certain mosses was examined on Candlemas Island as a part of a wider investigation of their performance in Antarctic environments of differing severity. A 12-ft.-long unworked log was found above high-water mark on the west coast of the Island.

Holdgate made a comparable, less-detailed, vegetation survey on Bellingshausen Island, undertaking temperature measurements around fumaroles. General collections and ecological notes were obtained from Leskov, Visokoi, Vindication, Saunders, and Thule Islands and Freezeland Rock, while a few specimens were also taken at Montagu and Bristol Islands.

In the South Sandwich Islands there is a marked contrast between the comparatively rich, concentrically zoned, vegetation around the fumaroles on Leskov, Visokoi, Candlemas and Bellingshausen Islands, and the generally barren conditions elsewhere. Fumarole vegetation is generally similar throughout the group, but the sparse moss and lichen communities forming the principal vegetation away from the volcanic heat and moisture vary rather strikingly from island to island. Round the large penguin colonies fouled and trampled mud supports mainly algae, particularly *Prasiola*, and areas of bryophyte peat beneath the mud on Candlemas and Vindication Islands suggest that some colonies have changed in area comparatively recently. The grass *Deschampsia antarctica* is known only from between fumaroles on Candlemas Island.

INVERTEBRATE ZOOLOGY

(P. J. T. and M. W. H.)

While on Candlemas Island, Tilbrook made general observations on the fauna as a whole; but concentrated especially on the ecology of terrestrial micro-arthropods and nematodes. Apart from giving much-needed information on the taxa and numbers occurring in the island group, this investigation formed part of a broader survey of the distribution, abundance and ecology of land arthropods of the Scotia Ridge and northern Antarctic Peninsula. All quantitative work (in which the animals were extracted from cores of known volume) was confined to areas of *Polytrichum* and *Bryum* (or *Pohlia*) mats, since these are two of the most widespread genera in these latitudes and had been sampled intensively elsewhere on the Scotia Ridge. These mosses also occurred both around and away from fumaroles, so providing comparable samples in which faunal variation might be related rather directly to a well-marked gradation of environmental factors. Extraction of arthropods on a non-quantitative basis was carried out from samples from many other habitats, including moss mats, lichen tufts, soil, seaweeds, and bird-nest material. Routine plankton and general-purpose net hauls and water samples were taken from all the freshwater bodies on the Island, but marine collecting was virtually impossible owing to the persistent very rough seas.

A less-quantitative extraction technique was used by Holdgate, working aboard H.M.S. *Protector*, to obtain micro-arthropods from Leskov, Visokoi, Vindication, Saunders, Montagu and Bellingshausen Islands. On these islands, mites and Collembola proved to occur locally in large numbers, but to be represented by only a few species. A few freshwater habitats were also sampled on Bellingshausen Island, but appeared unproductive.

VERTEBRATE ZOOLOGY

(R. W. V.)

During the project, investigations were made of the seals and sea birds found in the group. Particular attention was directed to the location of breeding colonies of fur seal, *Arctocephalus tropicalis gazella*, and a census of all seals seen on the islands visited was carried out. A small amount of fur seal skeletal material was collected. In all, five species of seal were seen; but only the elephant and fur seals are certain breeders.

Ornithological work consisted chiefly of the location of breeding colonies on the islands, and the recording of birds seen at sea in the vicinity. Most of the mapping of colonies was done from a helicopter, during flights around the islands: numbers were estimated wherever possible. Landings were made whenever possible, and a careful search was then made for breeding sites of the smaller burrowing petrels. Remains of petrels were collected in the vicinity of skua nests. Some parasites were collected on Candlemas Island, where Tilbrook made a list and census of the breeding birds, paying particular attention to the colonies of giant petrels (*Macronectes giganteus*). Altogether twenty-one species of birds were seen in the vicinity of the islands, but only twelve of these have been confirmed as breeders.

The only whales seen were a few killer whales near Candlemas Island.

ROYAL BOTANIC GARDEN, EDINBURGH

NEW HERBARIUM, LIBRARY AND OFFICES

THE Royal Botanic Garden, Edinburgh, is nearing its three-hundredth anniversary and has had a herbarium and library for perhaps half that time; yet until now they have not been housed in a building designed for the purpose. The old herbarium had once been the meeting room of the Caledonian Horticultural Society, 300 yards across the Garden from library and laboratories: all departments were hopelessly crowded and had overflowed into huts and separated storerooms. Their gathering together into a single building of adequate size cannot fail to lead to a considerable increase in efficiency. The new building is designed to accommodate normal expansion for the next twenty years.

The opening ceremony was performed by Her Majesty The Queen on June 29. The records of this occasion are a signed portrait of The Queen, a rare volume of paintings of Indian plants (1835) by Mrs. James Cookson, especially purchased for the library and autographed by Her Majesty, and a birch tree planted outside the south-west corner of the building. A copy of the first catalogue of plants grown at Edinburgh, the *Hortus Medicus Edinburgensis* of James Sutherland (1683), was presented to Her Majesty.

The building is 143 ft. long and 76 ft. wide, the long axis running east–west. It consists of a two-storey block set on top of a smaller ground floor block: there is a lower ground floor of the same size as the upper storeys. The library is on the ground floor, the herbarium and laboratories on the two upper floors, the administrative offices, storerooms and a small conference room on the lower ground floor. Except for the offices and some storerooms, the building is air-conditioned. It is designed as a framed structure in reinforced concrete with floors and roof of flat slab construction for economy and speed of erection. The external facing material is entirely prefabricated in standardized units of polished white terrazzo and the podium and terrace are finished in warm grey Heworthburn stone with inset panels of grey vitreous tiles. Windows are sealed double-glazed units fixed into black anodized aluminium window-frames. Suspended acoustic ceilings have been used. The architect was R. Saddler, Ministry of Public Building and Works, and the main contractor W. and J. R. Watson, Ltd., Edinburgh.

By using modern techniques of transplanting trees and large shrubs the new building has, within a few months, been assimilated into the Garden with remarkable success.

The library occupies the whole of the ground floor and there is a simple rectangular stack providing about 7,500 ft. run of shelving. Short folio cases form small bays with reading tables along the north wall, and there is another row of reading tables on the south side. Ancillary accommodation consists of an overflow store on the lower ground floor, a workroom and service desk on the main floor. At the entrance to the library is an open area with built-in display racks for current periodicals, reading space, catalogue cabinets, map table and atlas cases. The furnishings are uniform throughout. Bookcases have ends of American walnut which matches the panelling and built-in fixtures. Lighting over the book stack is pro-

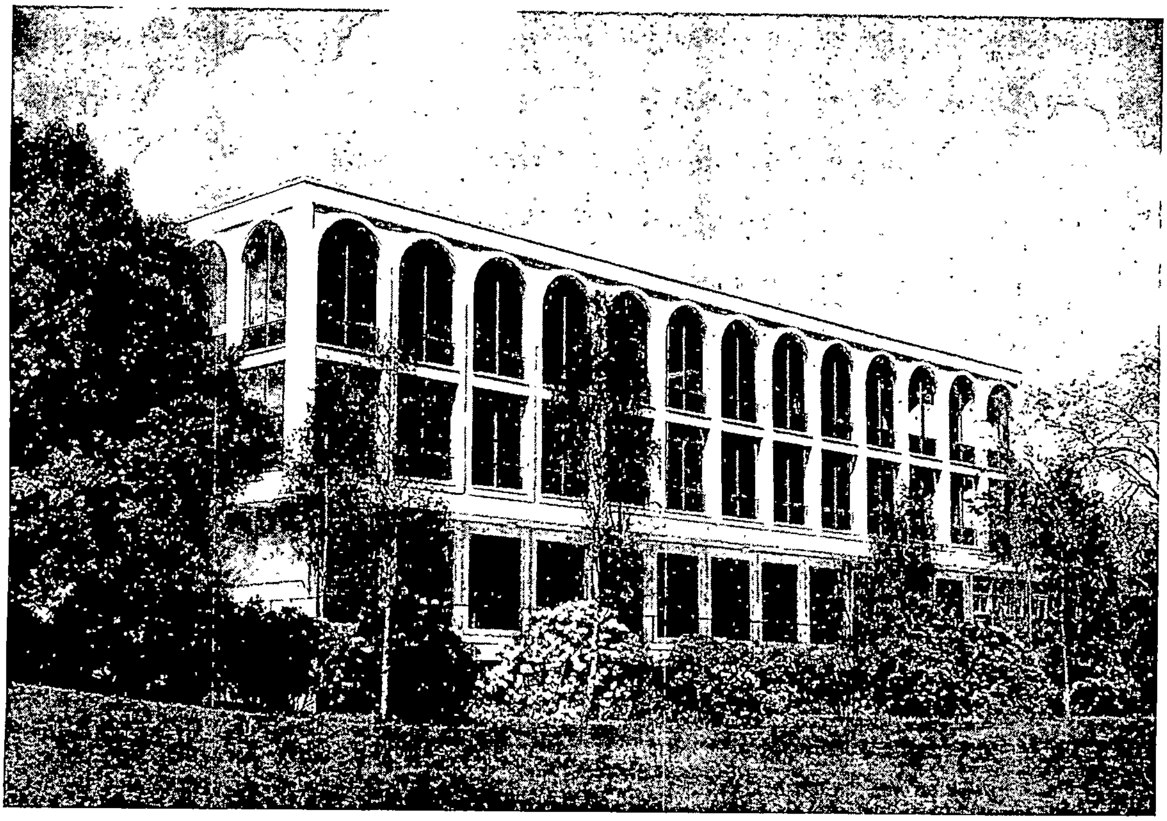

Fig. 1

vided by a suspended illuminated ceiling. The wood block floor is of Rhodesian teak.

The library at present has a stock of 30,000 volumes, two-thirds of which are periodicals. The present intake of periodicals is some 700 titles. For the first time the stock is arranged systematically, the whole library having been re-catalogued over the past seven years according to Bliss's classification. Modifications to this scheme have been kept to a minimum, but some sections have been rearranged—notably by the use of Bentham and Hooker's numbering in systematic botany, so that the arrangement of the books matches that of the herbarium.

A few of the most interesting volumes were on view at the opening ceremony and with them samples of the large collection of photographs and valuable diaries recently bequeathed to the Garden by the late Dr. J. F. Rock, whose plant collections from China are world-famous.

A 22-ft. strip all along the north side of the first floor is cut off from the herbarium to form the photographer's studio and darkroom, workrooms for the two mycologists and the cytologist on the staff, a general laboratory and a culture room. There is an independent air extraction system for this part of the building. The laboratory has working space for 5–6 technical staff and is equipped for all normal routines in mycology, cytology or plant anatomy.

The unity of the herbarium itself, which is split between two floors, is preserved by a small central well; above this there is a raised glass-brick section of roofing with underslung artificial lighting in false beams.

The herbarium is planned for maximum flexibility, with central storage of specimens and peripheral working space. Along the full length of the south side of each floor there is a free consultation bench which is not encroached on for permanent working places for staff; these are distributed around the other three sides of the top floor, and at the two ends of the lower floor.

The herbarium specimens are housed in specially designed steel cabinets: each contains two ranks of six pigeon-holes and they are stacked three high. In order to permit a simple magnetic closure each cupboard has a single door the inner flange of which is fitted with rubber containing a magnetized strip. This system gives effective dust-proofing and most acceptable silence of operation. The absence of catches or locks with moving parts will remove a constant demand for repair work. The single door demands very little more access space than the usual two half-doors, as this is largely governed not by the swing of the doors but by the depth needed to take out specimens. These cabinets are finished in grey stove-enamel and were made and installed by Roneo, Ltd. Roughly one-third of the space is at present free for future accessions.

The herbarium now contains some two million specimens. Among the most interesting of the old collections is that of Paul Dietrich Giseke (1745–96), a pupil of Linnæus; his specimens include several from the garden at Uppsala and one that evidently came from Linnæus's own herbarium and bears his handwriting. Another very valuable herbarium is that of the great Edinburgh botanist Robert Kaye Greville (1794–1866); it contains specimens received from many of his famous botanical contemporaries and is especially rich in cryptogams. It was, however, the collections made in south-west China by George Forrest that gave a new impetus to active taxonomy at Edinburgh, and from these collections there stemmed the work on *Rhododendron*, *Primula* and other Sino-Himalayan genera which brought the Royal Botanic Garden international fame.

Since the Second World War, China has been virtually closed to Western botanists and Edinburgh activity has tended on the one hand towards work on the flora of western Asia (stimulated by P. H. Davis's large Turkish collections), on the other towards the study of special groups.

On the day of the opening ceremony a few small exhibits were put up; one showed the work of G. Forrest, already mentioned; others indicated the travel made by members of the staff in furtherance of present investigations. During the past seven years these have included collecting trips in Turkey, Afghanistan, Pakistan, Burma, Malaya, Sarawak and New Guinea. These were all illustrated by interesting specimens, photographs and living plants—for the introduction of new materials to cultivation in the Garden has been an important aim of these expeditions.

On view in the library were preliminary models and plans of the new greenhouses shortly to replace the existing front range, part of which has already had to be closed to the public for reasons of safety. This is the next phase of modernization at the Garden and will provide better facilities for research collections and even greater incentive to the search for new introductions and for advances in methods of presenting the plant world to students and to the general public.

OBITUARY

Dr. W. O. Howarth

Older members of the University of Manchester and friends throughout Britain will have read with regret of the death at his home in Southport, on June 27, of Dr. W. O. Howarth, formerly senior lecturer in botany in the University of Manchester. He was in his seventy-fourth year and is survived by his wife and son.

Dr. Howarth was at one time a student of the University of Manchester, graduating in 1913. Thereafter he was successively assistant lecturer in botany at University College, Cardiff, and the University of Reading, with a break between during the First World War. He joined the staff of the Botany Department, Manchester, in 1919, and served successively under Profs. Weiss, Drummond, Ashby and Harland, until his retirement in 1956, in all completing upwards of forty years of academic teaching and research. During this period he contributed to the general courses, in particular to plant anatomy and ecology but, especially in his later years, he was responsible for all course work in botany and pharmacognosy for pharmacists. This he did with wide knowledgeability and devotion. In 1925 he was appointed an examiner for the Pharmaceutical Society of Great Britain, and continued in this capacity until after his retirement.

Dr. Howarth, who belonged to a generation of enthusiastic field botanists, was one of the best, his knowledge of the Lancastrian flora, especially of the interesting coastal and adjacent regions around Southport, being unrivalled. In his research he was a recognized authority on some of the genera of grasses. His name is familiar to a very wide circle of botanists through the successful re-issue of Lowson's *Textbook of Botany* (written jointly with the late Dr. L. G. G. Warne). This volume, which has gone through several editions in Britain, was successfully adapted, by the judicious introduction of local examples, for use in India, Pakistan and Ceylon. Howarth also collaborated in the production of a *Practical Botany* for home use and one for use in tropical countries.

To those who knew him well in his daily life, he was greatly liked for his unassuming modesty, an ever-willing helpfulness and quiet, warm friendliness, and for a deep sincerity of purpose in his work. C. W. Wardlaw

NEWS and VIEWS

Director of Observatories Branch, Canadian Department of Mines and Technical Surveys :

Dr. J. H. Hodgson

DR. J. H. HODGSON has been appointed director of the Observatories Branch of the Canadian Department of Mines and Technical Surveys. He has been chief of the Observatory's Seismology Division since 1952. Since joining the Observatory staff in 1949, Dr. Hodgson has specialized in research on the nature of the Earth's crust in the Canadian Shield and investigations of the mechanism of earthquakes. In 1958 he was elected a Fellow of the Royal Society of Canada. He is a member of many national and international organizations, and recently was elected president of the Unesco Intergovernmental Meetings on Seismology and Earthquake Engineering and president of the International Association of Seismology and Physics of the Earth's Interior. Dr. Hodgson was born in Toronto in 1913, and was educated in Ottawa public and secondary schools, and at the University of Toronto. He received a B.A. in applied mathematics in 1940, M.A. in geophysics in 1946, and Ph.D. in geophysics in 1951.

Dominion Astronomer : Dr. R. M. Petrie

DR. R. M. PETRIE has been named Dominion Astronomer in recognition of his outstanding contributions in the field of astrophysics. He joined the staff of the Observatories Branch of the Canadian Department of Mines and Technical Surveys in 1935 and, except for service with the Royal Canadian Navy during the Second World War, has been engaged in astrophysical studies. A large part of his research has consisted of measurement of line-of-sight speed of stars and its application to problems of stellar motion, and the calculation of orbits and dimensions of double stars. Dr. Petrie was educated at primary and secondary schools of Victoria, B.C., and the University of British Columbia, where he graduated with honours in physics in 1928. At the University of Michigan he obtained his Master's degree in 1929 and Ph.D. (astronomy) in 1932. He is a former president of the Royal Astronomical Society of Canada and former vice-president of the American Astronomical Society.

Physics in the University of Manchester:

Prof. J. C. Willmott

DR. J. C. WILLMOTT, reader in physics in the University of Liverpool, has been appointed professor of physics in the University of Manchester, from a date to be arranged, in succession to Prof. E. B. Paul (*Nature*, 189, 876; 1961). Dr. Willmott was an undergraduate in the Imperial College of Science and Technology, obtaining a B.Sc. in 1942, with first-class honours in physics, and becoming an associate of the Royal College of Science in the same year. He then completed his military service, from 1942 until 1946, as a regimental officer in the Royal Electrical and Mechanical Engineers before commencing two years postgraduate study at the Imperial College of Science and Technology on infra-red spectroscopy, for which he was awarded a Ph.D. in June 1949. Dr. Willmott joined the academic staff of the University of Liverpool in 1948 as an assistant lecturer in physics, being promoted to lecturer in 1950, to senior lecturer in 1958, and to reader in 1963.

Applied Mathematics in Queen's College, Dundee:

Prof. D. S. Jones

PROF. D. S. JONES has been appointed to the newly created Baxter chair of applied mathematics at Queen's College, Dundee. Prof. Jones was educated at Wolverhampton Grammar School, from which he went to Corpus Christi College, Oxford, with an open scholarship. His scholastic career was temporarily interrupted by war-time service with the Royal Air Force, during which time he was mentioned in despatches in 1943 and awarded the M.B.E. in 1945. Returning to Oxford, he graduated with first-class honours in mathematics in 1947, and in the same year, having been elected to a Commonwealth fellowship, went to the Massachusetts Institute of Technology. In 1948 he was appointed to the staff of the Mathematics Department at the University of Manchester and in 1954 was given the post of tutor for science. He remained there until 1957 when, at the age of thirty-four, he was appointed to the chair of mathematics at the University College of North Staffordshire, now the University of Keele. Prof. Jones is well known for his work in the field of electromagnetism, in particular the theory of diffraction, and has recently written a book on the subject. He has also written a book on electrical and mechanical oscillations and has published papers on such topics as asymptotic expansions of multiple integrals and theory of unsteady motion of aerofoils. In 1957 he was awarded a D.Sc. by the University of Manchester. In the session 1962–63 he paid a second visit to the Institute of Mathematical Sciences, New York, as the visiting research professor. He has recently been elected a Fellow of the Institute of Mathematics and its Applications. Prof. Jones will take up his appointment on January 1, 1965.

Physiology in the University of Birmingham:

Prof. S. M. Hilton

DR. S. M. HILTON has been appointed to the Bowman chair of physiology in succession to Prof. I. Bush. Dr. Hilton will take up his appointment on January 1, 1965. Dr. Hilton is a member of the scientific staff of the Medical Research Council, and has been in the Division of Physiology and Pharmacology at the National Institute for Medical Research since 1952. Dr. Hilton was born in 1921; he was a senior scholar at St. Paul's School, London, and from there he won an Exhibition to Jesus College, Cambridge. He completed Part I of the Natural Sciences Tripos in 1941, and Part II in 1948. He took the degrees of M.B., B.Chir. in 1944, and Ph.D. in 1956. After qualifying in medicine he held various house appointments at Guy's Hospital and was resident medical officer at Preston Hall Hospital, near Maidstone. His period of national service was spent at the Royal Air Force Institute of Aviation Medicine, during which time he was also a research assistant in the Department of Physiology at the Royal College of Surgeons. In 1950, after leaving the Royal Air Force, he worked for two years in the Department of Physiology at Cambridge and was in receipt of a personal grant from the Medical Research Council. Dr. Hilton's main field of research has been the circulatory system, with particular regard to mechanism of the changes in blood flow occurring in organs and tissues during activity. Recently he turned from the investigation of local chemical and nervous factors involved in such reactions to that of their regulation by the central nervous system, and the integration of cardiovascular responses in the behaviour and physical activity of the conscious animal.

Royal Society Expedition to the Solomon Islands

THE Royal Society has announced its intention of mounting a scientific expedition to the British Solomon Islands Protectorate in 1965. Little is known of the arc of islands from New Guinea, New Britain, the Solomon

Islands, New Hebrides, New Caledonia to New Zealand, and it is thought that a source of information of great value, which might provide the key to problems of biological distribution and ecology in this area, could be found in the Solomon Islands. Much of these extensively forested Islands has not yet been seriously disturbed by man, but its forests are already attracting the attention of those who wish to exploit them commercially, so that it is a matter of some urgency to investigate them while present conditions last. An examination of existing knowledge indicates that the first expedition to the Solomon Islands might most profitably spend about six months in the field, and consist of a marine party of about six to seven scientists to study the shallow water and shore-line biology, and a land party of about eight botanists and zoologists to concentrate on the densely forested interiors and the altitudinal variations. Areas for intensive investigation have been selected on the Islands of Guadalcanal, San Cristoval, Ysabel and Kolombangara, and the marine party will concentrate on areas of the shores of these islands together with New Georgia and Russell Island. The plans for the expedition are proceeding. The expedition will be led by Mr. E. J. H. Corner (Cambridge), who will also lead the land party, while the marine party will be under the leadership of Prof. J. E. Morton (Auckland). The personnel will include scientists from Britain, Australia and New Zealand, some of whom have already been selected, as well as scientists from the British Solomon Islands Protectorate Government Departments of Forestry, Agriculture and Geology. The planning of the expedition is in the hands of the Southern Zone Expeditions Committee of the Royal Society and a small planning group appointed by the committee, comprising the chairman of the committee, the leader and the executive secretary of the Royal Society. The logistics and field organization of the expedition will be the responsibility of Mr. G. E. Hemmen, expeditions officer of the Royal Society, and it is expected that the expedition's boat will be the M.V. *Maroro* from Fiji, under the command of her owner, Captain S. B. Brown.

National Institute of Agricultural Engineering

An informal meeting was held on July 24 at the National Institute of Agricultural Engineering, Wrest Park, Silsoe, at which Sir Harold Wernher, chairman of the Institute, made a presentation on behalf of the staff to Mr. W. H. Cashmore in view of the latter's retirement from the directorship of the Institute on July 31. Presentations were also made to Mr. J. W. Andrews, secretary, and to Mr. R. V. Hussey, who were also retiring. Those present included the Hon. J. J. Astor, J.P., chairman of the Governing Body, and Mr. C. J. Moss, director designate.

Medical Research Council New Research Unit and Research Groups

The Medical Research Council has recently announced the establishment of a new research unit and of three new research groups: *The Cell Genetics Research Unit* will be set up in the Department of Genetics in the University of Glasgow, under the honorary direction of Prof. G. Pontecorvo. The Unit will undertake research on the use of human and other mammalian cell cultures as a tool in genetic analysis. *The Oculogenital Virus Research Group* has been established at the Institute of Ophthalmology, University of London, under the honorary direction of Prof. B. R. Jones. The Group will be engaged on research on the trachoma-inclusion conjunctivitis agents, with particular reference to the relationship between infections of the genital tract and infections of the eye. *The Research Group in Basic Immunology* has been set up in the Department of Experimental Pathology, University of Birmingham Medical School, under the honorary direction of Prof. P. G. H. Gell. The Group will be mainly concerned with fundamental research in immunology and immunogenetics, with particular reference to the activities of cells in mediating immune responses. *The Thrombosis Research Group* will be established at the Institute of Basic Medical Sciences, the Royal College of Surgeons, under the honorary direction of Prof. G. V. R. Born. The Group will be concerned with research into chemical substances which promote or prevent the adhesion and aggregation of platelets in the blood and affect the formation of thrombi.

Political and Economic Planning

The annual report of Political and Economic Planning for the year ended March 31, 1964, notes that all five major current projects are due for completion in the next few months; an investigation has been made both of the organization's methods of working and of the appropriate balance between intensive studies and policy reviews (Pp. 17. London: Political and Economic Planning, 1964). Policy review groups are being set up on fuel and world population, and a number of new major projects within the general ambit of "The Shape of the Sixties" are being considered. Under the programme of work on Britain and the European Common Market, started in September 1958, there were three publications during the year, and a book-length report on economic planning and the European economic community is being prepared. A full report on the examination of community mental health services is also in preparation, and completion of another dealing with an investigation of prisoners and their families is also expected this summer. A final report on attitudes in British industry is expected to be published by the end of the year, and the report on "Education for a Developing Region" is to be followed by one giving the findings of the investigations in the United Kingdom. Publication of the results of a three-year study, *Trade Unions in a Changing Society*, started in October 1960, was completed with the issue of three Broadsheets during the year (*Nature*, 200, 817; 1963).

Scientific American Offprints

Offprints of articles published in *Scientific American* are selling in increasingly large quantities throughout the world, particularly in the United States, where they have been adopted in many colleges and universities as supplementary material for text-books, some of which become out of date quickly. The articles are written by leading scientists actively engaged in research. Recently issued offprint booklets range in subject from fundamental particles in physics to recent research on the mechanism of the human body in conserving the oxygen supply to the brain at times of threatened asphyxia. In each the English style is clear and simple, the argument is presented logically and succinctly, and the presentation with regard to printing diagrams is of a high quality. The documentation is useful and sufficient. In the United Kingdom, offprints are obtainable from W. H. Freeman and Co., Ltd., Warner House, 48 Upper Thames Street, London, E.C.4. *Catalogue* No. 4, 1964, contains a list of 865 titles arranged under subject headings, and there is an author index. The offprints cost 1*s*. 6*d*. each and cover the life sciences, chemistry, physics, technology, psychology, the social sciences, the earth sciences and the history and philosophy of science. The booklets are to be welcomed both as aids to teachers and students, who wish to keep abreast of their subjects, and to the scientific reader who wishes to keep in touch with developments in disciplines other than his own.

Magazine of Concrete Research

With the March issue of this well-known publication of the Cement and Concrete Association (16, No. 46; 1964), it now becomes a quarterly instead of a four-monthly journal, and to mark this change it appears with a new cover design; the internal appearance of the *Magazine* remains, however, unchanged. The reasons are common to the task of many editors of scientific journals, among which are the increasing number of papers selected and recommended for publication, in this case by an independent advisory board; the endeavour to contain this material within the bounds of the *Magazine* itself; and the consequent increasing lapse of time between the receipt of a manuscript and its appearance in print. Another factor in the situation is that latterly discussions of papers published have tended to be crowded out by the pressure of new contributions awaiting publication. A further innovation in this *Magazine* is described in the editorial comment: "This ever-increasing volume of published material presents the research worker and the librarian with problems in their turn. However, to offset the extra contribution which the *Magazine* will be making in future, it has been decided to include abstracts of the articles appearing in the *Magazine*, and this issue contains the first of these abstracts. The abstracts themselves are printed on a separate sheet so that their removal from the *Magazine* will not spoil its appearance in any way". The abstracts are the authors' own summaries; they are printed on pale-green card, each comfortably contained within a delineated area of 6 × 4 in., which can easily be cut out for card-indexing. This is a feature which could well be copied in other technical journals to facilitate quick reference. The editorial advisory board, equally the Editor himself, are to be congratulated on the determination and pursuit of a policy which can only serve to enhance the prestige and long-proved value of this excellent publication.

The Museums Journal

VOL. 64, No. 1, of *The Museums Journal* is devoted to the scientific aspects of the work of museums and art galleries. In this field, science has two functions—the conservation of objects in the museum and the preservation of the apparatus used by the early scientists. Dr. A. E. Werner deals with some of the endless variety of materials now available for conservation work, and Mr. G. Thomson with the chemical and physical aspects of the changes which occur in various objects. Mr. S. Slabczynski describes a moderately sized laboratory for the restoration of paintings, and Mr. F. Greenaway gives an admirable illustrated description of the new Chemistry Gallery at the Science Museum, Kensington. Mr. N. W. Bertenshaw similarly describes the Industrial Museum at Birmingham and touches on the basic principles involved in the establishment and maintenance of such museums, while Mr. B. J. Ford details a new technique for mounting museum specimens which consists of sealing a jar by means of a solution of polystyrene in xylene. The annual report of the Council of the Museums Association for 1963–64 concludes an especially interesting number.

Man as a Subject for Science

THE sixth Auguste Comte Memorial Lecture was delivered by Prof. A. J. Ayer at the London School of Economics and Political Science on February 7, 1964, under the title "Man as a Subject for Science" (Pp. 26. London: The Athlone Press, University of London. Distributed by Constable and Co., Ltd., 1964. 5*s*. net). Pointing out that the social sciences can only muster a comparatively small stock of generally accredited and well-tested theories, Prof. Ayer suggests that their relatively poor stock of generalizations may be due to something inherent in the material with which social scientists have to work. He recognizes that this idea must be received with caution and that the issue of determinism must be decided. The important question is whether human behaviour is, or is not, entirely subject to law. In discussing this, Prof. Ayer does not accept as necessarily true the common belief among philosophers that motives are not causes and suggests that causal relations should be regarded as holding between facts rather than events—where 'fact' is understood in the wide sense in which true propositions of any form can be taken as expressing facts. He does not, however, think that the issue of determinism should be interpreted as an *a priori* question. The strength of the determinists lies in the fact that there seems to be no reason why the reign of law should break down at this point, though this argument seemed more convincing in the age of classical physics than it does to-day; that of the indeterminists lies in the fact that the specific theories which alone could indicate or give any substance to their opponents' case have not yet been more than sketched. Until such theories are properly elaborated and tested, Prof. Ayer thinks that there is little more that can usefully be said about this topic. As to whether the denial of determinism is implied in our usual ascriptions of moral and legal responsibility, in so far as this is a question of what people actually believe, Prof. Ayer is now inclined to believe that the antithesis between the claims of free will and determinism is not illusory but that our ordinary ideas of freedom and responsibility are very muddle-headed although firmly held. It would not be at all easy to estimate the social consequences of discarding them.

Man, the Social Animal

THE first part of K. W. Monsarrat's *On Human Wisdom* is concerned with man's innate ideas regarding the nature of and the structure of what he names "I myself" and "the world", including his attempts to give subjective and objective accounts of both and the value of the relative truths given to man by his validity judgments (Pp. 24. Liverpool: Henry Young and Son, Ltd., 1964. 6*s*.). The second part is concerned with man in his social relations, discussing the dependence of the stability of social groups on the quality and degree of aid which the individuals composing them have given to each other and emphasizing that, on the national level, the attainment and retention of prosperity depend on the Government being concerned for the welfare of all its members and seeking agreements on the rewards due for the various types of work they perform. He sees the pattern of Government needed as provided in microcosm by the physiological account of the function performed by the nervous sub-system in organizing the dynamic relations between the organs comprising the individual. Reviewing briefly Britain's social history and the functioning of the Coalition Government in the Second World War, Mr. Monsarrat postulates for the future Government of Britain a cessation of party conflict within Parliament; a Parliament of men whose overriding interest is the cultivation of mutual aid and friendship in all home affairs and who will call on the whole people to unite in a war-effort against war and disease in any nation, and undeterred by any alliance from including in its offers of aid and friendship the U.S.S.R., China or any other nation. Such a Parliament could plan a more promising effort to prevent global war than sending delegates to a disarmament conference. It would also implement a fair-shares-of-wealth policy, firmly based on the value of contributions to the nation's well-being and on the education and training needed for different types of work.

Leukopoiesis in Health and Disease

ARTICLE 2 of Volume 113 of the *Annals of the New York Academy of Sciences* is entitled "Leukopoiesis in Health and Disease" (By Howard R. Bierman and 124 other authors. Pp. 511–1092. New York: New York Academy of Sciences, 1964. 8 dollars). The forty original papers in this volume (one of the largest in the series) were presented at a conference in May 1963. The origin and formation of the white cells of the blood have been the subject of increasingly concentrated research in recent years, and this collection gives a cross-section of present trends. Certain widely influential notions have strongly influenced attitudes and methods in this field; for example, fluctuations in the relative or absolute numbers of white blood cells in health or disease are regarded as disturbances of an underlying homœostasis, and it is the mechanism of the latter which receives most attention. The use of radioactive tracers has given to the investigation of the formation, circulation and recirculation, and final disposal, of blood cells a new power and precision. Short-term culture of blood or marrow cells in the presence of phytohæmagglutinins has made possible chromosome analysis of normal and leukæmic cells (five papers deal with chromosome abnormalities). New surgical techniques for prolonged collection of thoracic duct lymph have made quantitative examinations of lymphocyte production possible, and the use of these, together with radioactive labelling, promises a solution of the old problem of the life history and function of the lymphocyte in the not-too-distant future (four papers deal with lymphocyte kinetics). The foregoing are some of the subjects covered by this large and varied collection of articles. Though they are, for the most part, records of new work or progress reports, and only incidentally review past work, the volume as a whole gives a good conspectus of this fertile field of research.

Architecture of the Oviduct of the Domestic Hen

According to its gross appearance, the oviduct of the domestic hen can be divided into several parts. Romanoff has described the infundibulum, the albumen secreting region (magnum) and the isthmus, while Sato, Koso and Osaki have noted a narrow part between the infundibulum and the magnum. On the other hand, the hen's egg consists of yolk, chalaziferous layer, layers of albumen, shell membrane and the egg shell. It is known that the chalaziferous layer is formed in the oviduct before the albumen secreting region, that the major part of the albumen layer is formed in the magnum, and that the shell membrane is formed in the isthmus. Consequently, it is expected that the structure, function and the product of the oviduct will present marked differences in the various segments. Histological and cytological investigations of the hen's oviduct, however, are still limited and fail to demonstrate local specialization of the oviduct. An investigation by Kazuaki Misugi and Tadashi Katsumata, of the First Department of Anatomy, Yokohama University School of Medicine, Yokohama, describes the electron microscopical characteristics of the cells composing the main segments and correlates these with the different types of proteins forming the egg (*Yokohama Medical Bulletin*, 14, No. 6; December 1963). The description is confined to the electron microscopic examination of the secretory cells in an active stage of secretion and reveals that the segments are composed of different cells and show segmental specialization. This segmental morphology may be correlated with the functions of the respective segments in the formation of the egg.

The Effect of Isoniazid on Protein Synthesis of *Mycobacteria*

Michio Tsukamura and Sunio Tsukamura of the Obuso National Sanatorium, Obu, near Nagoya, Aichi-ken, Japan, have observed the effect of isoniazid on the protein synthesis of *Mycobacteria* (*Jap. J. Tuberc.*, 11, Nos. 1–4; December 1963). Their investigations show that incorporation of radioactive glutamic acid into protein is inhibited by isoniazid at a concentration of 20 μg/ml. This means that protein synthesis in the organisms, *Mycobacterium* 'Jucho' and *M. tuberculosis*, is inhibited by isoniazid. The effect of this drug on the incorporation of amino-acids into protein is heterogeneous; incorporation of glutamic acid was inhibited, while incorporation of glycine and leucine was not inhibited. It was shown also that α-ketoglutarate is converted to glutamic acid and then incorporated into protein. The former was not inhibited, but the latter was inhibited by isoniazid. It is still not clear whether the inhibition of protein synthesis is a primary effect of isoniazid. The finding that incorporation of α-ketoglutarate into the nucleic acid fraction was also inhibited by isoniazid makes it difficult to draw a definite conclusion. It is remarkable that the pattern of distribution into cellular fractions of radioactivity from incorporated α-ketoglutarate differs significantly from the pattern of acetate. Most parts of radioactive acetate-1-^{14}C were incorporated into the lipid and protein fractions, whereas only a small part of the keto acid was incorporated into the lipid fraction. However, this pattern of incorporation of the keto acid is different in *M. tuberculosis* from that of *M.* 'Jucho'. In *M. tuberculosis* a large amount of the keto acid could be incorporated into the lipid. It is thus probable that the pattern of lipid synthesis in *M. tuberculosis* differs from that of *M.* 'Jucho'.

Australian Mineral Industry

The Australian Bureau of Mineral Resources, Geology and Geophysics, among its other official publications, issues periodically *The Australian Mineral Industry—Quarterly Review* in which reasonably up-to-date information on production of selected minerals and metals and on smelter and refinery production can be sought. A recent copy (16, No. 3; March 1964) contains appropriate data (up to February 1964) on fuels (black and brown coal and petroleum); metals: aluminium, antimony, copper, gold, iron and steel, lead, manganese, monazite, tin, tungsten and zinc. In the section on industrial minerals, are included details of asbestos, gypsum, ilmenite, nitrogenous fertilizers, phosphates, rutile, sulphur and zircon. There is a keen overseas demand for Australian opal, with Japan the principal buyer, which, in the third quarter of 1963, rose to the highest value ever recorded in a three-monthly period, nearly three-quarter million pounds sterling. Part 2 of this publication contains statistics relating to Australian production of and overseas trade in minerals and mineral products for the quarter ended September 30, 1963. In addition to the *Quarterly Review*, the Bureau also publishes an *Annual Review*; this surveys the industry as a whole and comprises a general review, review of metals and minerals, and general statistics as available for each year.

Mineralogy in Japan

Progress in research in mineralogy in Japan can be followed in periodic publications of the Mineralogical Society of Japan (Chigaku Center, Niban-chô, Chiyoda-ku, Tokyo). The *Journal of the Mineralogical Society of Japan* (*Kôbutsugaku Zasshi*) contains articles and reviews on mineralogy and allied sciences in Japanese contributed by members of the Society, and is published every four months. The *Mineralogical Journal* is a half-yearly publication, principally in English, and is therefore probably of wider appeal than the *Journal* of the Society itself; it invites contributions from everyone. In the issue recently received (4, No. 1; February 1963), H. Shirozu contributes a paper on structural changes of some chlorites by grinding, in particular the unusual sensitivity found in the orthohexagonal iron chlorites attributed to this cause; T. Murano discusses radioactive equilibrium in the Ningyotoge uranium ores, especially between ionium and uranium; A. Kawahara describes his X-ray studies on some alkaline amphiboles (arfvedsonite and riebeckite), with somewhat surprising optical results; K. Hayase, R. Ōtsuka and T. Mariko contribute an important paper on the magnetic properties of natural pyrrhotite; among other conclusions they draw from results of considerable experimental work on this notoriously variable species, is that naturally occurring pyrrhotite is a mixture of 'peak-' and 'Weiss-type' pyrrhotite grains and the magnetic properties of the mineral change with the ratio of one to the other occurring therein. A valuable addition to these papers is the inclusion of mineralogical abstracts from scientific papers published in Japan (1960–62). The English rendering throughout the *Mineralogical Journal* is generally good; the presentation of the papers with their illustrations (mostly line-drawings), while perhaps not attaining the high standard achieved by its contemporaries in mineralogy in Western countries, is none the less reasonably satisfactory.

University News: Belfast

THE following appointments to lectureships have been announced: Dr. P. M. Robinson (botany); A. Refsum, Dr. P. D. Roberts and Dr. G. Williams (electrical engineering).

Birmingham

THE following appointments have been made: *Lectureships*, Dr. M. R. Daniel (physics); C. Fraser (social psychology); Dr. G. G. Henshaw (botany); M. Jobes (physics); M. C. Scott (physics); Dr. Heidi H. Swanson (anatomy); *Research Fellowships*, J. G. Allen (anatomy); Dr. N. A. Bukhari (chemistry); A. J. Collings (medical biochemistry and pharmacology); J. D. Davies (physics); Dr. J. C. Dore (Nuffield Research Fellow in the Department of Physics); G. J. Hawkins (electronic and electrical engineering); P. Hicken (pathology); J. Insley (Senior Research Fellow in the Institute of Child Health); D. A. Jackson (physics); E. W. Taylor (zoology and comparative physiology), J. E. Williams (industrial metallurgy).

London

MR. J. D. SARGAN, reader in econometrics in the London School of Economics and Political Science, has been appointed to the chair of econometrics tenable at that School. Dr. P. H. Venables, of the Medical Research Council–Social Psychiatry Research Unit, has been appointed to the readership in psychology tenable at Birkbeck College. Titles have been conferred as follow: reader in physiology, on Mr. J. E. Pascoe in respect of his post at University College; reader in sociology (with special reference to criminology), on Dr. T. P. Morris in respect of his post at the London School of Economics and Political Science; professor of sociology (with special reference to politics), on Dr. R. T. McKenzie in respect of his post at the London School of Economics and Political Science.

Royal College of Science and Technology, Glasgow

THE annual report of the Royal College of Science and Technology, Glasgow, for 1962–63, covering the 167th session, records a total of 2,004 full-time and 2,150 part-time students, compared with 1,997 and 2,546, respectively, in 1961–62; the number of part-time students has steadily fallen from 3,241 in 1959–60 (Pp. 95. Glasgow: The Royal College of Science and Technology, 1964). In his foreword the principal, Dr. S. C. Curran, refers to the Government's announcement that the College was to be given full university status and the choice of the name, the University of Strathclyde, with Lord Todd as first Chancellor. An imperative need stemming from the developments now proceeding is that of student residences, where the College is at a grave disadvantage. Discussions with representatives of the Scottish College of Commerce are examining the possibility of amalgamating that College with the new University. Besides lists of publications, Council and heads of departments, the report includes the usual departmental reports which refer to the increasing volume and scope of the research effort. Dr. Curran refers particularly to the start-up of the reactor at the East Kilbride Research Centre in a collaborative venture with the Scottish universities and the Queen's University, Belfast, and supported by a large grant from the Department of Scientific and Industrial Research. Further details of present research work are given in a separate *Report on Research 1962–63*, which also includes lists of publications and titles of theses approved for higher degrees, arranged under Departments (Pp. 53. Glasgow: The Royal College of Science and Technology, 1964).

The Night Sky in September

NEW moon occurs on Sept. 6d 04h 35m U.T. and full moon on Sept. 21d 17h 31m. The following conjunctions with the Moon occur: Sept. 2d 13h, Mars 1° S.; Sept. 2d 16h, Venus 5° S.; Sept. 19d 11h, Saturn 3° N.; Sept. 25d 19h, Jupiter 1° N. Venus is in conjunction with Pollux on Sept. 2d 14h, Venus being 9° S., and Mars with Pollux on Sept. 5d 05h, Mars being 6° S. Mercury is a morning star, rising nearly two hours before the Sun on Sept. 20; it is visible low in the south-east before sunrise, and may be observed during the last three weeks of the month. Venus is a morning star, rising at 1h 10m, 1h 25m and 1h 55m on Sept. 1, 15 and 30, respectively. Its stellar magnitude is $-3{\cdot}8$; its distance from the Earth increases during the month from 67 to 89 million miles and the visible portion of the apparent disk from 0·516 to 0·654. Mars rises at 0h 45m, 0h 30m and 0h 20m at the beginning, middle and end of the month, respectively. Its stellar magnitude is $+1{\cdot}6$, and conditions for observation are becoming more favourable. Jupiter rises at 21h 10m, 20h 15m and 19h 15m on September 1, 15 and 30, respectively. It is near the boundary between Aries and Taurus, its stellar magnitude is $-2{\cdot}2$ and its distance from the Earth on September 15 is 415 million miles. Saturn sets at 4h 20m, 3h 25m and 2h 20m at the beginning, middle and end of the month, respectively. It is in Aquarius, moving westwards among the stars. Its stellar magnitude is $+0{\cdot}7$ and its distance from the Earth on September 15 is 822 million miles. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Sept. 1d 02h 28·8m, 3 Gem. *m* (*R*); Sept. 18d 20h 25·5m, κ Cap. (*D*); Sept. 29d 00h 20·8m, 87 B. Gem. (*R*). *D* and *R* refer to disappearance and reappearance, respectively. The autumnal equinox occurs on Sept. 23d 00h 17m.

Announcements

THE fourth annual general meeting and conference of the Society for Folk Life Studies will be held in Cardiff during September 11–13. Further information can be obtained from J. Geraint Jenkins, Welsh Folk Museum, St. Fagans, Cardiff.

THE thirty-eighth annual conference of Aslib entitled "Looking Forward in Documentation" will be held in the University of Exeter during September 28–October 1. Further information can be obtained from Aslib, 3 Belgrave Square, London, S.W.1.

A MEETING of the British Society of Rheology will be held in the University of Exeter during September 28–30. Papers will be presented on rheometry and the teaching of rheology. Further information can be obtained from Dr. M. F. Culpin, 8 The Broadway, Pontypool, Monmouthshire.

THE fifth course in "Histochemistry", arranged by L'Institut d' Histochemie Médicale, will be held in Paris during September 28–October 10. Further information can be obtained from the Secrétariat de l'Institut d'Histochemie Médicale, Nouvelle Faculté de Médecine, 45 rue des Saints-Pères, Paris 6.

A SYMPOSIUM on "The Application of Chemical Engineering in Newly Developing Countries", organized by the Institution of Chemical Engineers, will be held in London on September 29. Further information can be obtained from O. G. Weller, Institution of Chemical Engineers, 16 Belgrave Square, London, S.W.1.

ERRATUM. In the communication entitled "Allelism of Silver, Gold, and Imperfect Albinism in the Fowl" by Prof. R. K. Cole and T. K. Jeffers, which appeared on p. 1238 of the December 31, 1963, issue of *Nature*, lines 13 and 14 should read ". . . Identical linkages (7·0 per cent) were . . . ".

A COMPREHENSIVE SCHEME FOR THE QUALITY CONTROL OF DRUGS AND MEDICATED PRODUCTS

THE following scheme for the quality control of drugs and medicated products was drawn up by a technical committee of the Pharmaceutical Society of Great Britain and deals with, in its widest aspects, the testing of drugs from the stage of their importation or manufacture to the delivery of the dispensed medicine to the patient. The report has been submitted by the Society to the Ministry of Health.

As a consequence of its earlier consideration of various aspects of quality control applicable to drugs and medicated products, the Science Committee (Pharmaceutical Analysis) of the Pharmaceutical Society of Great Britain was requested in June 1963 to prepare a model drug-testing scheme to be operated in the United Kingdom. It seemed expedient and proper to consider a more comprehensive scheme than those now operating to ensure that all drugs supplied to the public, in whatever manner, should be controlled.

In addition to the sampling and testing of drugs (a necessary process in any system of quality control) provision is planned for inspecting, licensing and registering premises in which drugs are manufactured, compounded or stored. A proposal for controlling imported drugs is also included. To make such control effective, the Committee envisages the establishment of a Directorate having the necessary legal powers with inspection and with laboratory facilities. (Detailed considerations of the legislation required and of the financing of the project were considered to be outside the terms of reference of the Committee.)

In presenting its proposals, the Committee realizes that expediency may require these proposals to be modified for an interim period during which, for example, it may be necessary to correlate them with existing legislation and to use some of the existing machinery for testing drugs. Nevertheless, this period should be strictly limited and no modification should violate the basic principle that all drugs supplied to the public should be subject to scrutiny.

REGISTRATION AND LICENSING

The bodies over which some degree of control will need to be exercised include: drug manufacturers; medicated product manufacturers; importers of drugs both in bulk and as formulated products; drug wholesalers; hospital manufacturing and dispensing units; medical, pharmaceutical, dental and veterinary practitioners who carry out dispensing; clinics, and all retailers handling drugs. The purpose of registration and licensing is to ensure, so far as is reasonable, that any premises used for the manufacture, warehousing or distribution of drugs are satisfactory. The issue of a licence to manufacture, import or distribute will depend on the acceptance of the principle that the accredited representative of the Executive Organization has a right to enter, inspect and take samples. Re-licensing will be necessary following a change of ownership. Since the deterioration of drugs during storage is a major reason for the sale of poor-quality drugs, the adequacy of warehouse and other storage facilities requires attention.

Manufacturing Units

The registration and licensing of premises to be used for the manufacture of drugs in bulk or as formulated products, including medicated toilet preparations, will depend on the general level of hygiene and management. The maintenance of an efficient system of internal control records, open for inspection, relating to the various products is an integral part of a control operation. The existence of a scheme adequate for tracing the origin of any batch of drug or medicinal preparation should be a part of any internal record system.

Premises. These will be subject to inspection or approval before a licence to manufacture drugs is issued. The facilities available and the condition of the premises will determine the decision of the Executive Organization. The issue of a licence will be for a limited period of, say, three years, after which renewal will be necessary. As it is imperative that there be some measure of control of the raw materials, including packaging materials, right of entry to the premises must be allowed to inspectors appointed by the Executive Organization. Such inspectors must also have access to the production records and be given the powers to take any necessary action.

Personnel. The complexity of modern pharmaceutical industry necessitates that effective supervisory responsibility for drug manufacture be taken by highly qualified and experienced personnel. The manufacture of bulk drugs should be controlled by professionally qualified persons, such as chemists, pharmacists or chemical engineers, while the manufacture of medicated products in industry and in hospital practice should be the responsibility of pharmacists or chemists having appropriate experience. This supervisory staff should be listed by the Executive Organization, who would be informed immediately of any change in personnel. As an interim measure only, the Committee considers that a list of technicians and other experienced operatives, not qualified in the professional sense, be compiled. Such people may be granted responsibility for supervisory control where it can be shown that they have had the necessary supervisory experience within the industry for a period of not less than five years before the date of the inception of this scheme.

Warehouses and other Storage Units

Experience in the pharmaceutical industry has shown that there can be a considerable delay between the manufacture of a medicated product and its utilization by members of the public. The instability of certain drugs and the products containing them makes it imperative to have proper conditions of drug storage in order to avoid deterioration.

Bulk drug manufacturing units. The right to inspect storage areas is implicit in the issue of a licence to the drug manufacturing organization, since it is important that the drugs should not be subject to rodent infestation or other contamination, or to extreme moisture and temperature conditions.

Hospital manufacturing units. The quantities of bulk drugs in these units will be relatively small and storage in the pharmacy may be adequate. If it is necessary to store outside the pharmacy the factors under the foregoing "Bulk drug manufacturing units" must be taken into account.

Wholesalers' warehouses. These premises must be subject to the same control as for "Bulk drug manufacturing units". Special attention will have to be directed to the establishment of a satisfactory system designed to prevent the accumulation of old material, and to products carrying an expiry date.

Importers' warehouses. Since comprehensive inspection of foreign manufacturers' premises is not, in general, practicable, some control will need to be exercised when the product is landed in the United Kingdom. Warehouses at the docks and airports will require registration and be subject to inspection, etc. Appropriate information on the commodity is required. A separate clearance certificate will be necessary on each occasion. While bonded warehouses into which imported drugs will go pending their clearance will not normally be subject to inspection and registration, it is considered that the full co-operation of the Board of Trade in disclosing such importations will be required and that the storage conditions are suitable. The rejection of unsatisfactory imports at this stage could prevent their transfer to the importers' warehouses.

Outlets to the Consumer

As the purpose of a comprehensive quality control scheme for drugs is that a pharmaceutically satisfactory product be made available to the public, some inspection control must be exercised at this point of distribution. The distribution points are concerned with the unrestricted purchase of medicated products. Typical examples are pharmacies, drug stores, listed sellers, etc. An important contact point is that which occurs following the presentation of a prescription in either medical, pharmaceutical, dental or veterinary practice.

Sale by retail. The Committee feels some concern at the present situation where it is now possible to purchase drugs and medicated products from stores, grocers, market stalls, licensed premises, etc., where control is exercised by people with little or no knowledge of the problems associated with the drugs. The use of vending machines inadequately protected from the weather and granting easy access to drugs is to be deplored. It is therefore essential that all premises used for the sale of drugs should be registered and subject to inspection and approval.

Dispensaries. Dispensaries may be in retail shops, doctors' surgeries, hospitals or clinics. All such premises in which prescriptions from members of the medical, dental or veterinary professions are dispensed should be registered and open to inspection by the representatives of the Executive Organization.

SAMPLING AND TESTING

The object of sampling and testing is to provide an effective check on the quality of drugs being offered to the public as prepacked drugs, formulated products and dispensed preparations, etc., and to determine the source and nature of any defect. The range of products to be controlled comprises raw materials, drugs and packaging materials, formulated products, surgical dressings and sutures, medicated cosmetics and toiletries, medicated veterinary preparations, dispensed medicine and equipment for which claims for sterility are made. In the opinion of the Committee the functional testing of appliances is outside the scope of this quality control scheme. Inspectors must be empowered to sample at any stage of production or formulation and to sample the finished product at any point between the manufacturer and the consumer. By using proper control records, as stipulated, any defect that is revealed can be traced to its source. Where adequate records by manufacturers and importers exist, and are available for inspection, the extent of sampling may be reduced.

Sampling Techniques

Where a sample can be divided into replicate portions, it should be divided into three by the inspector in the presence of a responsible person. One portion should be handed to the person from whom the sample was obtained and the remaining samples taken away by the inspector. Of these two samples, one would be the subject of examination by the official analyst and the other would be retained as reference sample for independent testing should this be necessary. It is essential that each sample should be sealed, and clearly identifiable. The present sampling technique that is operated under the Food and Drugs Act would be applicable to general sampling under this scheme. For dispensed medicines, the sampling procedure detailed in Part 1 of the Seventh Schedule of the Food and Drugs Act, 1955, would possibly be suitep after the preliminary procedure specified under the Ministry of Health E.C.L. 7/61 Appendix 1, para. 6 (*a*). Informal sampling for the purposes of obtaining general information is not precluded from the scheme.

Raw materials (*chemical and packaging materials*). Evidence on the quality of raw materials (and the packaging materials) could be obtained from the inspection of manufacturers' control records. Samples will be taken where, in the opinion of the inspector, doubts as to quality exist. In this connexion the use of such terms as *British Pharmacopœia* (B.P.), *British Pharmaceutical Codex* (B.P.C.), etc., demands complete compliance with the official monograph.

Formulated products (*medical, veterinary or cosmetic*). The routine sampling of manufacturers' stocks should be unnecessary where inspection of the internal control records indicates proper supervision and regular control. Where little or no analytical control is exercised, consultant-analyst certificates would give an indication of the extent to which products might need further examination.

An indication of product stability is of importance and attention will need to be directed to an expiry date to be applied to those products for which prolonged storage is undesirable.

Wholesalers' stocks. Probably only a few samples will need to be taken from the wholesalers' stocks, although the inspectors will have to ensure that the conditions of storage are satisfactory.

Importers' stocks. Importers of bulk drugs and formulated products should provide adequate information on: (*a*) specification of the raw materials used; (*b*) details of product manufacture; (*c*) details of product specification and control directions; (*d*) product stability; (*e*) intended procedure for distribution of stocks. Importers must supply samples on request. All imports should be submitted to some form of control as early as possible and each batch of each product must have an acceptable certificate of analysis. It is envisaged that protocols of analysis from the consignors might be permitted, but the presentation of such documents does not preclude any sampling that might be considered desirable. The issue of a certificate to distribute would generally involve an examination by a consultant in Britain, registered as competent in the analysis of medicated products and pharmaceuticals. Holders of the joint Pharmaceutical Society and Royal Institute of Chemistry Diploma in Pharmaceutical Analysis are considered to satisfy this requirement.

Dispensed products. The present sampling of dispensed medicines under the National Health Service Acts is felt to be inadequate both in scope and manner. All dispensaries, whether under medical, pharmaceutical, dental or veterinary direction, should be subject to some form of control. The techniques of sampling might usefully form the basis of discussions with representatives of the professions concerned. It is proposed that the inspector be authorized to take as a sample any medicine or form of treatment, including proprietary preparations, awaiting collection for a patient (human or animal). It is implicit in this scheme that the inspector be provided with a copy of the relevant prescription. Quantities, for example, of tablets, supplied against a prescription could be checked on the spot by the inspector.

Retailers (*pharmacies, listed sellers, drug stores and retail suppliers of medicinal products*). It is expected that, as at present under the Food and Drugs Act, most samples will continue to be taken from retail establishments. It would be convenient to use the proposed scheme to exercise enforcement of Section 2 of the Pharmacy and Medicines Act, 1944, or the appropriate section of a new Consolidated Drugs Act. Pharmacists, by virtue of their professional training, will have knowledge of drug deterioration, but other retailers, having little or no experience of the problems, can unwittingly subject medicated products to storage and exposure conditions that are quite unsuitable; the use of batch identification codes is important in tracing any errors. A special example of unsatisfactory storage is the vending machine which may be exposed to a wide range of climatic conditions.

Sample Records

Bulk drugs and formulated products from U.K. manufacturers. A comprehensive quality control system can only be operated in a manufacturing unit where an efficient internal control system exists. While it is not part of the Committee's responsibility to define what system should be adopted, certain features are considered to be essential if the scheme is to work to the advantage of both the manufacturer and the public. For example, adequate specifications and control methods for both raw materials and finished products are fundamental. Manufacturers should investigate the stability of their products, and keep adequate records available for inspection; inspectors must have power to examine such records. As an interim measure only—and for such time as may be determined by the Controlling Authority—there may be some relaxation in respect of stability records, but manufacturers are urged to take serious note of the recommendation.

Supplies from importers. In the absence of satisfactory technical information submitted by the consignors or by the consignee's consultant analyst imports need to be sampled. Information will be required on: (*a*) the raw materials used; (*b*) specifications and control methods for the formulated products; (*c*) stability.

Reimbursement for samples taken. A scheme will have to be developed whereby reimbursement can be made for samples taken for examination.

ADMINISTRATION

The Committee does not propose to specify the form of the Controlling Authority, which would undoubtedly have wider responsibilities than quality control. While the Minister of Health may have governmental responsibility, the executive functions should be carried out by an independent body having the necessary legal powers. This body should be given the entire responsibility for the quality control of drugs.

Executive Organization

In the opinion of the Committee, the Pharmaceutical Society of Great Britain would be an appropriate 'Executive Organization'. The Society already has enforcement duties under existing Pharmacy Acts and its inspectors have considerable experience of conditions in retail pharmacy.

Advisory Committee

An advisory Committee—working in a voluntary capacity and including experienced representatives of the pharmaceutical industry—should be instituted to make recommendations on 'special cases' that may arise during the operation of any quality control programme, to advise on matters concerned with premises, registration, the issue of licences, etc., and to advise on general policy.

Directorate

To achieve effective quality control, a 'Directorate of Drug Testing' should be established. The Directorate would have the necessary powers of entry, inspection and sampling, and its own laboratory facilities. The director-in-charge, who should have appropriate technical qualifications, would be required to administer the scheme as a whole, and would be concerned with the day-to-day administration, inspection and sampling and with the analytical services. He should be directly responsible to the Executive Organization for all the activities of his department. The activities of inspectors and analysts involved in the control programme should be the responsibility of the director.

Inspectors

Inspectors should preferably hold a pharmaceutical qualification, but this would not preclude the appointment of other suitably qualified persons for specialist duties.

Qualifications. Inspectors must be trained in the techniques of sampling. Practical experience of manufacturing processes would be an advantage, as this would enable inspectors to act in an advisory capacity in matters related to drug control.

Functions of inspectors. The functions of inspectors will include: (*a*) inspection of premises of organizations seeking registration; (*b*) inspection on a routine basis of factories, warehouses, wholesalers' storerooms, hospital manufacturing and storage areas, dispensaries (medical, pharmaceutical, dental and veterinary), drug retailers' premises, clinics; (*c*) routine examination of control records of manufacturers; (*d*) routine examination of data sheets on importations; (*e*) the taking of samples and carrying out of local checks.

Manufacturers' analysts as inspectors. In other contexts manufacturers' analysts, under the supervision of the official inspectors, have been appointed as inspectors of their own organizations. In the proposed scheme this principle merits consideration.

Laboratory Services

A central laboratory will be required to carry out the analysis of samples submitted by the inspectors. Regional laboratories which will handle routine work may be needed since uniformity of interpretation of analytical results and of control is essential; the regional laboratories must be placed under the authority of the Central Laboratory. As an interim measure, until the establishment is at the requisite level, use of other laboratories, for example, those of public analysts and analysts holding appointments under the National Health Service Acts, might be considered. The authority of the director will, however, be paramount even where public analysts, who may be called on to sample over-the-counter sales, are concerned. The Laboratory of the Government Chemist should be used as a reference laboratory in cases of dispute.

Staffing (*personnel*). It is vital to the whole programme of a quality control scheme to establish confidence in the control exercised by the Central Laboratory. For this reason the staff must be of the highest calibre since it will be called on to conduct intricate analytical procedures and to undertake such analytical research as may be necessary to resolve problems. The senior members of the staff will be expected to advise the director on scientific and technical matters relating to the scheme. They would further be expected to participate on professional committees and collaborate on investigational work, possibly at international level.

Notes: (1) Since the testing of dressings requires special techniques, use should be made of established organizations, for example, the Manchester Chamber of Commerce Testing House and Laboratory. (2) Specialized testing of materials by bioassay techniques will involve the co-operation of established organizations capable of making such tests.

LEGISLATION

It is not the purpose of this Committee to indicate in detail what legislation is involved, but it directs attention to the following matters. Consolidating legislation would have to be introduced to correlate and extend the existing legislation under the Pharmacy and Poisons Act, 1933, the Food and Drugs Act, 1955, the National Health Service Acts, the Pharmacy Act, 1954, and to provide the powers necessary to permit the Executive Organization to conduct its affairs in an efficient and responsible manner.

Right of entry and inspection. The inspectors must be given the necessary powers to carry out their duties properly both as regards sampling and the inspection of premises and records.

Test results. A procedure must be developed whereby information on the results of the tests are transmitted to the source from which the sample was obtained.

Sanctions. In addition to the usual legal penalties the following sanctions might be applied: (*a*) withdrawal of licence; (*b*) removal of name from approved list of supervisory staff; (*c*) stock recall, impounding or destruction.

Appeals. There must be included some means of appeal against decisions of the inspectors or the director.

FINANCIAL

Whereas a detailed consideration of the financial aspects of the scheme is beyond the terms of reference of the Committee, attention is directed to the following points:

Expenditure. (1) Administrative expense of Executive Organization. (2) Administrative expense of Directorate and Inspectorate, including laboratory services. (3) Fees to outside analysts (for example, analysts responsible for bio-assays, public analysts, National Health Service analysts, Manchester Chamber of Commerce Testing House).

Income. (1) From registration and licensing fees (except dispensing areas). (2) From the Treasury.

INTERPRETATION

A drug (or pharmaceutical preparation) is any chemical or natural product or mixture of substances, including natural products, sold, offered for sale or represented for use in: (*a*) the diagnosis, treatment, mitigation or prevention of disease, abnormal physical state or the symptoms thereof in man or animal; (*b*) restoring, correcting or modifying organic functions in man or animal.

Drug in bulk. A chemical or natural product stored in bulk quantity intended directly for use in the manufacture of medicinal products.

Formulated product. A drug or mixture of drugs suitably prepared for administration as a medicine. A single chemical substance in small quantity, pre-packed for distribution.

Pharmaceutical specialty. A simple or compound drug ready for use, available under a special trade designation or in some characteristic form and containing one or more drugs which may or may not have official (that is, B.P., B.P.C., B.Vet.C.) recognition.

Proprietary preparation. A pharmaceutical specialty.

Surgical dressings, surgical sutures. Materials for application to wounds or lesions for therapeutic use or for their protection.

Dispensed medicine. Medicine dispensed for an individual patient in accordance with a prescription.

Medicated cosmetic or toilet article. A toilet article for external use on any part of the body, whether in liquid, solid or any other form and medicated so as to bring it within the requirements of the Pharmacy and Medicines Act, 1941.

THE SCIENCE COMMITTEE (PHARMACEUTICAL ANALYSIS)

The Science Committee (Pharmaceutical Analysis) of the Department of Pharmaceutical Sciences consists of: Dr. D. C. Garratt (chairman), Mr. J. Allen, Dr. A. L. Glenn, Mr. C. A. Johnson, Mr. E. I. Johnson, Dr. R. F. Milton, Dr. H. D. C. Rapson, Mr. S. G. E. Stevens and Mr. G. Sykes. Not all members are pharmacists, but all in their day-to-day activities are intimately concerned with the quality of pharmaceutical materials; some have had experience of drug testing under the present restricted schemes.

THE FISHERY LIMITS BILL

THE Fishery Limits Bill, which received its second reading in the House of Commons on June 15, establishes the fishery régime in British waters for which the Fisheries Convention resulting from the fisheries conference some months ago provides. As the Minister of Agriculture, Fisheries and Food, Mr. C. Soames, explained in moving the second reading, the Convention, which has since been signed by twelve countries including the United Kingdom, allows the coastal State a twelve-mile fishery zone measured from base-lines, and within this zone the State has power to regulate the fisheries. In the inner six miles the fishing is reserved for the fishermen of the coastal State, subject to a short transitional period for foreign fishermen who have traditionally fished within it. In the outer six miles the fishing is in principle reserved for fishermen of the coastal State and other parties to the Convention who have habitually fished in that area. In this way such foreign fishermen will be restricted to the stocks and grounds which they have already fished.

Mr. Soames emphasized that while Britain had consistently favoured the doctrine of narrow limits, the Government had concluded that some extension of limits could no longer be denied to Britain's fishermen. The Government's sole motive had been to secure more scope for Britain's fishermen in Britain's coastal waters. As regards conservation, the Government considered that the proper way to conserve fish stocks was by international action equitable to all in the conservation commissions which had been set up and in whose work Britain played a leading part. Mr. Soames said that there were some two or three countries which were not parties to the Convention but had some interest in the fisheries around

Britain's coast, although the extent of that fishing was not very great and Britain would need to consider with them what their position should be. It was hoped that the new arrangements could be brought into full operation by September.

The kernel of the Bill was in Clause 1, which provided for the extension of Britain's limits and for her control of access by foreign fishermen to the fisheries within these limits. The Convention provided that to qualify for recognition to be able to continue fishing between six and twelve miles this foreign fishing must have been carried on habitually during the ten years up to and including 1962 and that it must not be directed in future towards new grounds or new stocks of fish. In drawing up the designation orders, Mr. Soames said that Britain would, of course, need to take account of the fact that fish move round and that many species are often found on the same ground, but we would be able to distinguish between herring fisheries, fisheries for white fish and shell fisheries. The power of designation was not limited to the vessels of countries which were party to the convention, and Britain's fishery agreement with Norway provided that if Britain established a fishery zone she would be prepared to make for Norwegian vessels arrangements corresponding to those which that agreement made for British vessels off Norway. The new base-lines which Britain was drawing were in conformity with the 1958 Geneva Convention and she would be able to close bays with straight lines up to 24 miles in length, whereas at present 10 miles are the maximum lengths for a bay closing line. Until the Bill came into full operation there would be a transitional period for traditional foreign fishing between three and six miles from base lines. This was dealt with in Clause 2.

The right to enforce conservation measures on British and foreign vessels was one to which Britain attached great importance, but it did not require new powers from the House. It was simply a question of adapting the powers which existed under present legislation to apply conservation regulations to British vessels. This was done in the first schedule to the Bill. Mr. Soames emphasized that Britain now had a modern instrument for promoting conservation through international co-operation in the North-East Atlantic Fisheries Commission of which all countries fishing in the north-east Atlantic without exception were members. It was the responsibility of this Commission to take all the measures that conservation demanded. At a meeting of the Commission in June on the initiative of Britain a special committee was set up which would be concerned with making collective arrangements for enforcing conservation measures on the high seas. This Committee would apply conservation measures to foreign vessels when they were fishing within Britain's own fishery limits as well as to British vessels. Mr. M. Noble expressed the hope that members of the North East Atlantic Fisheries Commission, which included Poland and other countries not signatories to the Convention, would be able to work together so that, while Britain could enforce within her twelve-mile limit the conservation measures which she thought right, these other countries would at the same time be able to work out conservation measures and internationally the same measures could be adopted and brought into force.

NUCLEAR POWER IN BRITAIN

In the debate in the House of Lords on June 10 on the White Paper, *The Second Nuclear Power Programme* (*Nature*, 202, 1247; 1964), Lord Coleraine was concerned with the reasons for Britain losing her commanding lead in this field to the United States, which he attributed to the organization of the nuclear power programme. This he thought was far less efficiently organized in Britain than in the United States and this was partly because each power station carried an enormous load of research and development charges. He was concerned that the ordering of an American reactor system would mean that American technology would dominate the nuclear industry in Britain and that in effect she was opting out of that industry. He urged that the Government should take a hard look at the organization of the nuclear programme and particularly at the position of the Central Electricity Generating Board. He thought it was the function of that Board to provide the consumer in Britain with adequate supplies of cheap electricity, but that this function could not conceivably be combined with pioneering a new, expensive and complex industry. He did not think that a healthy nuclear industry could survive simply on the basis of copying designs. He suggested that the Atomic Energy Authority should be responsible for development until the first commercial station was in operation and proved, and then sell it to the Central Electricity Generating Board at a price which would meet the subsidy requested by the chairman of that Board. This was the system adopted in Canada.

Lord Champion agreed that Britain did not have all the information which should be available when considering a matter of this immensity and importance. Moreover, she had not yet resolved the problem of the extent to which the Board and the Authority should bear the responsibility for research and development of civilian types of reactors and the legislation required to amend the Authority's statute. Nevertheless, he thought that *The Second Nuclear Power Programme* was right in its flexibility, but Viscount Caldecote thought that it was doubtful whether technical resources had been as well used as they could have been and that the responsibilities had not always been shared in the best way among industry, the Atomic Energy Authority and the Central Electricity Generating Board. He thought it essential to see that scarce national technical resources were utilized to the best advantage, electrical power supplied as economically as possible, that there was an active research and development programme and that an efficient industry should be allowed to make reasonable profits on the capital involved. The proper use of national resources, he pointed out, required a stable policy and that there should be no duplication between industry, the Authority and the Generating Board as well as a much better delineation of responsibility. A suitable administrative set-up in the Government was required to control the Generating Board, the Authority and research and development and production work as well as the share done in industry. Viscount Caldecote suggested that the research functions of the Authority should be left under the Ministry for Science and Education and the responsibility of the Authority for development and collaboration with industry in their field reviewed. He entirely agreed with Lord Champion that Britain could not reject a system which was clearly and obviously more economic because it had been designed in the United States and not in Britain, but it was all too clear that it was very easy to have too much competition in these difficult technological and rapidly advancing fields.

Lord Stonham reiterated that not sufficient information was generally available for a proper judgment and that Britain should not reject an American system purely on the grounds that it was American. Lord Wolverton referred to the higher efficiency of the new station at Bradwell in Essex which had a thermal efficiency of 26·5 per cent compared with 19 per cent at Berkeley, Gloucestershire. He thought much more basic research was required before Britain embarked on a larger programme than that announced by the Government.

Replying for the Government, Lord Derwent pointed out that the magnox system might still show advantages in some other countries and that Britain should not take too insular a view of these developments. The building and commissioning of the present stations had involved a great partnership between the Authority and the Generating Board as well as with the Consortia, the contracting firms and the inspectorate of nuclear installations. The Government was satisfied that there was effective collaboration between the Generating Board and the Atomic Energy Authority, and there was, and always had been, close organization between the Consortia and the various firms in the contracting industry and these bodies. He agreed that the suggestion for adoption of systems and arrangements similar to that used in Canada merited careful consideration.

THE MUSEUMS ASSOCIATION

THE seventieth annual conference of the Museums Association was held in Nottingham during July 13–17 under the presidency of Dr. D. John, director of the National Museum of Wales at Cardiff.

The proceedings opened in the spacious Great Hall in the Trent Building of the University with a welcome from the Lord Mayor of Nottingham. Dr. John in his presidential address outlined the financial difficulties which beset the Association and mentioned some of the proposed measures to be taken to remedy this state of affairs. He congratulated the Area Museum Councils on the work they had achieved in the early stages of their plan to regionalize museums. He also referred to the 1963 report of the Standing Commission and to the recommendations, some of which had not been implemented by H.M. Government. In conclusion, he considered that at the present time there was a greater consciousness concerning museums among the general public and that much is moving forward in the museum world.

The general theme of the conference was that of "Public Relations" and this was introduced by Mr. C. Mann (president of the Institute of Public Relations), who gave a stimulating address on the importance of the public. He considered that the value of a work of art is in proportion to the number of people who see it, and for this reason museums should make every endeavour to attract the public to their galleries. A genuine belief that the public really matters was a curatorial necessity and he urged his audience to make more use of exciting entrance features, friendly and helpful attendants, and the creation of an atmosphere of goodwill.

Mr. C. Gibbs-Smith of the Victoria and Albert Museum followed with a paper on "The Fault . . . is . . . in Ourselves". He stated that good public relations meant plain good manners from the whole of the staff. He also felt that public relations should be the special duty of one member of staff who would be directly responsible to the director.

The theme was continued by Sir Frank Francis, director, British Museum, who said that museums though not in competition with themselves were certainly striving to gain customers in these days of more leisure and many interests. The aim of the curator should be to stimulate members of the public at all levels.

Mr. P. Johnstone (producer, B.B.C. Television) stressed the need for close co-operation between museums and the British Broadcasting Corporation. Both used visible communication methods and mutual help was essential. He advocated the setting apart of a special gallery in the museum for television work. Mr. I. Finlay, director of the Royal Scottish Museum, pertinently asked for what image was the museum striving and what public did we serve. A paper by the Rev. J. Jones-Davies describing the transformation of a small collection into a County Museum at Brecon closed the conference.

At the annual meeting, Mr. N. Cook, Guildhall Museum, London, was elected president for the year 1964–65 and an invitation to hold the annual meeting in Dublin in June 1965 was accepted with thanks.

Both the University and the City entertained the delegates at receptions, and during the meeting visits were arranged to the Newark and Derby Museums, Newstead Abbey, Boots Factory, Lincoln, Bakewell, Mansfield, Boston and other places.

F. S. WALLIS

PENDULAR MOISTURE IN PACKINGS OF EQUAL SPHERES

By PROF. COLIN C. HARRIS and DR. NORMAN R. MORROW
Henry Krumb School of Mines, Columbia University, New York

EXPERIMENTAL relationships between capillary pressure, P, and saturation, s_w, often feature an 'irreducible' fluid content shown in Fig. 1 as the saturation s_w^*. In a random packing of equal spheres of radius R, the pendular rings found at the minimum saturation are not in equilibrium with each other and cover a distribution of sizes[1]. Values of PR/γ calculated from the tables given by Fisher[2] fall largely in the range 3–11 which is also the range of PR/γ over which random packings of equal-sized hydrophilic spheres desaturate (Fig. 1, curve R_0), γ being the air-water interfacial tension. Direct measurements of ring pressures by means of a micro capillary-probe showed that, for a given ring, the ring pressure is equal to the capillary pressure, P, at the time of formation, the error in measurement being not more than 5 per cent[3]. The ring pressure remains constant once the ring has formed, provided that mass transfer to or from the ring is negligible[3].

In the work recorded here, random packings of equal-sized chrome steel spheres were saturated with dilute acid and then the packing was drained in a fine-pored, fritted-glass Buchner filter to the irreducible saturation. After about 0·5 h, the spheres were clearly etched over the areas of contact with the retained fluid; this occurred as isolated or linked rings of fluid held around points of contact between the spheres. Circles, or for linked rings equivalent circles, were selected at random and from their diameter, L (inset in Fig. 1), the volume, V, and pressure deficiency of each ring were calculated[2]. The distribution of L was found for three sphere sizes (diameter, D = 3·18, 4·76, 6·35 mm) taking two samples of 125 circles for each size of spheres. The cumulative frequency distributions of L/D were all of similar shape and fell within 0·06 of each other on the L/D scale. Allowance for porosity by correlation according to hydraulic radius in place of D halved the separation of these curves.

The average ring volume, $\bar{V}$, was calculated excluding the rings held at points of contact between the spheres and the walls of the containing vessel. An average number of points of contact, $\bar{n}$, per sphere for the 6·35 mm spheres was obtained by counting. The results showed good agreement with the method of obtaining the average co-ordination number from the porosity of the packing[4], which was therefore used to obtain a value of $\bar{n}$ for the two smaller sizes of spheres. Average residual saturations (s_p^*) calculated from $\bar{n}$, $\bar{V}$, D, and the bed porosity were 4·5, 5·0 and 4·6 per cent for the three packings taken in ascending order of sphere sizes.

The presence of linked rings found for about 25 per cent of the total number counted, showed that not all the pores in the bed were empty; from Fig. 1 it appears that all pores having an entry pressure of greater than about 10·5 (for example, spaces surrounded by three or four spheres in mutual contact) remain full. This is because they become isolated[3] before their entry pressure is reached. Thus there is residual-pore moisture additional to that occurring as pendular rings. Rings which have calculated values of PR/γ considerably greater than 10·5 are probably of the type that can be seen at points of near contact between the spheres; these have volumes larger and pressure deficiencies smaller than the values calculated. These two observations partly explain why bed saturation on account of rings alone, calculated from $\bar{n}$ and $\bar{V}$, gave residual saturations ranging from 4·2 to 5·3 per cent compared with 6–7 per cent measured by air-drying. In cubic and rhombohedral packings, which have porosities of 47·64 and 25·95 per cent respectively, all residual bulk moisture will be held as completely formed pendular rings. If these are formed at the approximate theoretical entry values of PR/γ of 4·8 for cubic and 12·9 for rhombohedral packings[5], their respective residual saturations will be 4·2 and 5·5 per cent. These values, calculated for two extreme types of packing, are close to the range found for the random packings with measurement of ring volumes alone.

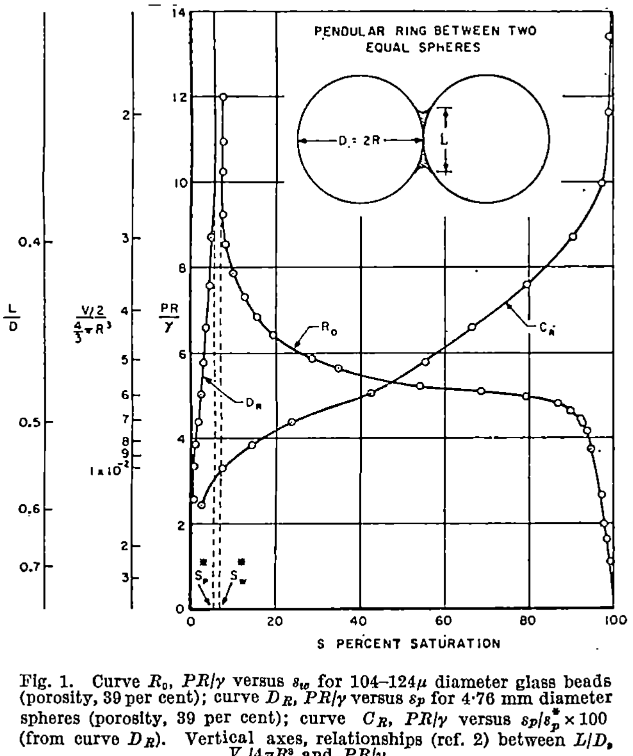

Fig. 1. Curve R_0, PR/γ versus s_w for 104–124μ diameter glass beads (porosity, 39 per cent); curve D_R, PR/γ versus s_p for 4·76 mm diameter spheres (porosity, 39 per cent); curve C_R, PR/γ versus $s_p/s_p^* \times 100$ (from curve D_R). Vertical axes, relationships (ref. 2) between L/D, $\frac{V}{2}\Big/\frac{4}{3}\pi R^3$ and PR/γ

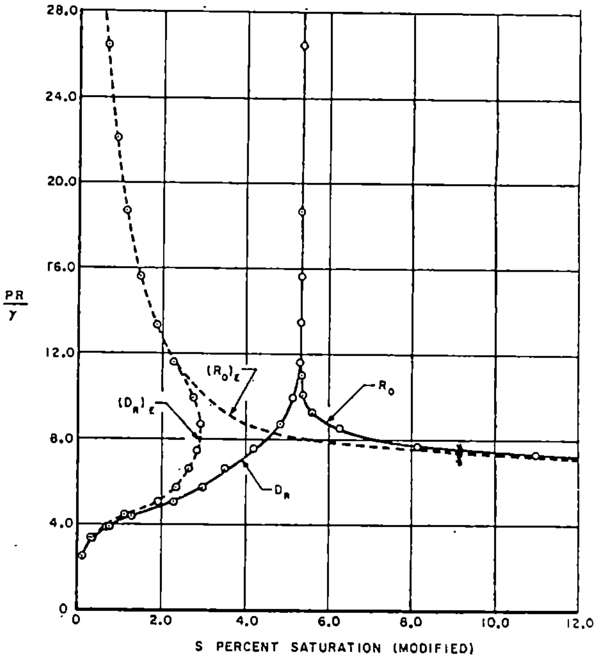

Fig. 2. Curve R_0, PR/γ versus s_w for 104–124μ diameter glass beads (porosity, 39 per cent); curve D_R, PR/γ versus s_p for 4·76 mm diameter spheres (porosity, 39 per cent); curve $(D_R)_E$ PR/γ versus s_p with pendular rings at equilibrium; curve $(R_0)_E$, PR/γ versus s_w with pendular rings at equilibrium

An approximately constant residual saturation of about 6–8 per cent is frequently reported for random packings of close-sized spheres provided that the ratio of gravitational to capillary forces is small[6]. For geometrically similar packings, the processes of desaturation and pendular ring formation maintain similarity in PR/γ; it is therefore to be expected that residual saturation is independent of sphere size. The effect of changing bed porosity is less predictable, mainly because it is not known how the amount of residual-pore moisture will vary. An increase in porosity results in fewer points of contact, but the corresponding pressure deficiency decrease for drainage causes an increase in the individual ring volumes. The approximate self-compensation of these two effects is illustrated by the closeness of the theoretical residual saturations calculated for cubic and rhombohedral packings.

In experiments with cubic packings of 6·35 mm spheres which were drained in a few seconds, it was observed that the ratio (> 1) of the size of rings held in the horizontal plane to those in the vertical decreased with increasing rate of drainage. While this effect can be eliminated by increasing the time of drainage the mechanism of ring formation is irreversible and involves as yet undetermined local pressure variations within the bed no matter how slowly the bed is drained. However, from the direct and circumstantial evidence so far available, it is believed that taking the ring pressure as the capillary pressure at the time of ring formation is a good working approximation for most of the rings and will for the present be assumed to hold for all isolated bulk moisture.

From this assumption, the accumulating quantity of moisture isolated during drainage as pendular rings is shown in Fig. 1 both as a percentage s_p of the total void space (curve D_R) and also as a percentage of their total maximum volume (curve C_R).

The relationship obtained if the pendular rings were given sufficient time to reach equilibrium with the capillary pressure, P, can be calculated by setting all formed rings (that is, those which have pressures less than or equal to the given value of P) at the ring volume corresponding to the pressure P. The curve so obtained (Fig. 2 curve $(D_R)_E$) passes through a maximum pendular saturation and then approaches the zero saturation axis asymptotically. A corresponding correction of this nature is required in order to obtain the form of truly time independent capillary pressure curves. The experimental time required to obtain such curves may be prohibitive. The change in the curve R_0 due to equilibration of the pendular rings is shown as the curve $(R_0)_E$. In order to illustrate the nature of the relationship between the two curves D_R and R_0 and their derived equilibrium relationships, residual-pore moisture has been omitted and the saturations employed have been calculated from the data shown in Fig. 1 with pore volume redefined as the sum of the moisture removed by suction and that calculated to be retained as pendular rings so that $s_p^* = s_w^*$.

The experimental curve D_R belongs to a postulated family of curves[3] relating the amount of moisture isolated as discrete quantities to the capillary pressure. This family and another for the isolated non-wetting phase are complementary to the well-known capillary pressure–saturation relationships[5].

INVESTIGATION OF NUCLEAR WEAPON DEBRIS WITH X-RAY MICROANALYSER

By J. SISEFSKY

Research Institute of National Defence, Stockholm

FROM 1958, investigations of the radioactive nuclear debris particles have been made in this laboratory. An autoradiographic technique has been worked out which allows identification and microscopic examination of the debris particles among all air-borne dust particles[1,2]. It was found that the particle activity is roughly proportional to its volume and that the strongest particles found, with an activity of the magnitude 10^4 d.p.m. β at an age of a few weeks, have diameters $\sim 3{\cdot}5$–5 μm. A rough estimate of the fission product content of such a particle clearly indicates that most of the particle mass must consist of some other material even if the greatest reasonable limits of uncertainty are taken into consideration.

As the X-ray microanalyser[3] is able to examine specimens of the size magnitude of μm, such an analysis could help to solve the problem of the composition of the debris particles.

High-altitude and ground–air samples from different parts of Sweden are continuously collected and autoradiographed on X-ray film. Large spots on the films indicate strong and thus[4] large particles. During the U.S.S.R. bomb test series, September–December 1961, particles of sufficient size mostly occurred in the ground–air samples. This has usually been the case. About 700 samples from a total of 1·2 kilotons of air were examined and some twenty large particles found.

As it is necessary to place the particles in the very surface layer of the preparate, the method of preparation in refs. 1, 2 and 4, therefore, was modified in the following way. With the help of the autoradiograms, small filter-pieces containing the interesting particles were punched out. The filter pieces were stirred in a viscous gelatin solution until a homogeneous suspension was obtained. The suspension was diluted and spread over a ~ 300 cm² glass plate and dried. The position of the particles was indicated by a new autoradiogram and the corresponding gelatin-layer pieces were punched out. In this way the active particles were freed from most of the accompanying dust.

The pieces of gelatin were dissolved in a few drops of water and the solution mixed with some ml. of Ilford nuclear emulsion in gel form type *G* 5 (electron-sensitive). The emulsion was cast as thinly as possible on a glass plate which was covered with a celluloid film, and allowed to dry to a ~ 10-μm thick layer. The plate was exposed for a week and developed in Ilford 'Ilfex' developer (5 min). The image was bleached away in a solution of 4 g potassium permanganate and 5 ml. sulphuric acid/l. (5 min). The stain obtained from the above bath was dissolved in a solution of ~ 50 g potassium pyrosulphite/l.; the image zones were finally cleared in a solution of 3 parts of acid-fast-fixing bath in 4 parts of glycerole (cf. ref. 2). The particles were thus indicated by being situated in the centres of clear circular zones against the, in course of time, more and more black emulsion. Care was taken to ensure that the photographic chemicals had no dissolving effect on the particles, and that they did not dissolve appreciable amounts of activity from them.

A first attempt to analyse the particles *in situ* was not successful as the electron beam caused local heating which was not led away by the glass and thus melted the gelatin and made the particle move away from the beam. Therefore, a ~ 1-mm² piece of the celluloid film with the emulsion containing the particle was cut away from the glass plate and placed upside-down on a polished copper plate. The celluloid was removed with acetone, leaving the particle in its gelatin film in a better position nearer the surface (as the particle sank to the bottom of the emulsion layer before it solidified). Still, the preparation was somewhat unsatisfactory; the gelatin persisted in making some small movements in the electron beam, and the covering gelatin, although very thin, absorbed some of the X-ray radiation, but the analysis this time could be performed at least semi-quantitatively.

The analysis was performed at the Swedish Institute for Metal Research, Drottning Kristinas väg 48, Stockholm. The results are shown in Table 1.

No element above $Z = 12$ (magnesium) not mentioned can be present to a content higher than ~ 2 per cent.

The results are in agreement with Rajewsky's examination of a 4-μ nuclear debris particle where iron and aluminium or silicon were found[5].

Mamuro and Fujita[6] report (for 7–14-μm particles) iron, aluminium and sometimes traces of silicon, although they find that the light-coloured particles have a high aluminium and a low iron content, and vice versa for the dark-coloured ones.

Calculation of the content of fission products causes some trouble, first, because the age of the particles, when measured, could be anything between 100 and 160 days, and secondly, because the composition of fission products is not the normal one, but is considerably altered by fractionation phenomena[7]. The particles were, however, individually measured in a low-background β-counter and, if strong enough, in a γ-counter, February 8–9, 1962 (at an age of 100–160 days). The two strongest particles (Nos. 6 and 11, Table 1) were also individually γ-spectrographed as well as all the particles together. The spectrograms show that 96 per cent of the γ-activity emanates from zirconium–niobium 95 and 4 per cent from other

γ-emitting nuclides, mainly cerium-144. A normal mixture of fission products of the age of 100 and 160 days gives respectively 63·6 and 94·5 per cent zirconium–niobium 95 γ-activity[8].

The ratio of β-counts to γ-counts did not vary much from ~ 2. Thus γ-activity of the particles too weak to measure was estimated to one-half of the β-activity. Considering the conditions above and previous experiences from large particles[7], it seems reasonable to assume a fission-product content corresponding to $\sim$ one-quarter of the calculated Zr–Nb content and an age of $\sim$ 160 days. In Table 1 the lower limits given correspond to an age of 100 days and a zirconium–niobium 95 enrichment by a factor of 4. This limit cannot be valid for the strongest particles, as it would need an unreasonable zirconium–niobium enrichment of a factor 12 to be consistent with the γ-spectra. The higher limits correspond to an age of 160 days and a zirconium–niobium 95 enrichment by a factor of 2 (ref. 7). The density of large nuclear-debris particles has been found to exceed 4 g/cm^3 by centrifugating a suspension of the particles in thallium–formiato–malonate. No heavier liquid is available except mercury (d = 13·6). It is reasonable to assume that the particles consist of oxides of the elements found and thus a density of 5 g/cm^3 may be correct within 20 per cent.

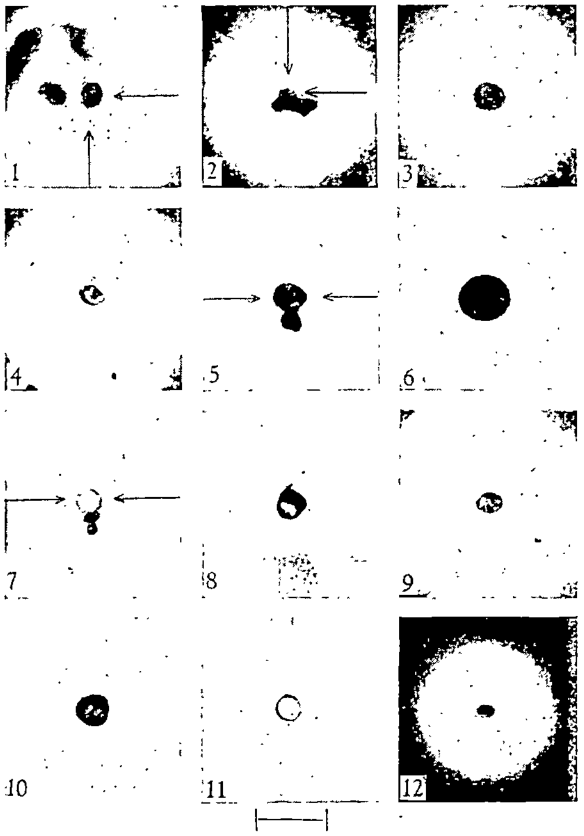

Fig. 1. Particles mentioned in Table 1

Assuming a fission efficiency in the vicinity of 20 per cent, the uranium content should be four times the fission content; thus 0·2–2 per cent by weight, which is consistent with the fact that uranium is barely detectable.

The low content of radioactive material in the particles is characteristic. A lot of nuclear debris samples (mostly the U.S.S.R. from 1958 (ref. 4) and 1961–62 (ref. 9)) with thousands of particles have been examined for correlation between particle size and activity. They give mostly about the same ratios of particle activity to particle volume as the above particles, thus indicating that only a small fraction of the particle mass consists of fission products.

The lead content can be explained by the use of lead in the tamper of the bomb[10].

It seems manifest that, although colourless particles as an average have a higher specific activity than red ones (100 × oil imm. obj. apert. 1·32) (ref. 11), the differences in colour do not indicate considerable differences in composition. The colourless particles especially do not lack iron (cf. ref. 6). Minerals with high content of iron are usually dark-coloured (hæmatite, hercynite, pleonaste, etc.).

The composition of the particles is peculiar. If the inactive material in the bomb is looked on as containment (bomb shell, construction material, the final rocket step) the ratio of containment to fissionable material seems remarkably great, apart from the case of tower shots. However, most of the U.S.S.R. shots at Novaya Zemlja occurred over the sea several miles from the west coast of the islands, and in most cases probably not below heights of $\sim$ 200 m (ref. 12). Thus, tower shots are likely to be excluded. Even if the iron is supposed to be the debris from containment, there should have been analysable amounts of alloying elements (such as manganese, chromium and perhaps titanium from rocket heads). The results of the analysis seem to indicate that most of the matter in the bomb debris particles does not emanate from the bomb itself, but from matter accidentally present in the air-volume occupied by the fire-ball. This could be particles from volcanic activity, meteorite particles, dust transported from the surface of the Earth up to the height of the nuclear blast (up to 3,600 m) (refs. 12, 13).

The apparatus used for β measurements was a 2·5-cm diameter, 7 mg/cm^2 end-window Geiger–Müller tube (General Electric *GM 4LB*) shielded with lead and an anti-coincidence arrangement, giving an efficiency of ~ 25 per cent for point-geometry, high-energy β-samples and 0·7 d.p.m. background counting. For γ-measurements: a 1·25 in. × 1 in. sodium iodide crystal, shielded by 10 cm lead, giving an efficiency for zirconium–niobium 95 (~ 0·75 MeV) of 4·8 per cent (measured with a point-geometry sample of known strength) and a background of ~ 40 c.p.m.

APPARENT ANISOTROPY FIELD OF CONTINUOUS MAGNETIC FILMS SUBJECTED TO INHOMOGENEOUS DRIVE FIELDS

By J. G. EDWARDS

General Electric Co., Ltd., Central Research Laboratories, Hirst Research Centre, Wembley

THIN magnetic films deposited in a vacuum on to smooth substrates under the correct conditions[1] exhibit uniaxial anisotropy; that is, in the absence of a magnetic field the magnetization is stable in either of the two directions along an 'easy' axis in the plane of the film. If a homogeneous field is applied to the whole area of a film, along a 'hard' direction (perpendicular to the easy axis), the magnetization rotates towards this hard direction. The magnitude of the uniform field required to rotate the magnetization just into the hard direction against the internal anisotropy torque is known as the anisotropy field and depends on the deposition conditions and the composition of the film. One of the puzzling features of the properties of continuous magnetic films is that when the hard direction field is applied inhomogeneously by a strip conductor, the field required to rotate the film can be several times larger than the anisotropy field of the film when subjected to homogeneous fields.

The conditions affecting the value of the apparent anisotropy field were extensively investigated by Leaver and Prutton for many strip conductor widths, film thicknesses and anisotropy field values[2,3]. They showed that the excess of the apparent anisotropy field over the value measured using homogeneous fields was qualitatively consistent with an effect of demagnetizing fields: when the strip of film is activated by the passage of a current down the drive conductor, magnetic poles appear down the edges of the strip and produce a field within the strip which opposes the field applied by the strip conductor. Theoretically, the field required to rotate the film into the hard direction is increased by an amount proportional to the film thickness and inversely proportional to the mean separation of the band of poles. The measured increase, however, is far more than would be expected if the bands of poles were beneath the edges of the strip conductor. It might then be assumed that, for the case measured by Leaver and Prutton, the bands of poles were not beneath the edges of the strip but nearer the centre, giving an increased demagnetizing field. However, our experiments, using continuous films, show that in cases where the whole film beneath the strip conductor is known to be saturated (so that the bands of poles must be beneath or beyond the edges) the apparent anisotropy field is still far in excess of any value that could be accounted for by demagnetizing fields.

Explanation of apparent anisotropy field by propagation of magnetization changes in a continuous film. An alternative explanation for the anomalously high values of effective anisotropy field arose when it was found that, with a continuous film, magnetization changes could occur well beyond the edges of the strip conductor although the field was applied directly only beneath the strip[4]. This propagation is probably due to magnetostatic coupling between neighbouring regions of film, but the precise mechanism causing the propagation does not affect the present explanation. It was realized that, because the propagation occurred, larger fields had to be applied to the film to rotate the magnetization of the central strip against the internal anisotropy torque of the outer areas. This can be shown by considering a strip of film of length l beneath the drive conductor of width w. If we assume that all the magnetization within this strip rotates coherently through an angle θ_0 under the influence of the applied field, then the torque exerted on this strip of film by the field, H, is:

$$T = MflwH \cos \theta_0 \qquad (1)$$

where M is the magnetic moment per unit volume and f the thickness of the film. Now the torque which must be exerted on a segmental strip of the film parallel to the conductor and of width dx in order to maintain a deflexion θ is:

$$dT = MflH_K \sin \theta \cos \theta \, dx \qquad (2)$$

where H_K is the anisotropy field of the film. To avoid repetition of the analysis we shall anticipate the experimental result and assume that the magnetization deflexion in a segment away from the strip conductor (where no field is applied directly) is such that the hard-axis component of the magnetization decays exponentially with distance, x, away from the edge of the strip conductor:

$$\sin \theta = \exp(-x/p) \sin \theta_0 \qquad (3)$$

where p is the propagation constant. Now the total torque that is required to maintain a magnetization deflexion of θ_0 beneath the drive strip and a deflexion given by equation (3) on each side of it is obtained by integrating equation (2)*. For small deflexions, $\cos \theta \simeq \theta_0 \simeq 1$ and:

$$T = \int_{-\infty}^{\infty} MflH_K \sin \theta \cos \theta \, dx = MflH_K \sin \theta_0 \cos \theta_0 (w + 2p) \qquad (4)$$

---

* Note that there can be no net torque on the film due to any fields caused by the pole distribution. Any torque on the film at one point due to a pole at another must be exactly balanced by an opposite torque at the second point.

Because torque is not a localized quantity, we can equate the total torque required to maintain the known magnetization distribution (equation 4) and the torque produced by the applied field (equation 1), giving:

$$wH = H_K \sin \theta_0 \, (w + 2p) \tag{5}$$

For the case of a homogeneous applied field (w very large), even for large deflexions, we have:

$$H = H_K \sin \theta_0 \tag{6}$$

Equation (6) expresses the well-known line hysteresis loop for fields applied in the hard direction: when $H = H_K$ the film reaches the hard direction and the anisotropy field can be obtained from the initial slope of the plot of hard direction magnetization against hard direction field. Rearranging equation (5), we can obtain the analogous equation for a field applied inhomogeneously:

$$H = H_K(1 + 2p/w) \sin \theta_0 \tag{7}$$

Measuring the incremental slope will give the apparent anisotropy field, $H_K(1 + 2p/w)$. This is not quite the same as the field required to rotate the central strip into the hard direction ($\theta_0 = 90°$) because of the approximation that $\cos \theta$ everywhere equals $\cos \theta_0$ which will not be valid for points remote from the drive strip when θ_0 is large. In any event, however large the applied field, the strip of film beneath the drive strip could never quite reach the hard direction (when the applied torque would be zero and no torque would be required by this strip of film) because a torque is still required to deflect the magnetization of the remote regions of film.

Apparatus and techniques. The arrangement used to measure the propagation of magnetization changes is shown in Fig. 1. The conductor pattern was photo-etched from 25μ copper sheet and insulated from the film and conducting substrate by 6μ 'Melinex'. By connecting various numbers of drive strips the drive-strip width could be varied between 0·5 and 3 mm. Pulses 100 ns long and having rise times of about 1 ns were obtained from a mercury wetted reed discharge line pulse generator and matched into the low-impedance drive strips through a 50 Ω matching resistor. Each drive strip was individually terminated and the current produced by the generator was established within 3 ns in the drive strips irrespective of the number used. Equal current sharing between the strips is ensured by earthing at the far end so that there is no potential on them after the first double transit time. All the matching and terminating resistors were screened by placing them in milled recesses in the base plate of the test jig. The common return wire for the sense wires was returned near to the sense wires themselves to reduce any E.M.F. due to eddy currents induced in the conducting base plate when the drive current flowed. Any transient capacitive E.M.F. produced in the sense wires beneath the drive strips was reduced by connecting the oscilloscope to the sense wires through a 'balun' transformer[5]. With this arrangement, only differences in potential of the sense and return wires are detected. When the drive pulse begins the magnetization of the film beneath a sense wire rotates through an angle θ towards the hard direction and the flux change produces a triangular pulsed E.M.F. of height V and base-length t, such that:

$$Vt/2 = 4\pi \, Mfl \sin \theta \tag{8}$$

where l is the length of the sense wire. It was found that the value of t was about the same ($\sim$ 10 ns) for all the sense wires and so the E.M.F., V, can be used as a measure of the rotation, θ, of the film beneath the sense wire, once a slight correction for the differing lengths of the sense wires has been made. The signal/noise ratio depended on the film and the drive current but scarcely at all on the particular sense wire being used, the worst value being about four. The measurement of every point included the measurement and subtraction of the noise, the noise being the value obtained by locking the film with a large permanent magnet.

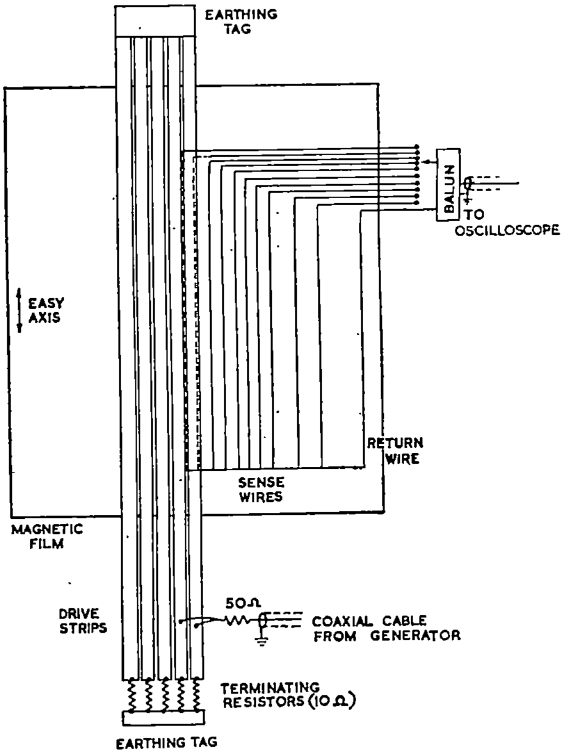

Fig. 1. Arrangement used to detect propagation of magnetization changes. The aluminium plate carrying the film fitted into a recess in the base plate, giving a continuous conducting plane. The drive strips were 0·5 mm wide separated by 0·1 mm gaps. The sense wires were 0·1 mm wide and spaced at distances of 5, 4, 3, 2·5, 2·0, 1·5, 1·0, 0·5, 0, −0·5 mm from the edge of the drive strips

The loop plotter used to measure the anisotropy field of the film under homogeneous applied field conditions produced results consistent to within about 10 per cent (this is the standard deviation of a series of measurements of the same film). The oscilloscope used to measure the drive currents could be read consistently to about 5 per cent and had a maximum sensitivity of 10 mV/cm with a rise time of 4 ns.

Experimental results. Curves were plotted of the outputs obtained from the various sense wires as a function of the drive current for various widths of drive strip and for films having a range of thicknesses and anisotropy fields. A typical result is shown in Fig. 2. It can be seen that the sense wire detecting the magnetization changes up the centre of the strip (curve 1) gives a curve with a linear initial portion flattening off as the film beneath it approaches saturation. This is in accordance with equations (7) and (8) which predict a linear increase in $\sin \theta$, and hence of V, with applied field. The rounding off of the corner, instead of a sharp bend as predicted by the equations, is probably due to dispersion in the anisotropy field of the film. The curve for the sense wire beneath the edge of the drive strip is almost identical to the curve for the wire in the centre, indicating that the magnetization changes are almost uniform in the strip of film directly beneath the drive conductor. The sense conductors (curves 3 and 4) away from the film show a reduced magnetization change increasing linearly with drive field up to about the field at which the central strip became saturated (about 24 oe) when the slope decreases. The finite slope of the second part of the curve was shown to be due to field spread from the strip conductor: this slope is approximately inversely proportional to the drive conductor width so that it is the current density which is important. As the drive current density increases, the region of uniform changes also increases, causing a corre-

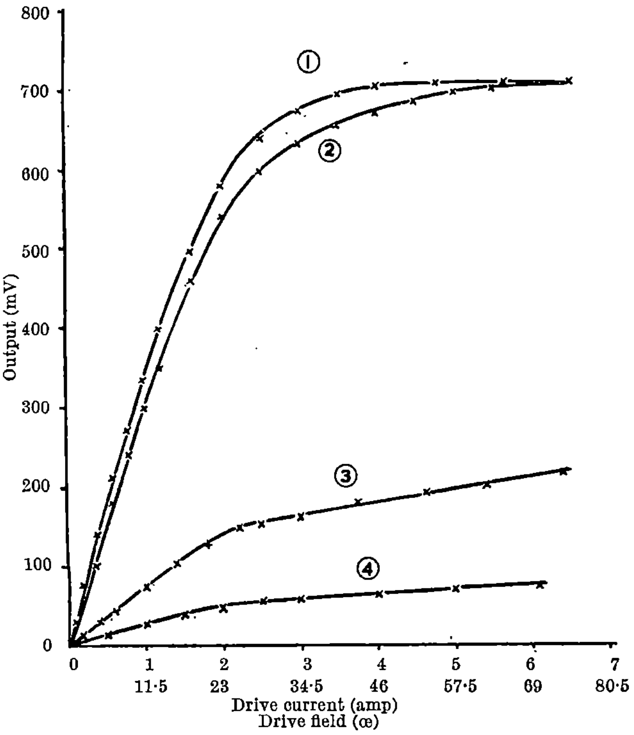

Fig. 2. Output from sense wires as a function of drive current and equivalent drive field. Drive strip width 1·1 mm, film: 2200 Å thick, H_K 8·7 œ. Sense wires: 1, at centre of strip; 2, at edge of strip; 3, 0·5 mm from edge of strip; 4, 1·0 mm from edge of strip

sponding outward shift in the magnetization distribution and giving a larger output from the sense wires. The apparent anisotropy field was measured from curves such as those in Fig. 2 by extrapolating the initial slope of curve 1 until it reached the peak output obtained at saturation. From the known relationship between drive conductor width, drive current and drive field the apparent anisotropy field can be found. Thus for the film of Fig. 2 the apparent anisotropy field was 24 ± 1 œ with a 1·1-mm wide drive conductor while the true anisotropy field measured on the loop plotter was only 8·7 ± 0·8 œ.

The distribution of magnetization changes in the film away from the drive conductor was found by measuring the output from each sense wire at a particular current below the knee of the curve. When the outputs were plotted on a logarithmic scale as a function of the position of the sense wire a straight line resulted, the slope of which appeared to be independent of both the drive field, if this was less than the apparent anisotropy field, and the width of the drive conductor. Since at any point the flux change due to the deflexion of the magnetization is proportional to the local resultant field, for this direction of measurement, it follows that this resultant field must fall off exponentially with distance from the edge of the drive conductor. The slope of the straight line provides a measure of the propagation constant, p, of equations (3) and (7). Measured values of p were between 0·3 and 1 mm. Since the curves of Fig. 2 are initially linear, the result that the propagation constant does not depend on the drive field is to be expected. The lack of dependence of the propagation constant on the drive-conductor width indicates only that the field at the film on one side of the drive conductor due to a line of poles on the other is too small to be of significance. From equation (7) we have the theoretical relationship between the apparent anisotropy field, H'_K, the true anisotropy field, H_K, the propagation constant, p, and the drive conductor width, w:

$$H'_K = H_K(1 + 2p/w) \qquad (9)$$

In Fig. 3 the values obtained by inserting the measured parameters into the right-hand side of equation (9) are plotted against the apparent anisotropy field measured directly for all the films and drive-conductor widths used. It can be seen that a reasonably good correlation is obtained, even although the films used were prepared under widely differing evaporation conditions and in three different plants. This suggests that the explanation of the increase in the apparent anisotropy field over the true value in terms of the propagation of magnetization changes is correct.

Cause of propagation. It was mentioned above that a possible cause of the propagation was magnetostatic coupling between neighbouring regions of film, but a further discussion of this is of interest. If the propagation did not occur, a line of poles would appear beneath the edge of the drive conductor and a field of the order of 10^4 œ would appear on either side of the line of poles. This field would tend to demagnetize the film beneath the drive conductor and tend to magnetize the film beyond the drive conductor, though producing no net torque on the film as a whole. Any magnetization changes produced by the hypothetical line of poles would broaden the line into a band and reduce the energy of the system. Now, the field produced by a line of poles is proportional to the thickness of the film and inversely proportional to the distance. The change of magnetization at any point in the film also depends on the relative magnitudes of the applied field and the anisotropy field. Thus it would be reasonable to suppose that the propagation constant would be greater for thicker films of lower anisotropy. Accordingly, an attempt was made to correlate the propagation constant with the film parameters. The propagation constant was found to have no distinct correlation with either the film thickness or the true anisotropy field, but there was a positive correlation with the ratio of film thickness to anisotropy field. The points obtained could be roughly enclosed in an ellipse with a ratio of major to minor axes of about three. This evidence alone cannot support the hypothesis of a linear relationship between the propagation distance and the ratio of film thickness to anisotropy field. We have as yet been unable to complete any rigorous theoretical calculation of the form of the magnetization distribution, as the integral equation describing

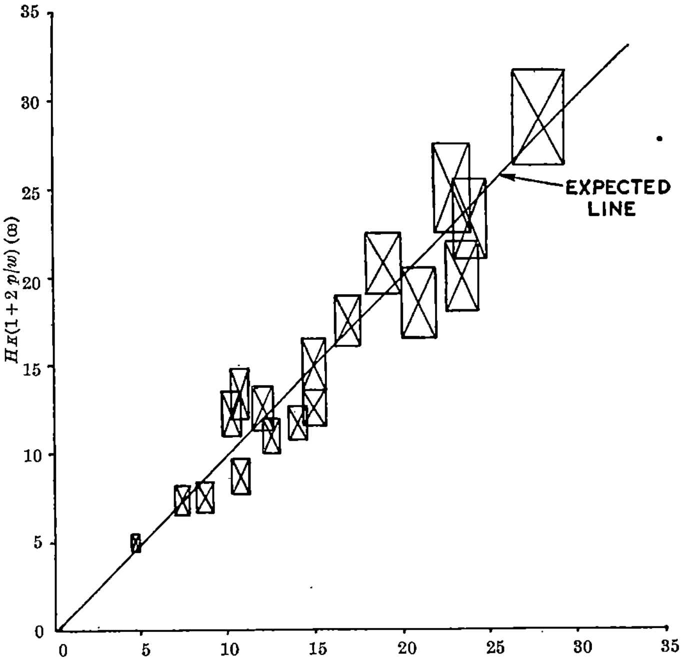

Fig. 3. Correlation between the apparent anisotropy field calculated from film parameters and the apparent anisotropy field measured directly. The points cover the ranges: true anisotropy field 3·4–10·0 œ; film thickness 700–4400 Å; drive conductor width 0·5–3·0 mm. The size of the points represents the probable random error

the equilibrium magnetization distribution requires the use of an analogue computer to obtain the solutions. An attempt to obtain an approximate solution using a digital computer was unsuccessful.

The possibility that the propagation might be due to exchange rather than magnetostatic coupling was investigated by removing a strip of film about 100 μ wide 0·8 mm from the edge of the drive conductor. The magnetization distribution was found to be unaffected by the break in the film. This appears to eliminate exchange coupling, which has a very short range and could not cross the break in the film. Magnetostatic coupling, on the other hand, would scarcely be affected, being a comparatively long-range force. If the propagation is due to magnetostatic coupling it would be expected that slight misorientation of the easy axis of the film would not affect the distribution of magnetization changes significantly. It was found that the outputs obtained from the sense wires were not affected significantly by misorientations up to 20°, larger misorientations giving a reduction in output. As might be expected from this result, there seemed to be no consistent dependence of the propagation on the angular dispersion of easy axes of the film.

Easy axis propagation. Propagation was also found to occur along the easy axis of the film when it was subjected to a hard direction bias field equal to the anisotropy field. Under these conditions the permeability along the easy direction is at a maximum, being in general about twice the normal permeability of the film in the hard direction[6]. It was found that the magnetization distribution created by the drive current applying an easy axis field was very similar to that created by the hard direction drive field: the magnetization change is nearly uniform beneath the strip conductor and falls off exponentially with distance away from the edge of the conductor. The easy axis propagation constant, p, was in general about 20 per cent less than the hard axis constant although the easy axis field required to produce a given flux change at the central sense wire was less than the hard axis field required to produce the same change (the permeability being more). There is no obvious reason why the hard and easy axis propagation constants should be similar, and the interpretation of this result must await the solutions of the relevant equation[7].

Conclusion. The increase of the apparent anisotropy field obtained with inhomogeneous applied drive fields over the true value found using homogeneous fields can be explained by the propagation of magnetization changes beyond the region of film subjected directly to the applied drive fields. The larger area of film influenced requires a correspondingly larger total torque to produce a given rotation in the region where the field is applied. The values of propagation constant found can predict the apparent value of anisotropy field to within the experimental error. The precise cause of the propagation does not affect this prediction, given the result that the magnetization changes decrease exponentially away from the edge of the drive conductor. It seems most probable that the propagation is due to magnetostatic coupling, especially since the expected dependence of the propagation distance on the ratio of film thickness to anisotropy field is confirmed experimentally. Any complete confirmation of this hypothesis must await the results of the calculations of propagation constant as a function of film parameters and comparison with the experimental results.

GRAININESS IN THE PHOTOGRAPHIC RECORDING OF ELECTRON MICROSCOPE IMAGES

By Dr. R. C. VALENTINE and N. G. WRIGLEY
National Institute for Medical Research, Mill Hill, London, N.W.7

GRAININESS can be seen in any over-enlarged photographic image. But since basically the image on the negative is simply an array of silver grains held in a thin layer of gelatin, the effect is often thought to have an obvious explanation. However, the silver grains themselves are seldom more than 1μ (10^{-4} cm) in diameter and in fine-grain material many may be beyond resolution with an ordinary microscope. So clearly graininess, which can often be seen in a ten-times enlargement, is not to be explained in a way that would make the silver grains analogous to the points of ink in a printed illustration. In fact, it results from the fluctuations in the numbers of grains in each just visible area, and the primary cause of these fluctuations does not lie in the photographic emulsion at all but in the radiation to which it has been exposed. Whatever its nature, this radiation arrives as quite independent particles in the form of quanta or electrons. A photographic negative may have been exposed to what is macroscopically a constant, uniform beam of radiation and, if the intensity is known, a simple calculation will give the mean number N of particles that fall on an area of given size in a stated length of time. But the arrival of the individual quanta or electrons is quite random, and the actual numbers that arrive from spot to spot and from moment to moment will not be constant but will fluctuate around the mean number N. Such random events conform to Poisson's law and the extent of the fluctuation is predictable; it will have a root-mean-square value of $\pm \sqrt{N}$. The fluctuation expressed as a fraction of the mean is thus $1/\sqrt{N}$. Where N is very large, $1/\sqrt{N}$ is insignificant and the radiation appears uniform and constant. But when small areas or short times are considered and N is consequently small, the fluctuations become very obvious; if, for example, N is only 100, the root-mean-square fluctuation becomes 10 per cent of the mean.

When the emulsion is exposed to an image instead of to a uniform beam of radiation, the smallest detail of given contrast that can be detected in the picture will clearly be limited by the graininess. The problem put in terms of simple information theory is that the signal (which here is the change in density on the negative caused by the object we want to detect) must be significantly larger than the noise (which is the random fluctuation in density in areas of the same size). In practice, unless the signal-to-noise ratio is greater than five, the object will not be detectable with certainty. The reason is that the amount of information conveyed from the object to the negative is not statistically significant and, since it is clear that no subsequent photographic manipulation when making

The figures in brackets under each developer give the dilution as parts of stock developer to parts of water. Development was at 21° C for 4 min in a dish with intermittent agitation. The developers were freshly made up according to the manufacturer's published formulæ.

As explained in the text, the figures give a rough idea of exposure time in seconds when the beam gives a well-lit fluorescent screen.

enlarged prints can ever add to this information, the object will be lost in graininess, however such prints are made.

In the same way the signal-to-noise ratio on the negative can never be better than the ratio in the optical image during the time of exposure; but it may be considerably worse. Such loss of information in the photographic recording of the image will occur when each photon or electron in the image does not contribute equally to the optical density of the negative. For example, if three-quarters of the photons in the optical image pass right through the photographic emulsion without being absorbed by a grain of silver halide, they obviously contribute nothing to the photographic image. The number of effective photons is thus reduced to a quarter and so the noise (which varies with the square root of the number) is doubled with no increase in signal. The non-linear response of photographic emulsions to light complicates the rigorous application of information theory, but Fellgett[1] has estimated that a 100-fold loss of signal-to-noise ratio occurs in forming the negative with even the best emulsions available to-day.

It is well known that the resolution obtained in electron microscope pictures of biological specimens falls disappointingly short of the 5 Å resolution which can now be demonstrated with suitable test objects. The electron contrast in the ultra-structure of biological materials is so low that details smaller than 20 Å are almost always lost in graininess. In part it is true that this graininess is not photographic but exists in the film used to support the specimen or in the stains used. But if the recording of the electron image on the photographic plate was anything like as inefficient as the recording of a light image, much relevant information might be present in the electron image but lost in the photographic processes. It would then be well worth looking for more efficient ways of recording the image.

The response of a photographic emulsion to the usual 40–100 kV electron beams used in microscopy differs from the response to light in being almost exactly linear over the whole useful working range[2]. The optical density on the plate (or film) after it has been processed is proportional to the number of electrons per unit area to which it was exposed. As a consequence, a straightforward measurement gives the loss of signal-to-noise that occurs in recording the electron-microscope image. A plate is exposed in the usual way in the electron microscope but without a specimen in place. It is easy to arrange that the beam on the plate is uniform. After being processed, the plate is scanned with a recording microdensitometer and, as the aperture of the densitometer is reduced, the random fluctuations due to graininess increase. For any selected aperture area A the trace can be used to calculate the root-mean-square fluctuation in density σ and also the mean density D of the plate. If the constant k is known that relates the optical density D to the number of electrons per unit area to which the emulsion was exposed (k being, in fact, a measure of the speed of the plate to electrons), then the mean number of electrons on an area A is given by $N = AD/k$. The ratio r of signal-to-noise in the photographic image to that in the electron image is $(\sigma/D)/(\sqrt{N}/N)$ and so $r = \sigma\sqrt{A}/Dk$. For a perfect recording of all the information in the electron image r would be unity, but since in practice some information must be lost in the photographic processes $r < 1$. For exposure to light it has already been mentioned that an estimate gives r as only 0·01.

A measurement of r for an electron micrograph requires in addition to the densitometer measurements a value for k. Since there are very few published measurements of the speeds of various emulsions to electrons[3,4] we measured k for a wide range of commonly used emulsions in various developers. Each plate was exposed in the electron microscope to a 60-kV beam for an appropriate time. The electron exposures given can be measured with a Faraday cage[3], but we found it as accurate and more convenient to make counts of electron tracks on nuclear track plates (Ilford *G*.5 and *L*.4 : 10μ thick emulsions) which had been given a known fraction of the exposure. The emulsions under test were processed in the usual way with 4-min development in an intermittently agitated dish and their optical densities measured with the Joyce–Loebl microdensitometer using a large aperture. The speeds of the various emulsions were thus determined and are given in Table 1 as the number of electrons per μ^2 ($= 10^{-8}$ cm^2) that give a specular density $D = 1$. This is a convenient way of expressing speed (though it should be noted that the figures give the reciprocal of k and that a high speed is shown by a low figure), for when the fluorescent viewing screen in the microscope is made just bright enough for the image to be seen clearly it will be receiving very approximately 1 electron/μ^2/sec. So the figures in Table 1 also indicate roughly the exposure time in seconds that each emulsion will require if exposed to the image at the same intensity that is used for direct examination on the screen.

Microdensitometer traces were then taken to obtain values for σ. The densitometer aperture A was chosen to

give a reasonable fluctuation in D (usually A was $50 \times 50\mu$ or $100 \times 100\mu$). The density of the plates was arranged to be close to $D = 1$. The value of r, the fractional loss of the signal-to-noise between the electron image and the photographic image, was then calculated for each emulsion from the equation given above, and the results are shown in Table 2. This clearly indicates that the photographic emulsion is an almost perfect recorder of the electron microscope image. Indeed, except for the very slowest plates, it is doubtful if in practice any of the figures would be significantly different from $r = 1$, and with several emulsions any loss of signal-to-noise was immeasurable. Thus photographic granularity in electron micrographs can be almost always equated with electron noise: so the faster the emulsion the more prominent graininess will become because for the same density the emulsion will have been exposed to fewer electrons.

If one assumes the normal contrast constants[2,5] for an electron microscope working at 60 kV with a 50μ objective aperture for various specimen weight densities ρ (approximately for most metals $\rho = 20$; for negative staining $\rho = 5$; for positive staining $\rho = 2$), then the minimum magnification of the image on the plate or film in the electron microscope to show specimen detail at any level of resolution distinctly above photographic grain can be calculated. We find approximately that the minimum magnification is given by $M = 10^8/(\rho x^2\sqrt{n})$ where x Å is the required resolution and n the number of electrons/μ^2 required by the emulsion for $D = 1$ as listed in Table 1. Obviously imperfections in the specimen or in the supporting film may in practice limit useful resolution to larger sizes than that given by this equation; on the other hand, apparent detail that is much smaller is likely to be photographic grain unless it has some regular feature (such as parallel lines in a crystal lattice) that aids recognition.

AN ELECTRODEPOSITION METHOD FOR THE PREPARATION OF ELECTRON MICROSCOPE SPECIMENS

By W. PARKER* and H. BAUMGARTNER
Institute of Chemistry, Reactor Centre, Seiberdorf, Austria

IN the course of some recent investigations[1-7] concerning the cathodic deposition of various elements in the chloride, nitrate or sulphate form from alcohol plating solutions, apparatus and procedure were developed whereby thin films produced in this manner could be prepared in a form suitable for examination in an electronmicroscope of the Siemens Elmiskop I type. While our own interests were mainly directed toward various chemical compounds of uranium, the success and simplicity of the method and application to other elements are obvious.

The electrodeposition cell shown in Fig. 1 is constructed in two parts, A and C, which can be screwed together. A plastic tube D is connected by means of a nozzle to section C of the cell, and is fed by a mercury bulb provided with a tap F and a metal seal for electrical connexion. The specimen grid holder (Fig. 2) consists of a stainless-steel disk C, 28 mm in diameter, with a recessed stainless-steel projection B. The specimen grid, after cleaning, is placed in recess A. The top section of the cell is removed and the specimen grid holder placed, as shown in Fig. 1 B, in the cell base C, and held in position by replacing the top section of the cell A. The cell is now ready for flooding with mercury. This is achieved by raising the mercury bulb until the stainless-steel disk is covered by mercury and final adjustment made by regulating the flow of air into the bulb with tap F. The mercury should just cover the top of the specimen grid.

In our particular case, stock solutions of uranyl nitrate, uranium chloride and uranium sulphate were prepared having a concentration of 1 mg/ml. in distilled water. The cell was filled with 15 ml. of isopropanol and 10 µl. of the stock solution in question added during the stirring of the solution with a platinum anode having the form of

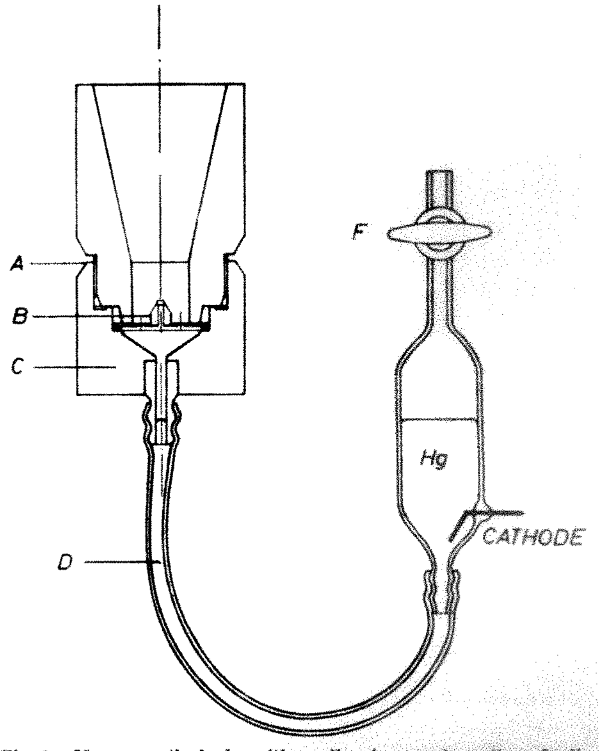

Fig. 1. Mercury cathode deposition cell. A, screw-in section of cell; B, specimen grid holder; C, base of cell; D, polyethylene tube; F, fine mercury-level adjustment tap

a flat spiral. Finally, 100 V d.c. was applied between the anode stirrer and mercury bulb. The distance between the anode and the mercury surface was adjusted for minimum current flow.

---

* Present address: Department of Physics, Chalmers University of Technology, Gothenburg, Sweden.

After the completion of a 2- or 3-min run the anode is withdrawn and the plating solution siphoned off. The level of the mercury is very carefully lowered to a point just below the specimen grid and then drained out completely from the cell. Part *A* of the cell is screwed off and the specimen grid holder removed. During the early phases of the work some trouble was caused by small quantities of mercury being trapped between the deposited film and the specimen grid. However, providing some care is taken in the cleaning of such grids, no undue difficulty should arise. We found that washing the platinum grids in concentrated nitric acid followed by alcohol was satisfactory for this purpose.

Figs. 3 and 4 are some of the results obtained from specimens prepared from uranyl nitrate plating solutions. In this case the deposited material proved to be uranium dioxide and not, as was originally thought to be the case, the same compound as that dissolved in the plating solution[1]. However, recent dissociation studies involving the labelling of magnesium sulphate with radiosulphur (sulphur-35), or $Mg^{35}SO_4$, have shown that under carefully controlled conditions magnesium sulphate is plated out as such at the cathode[7]. It has also been pointed out that this could be the case with the uranium salts, but that they are later converted to the dioxide caused by the heating of the electron beam. In order to test this possibility, labelling will also be applied to uranium sulphate.

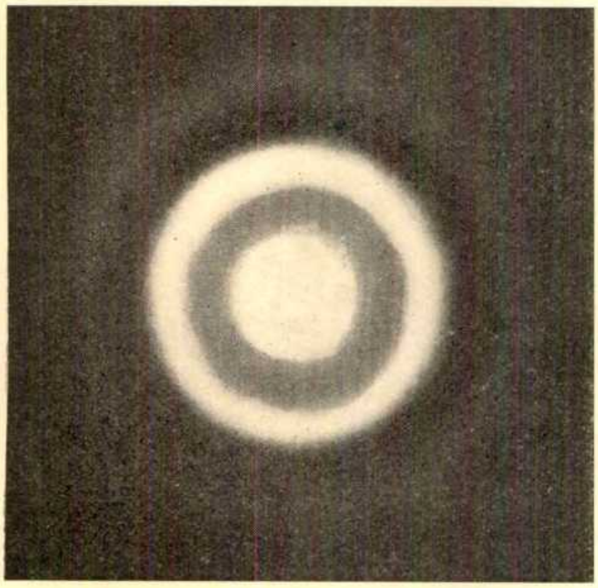

Fig. 3. Electron diffraction pattern of film deposited from uranium nitrate in alcohol plating solution shows that during some stage of preparation, or microscope examination, conversion to the dioxide has occurred

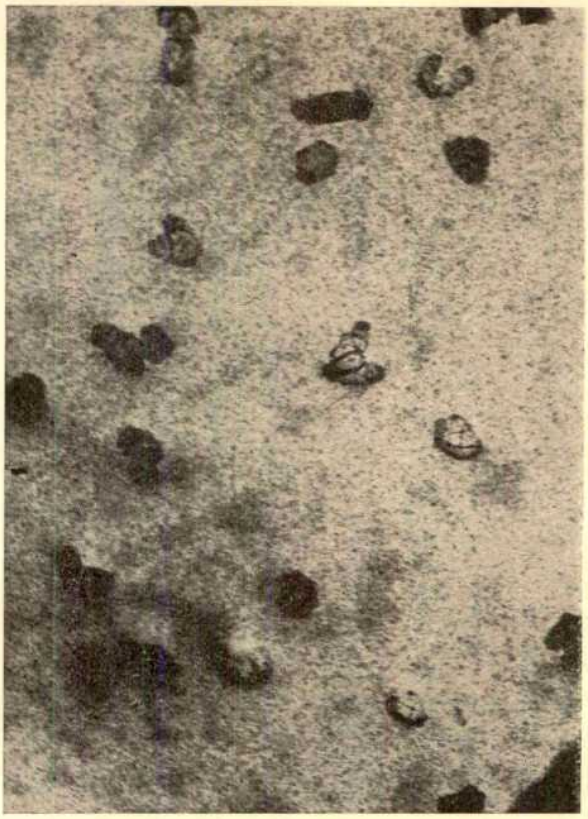

Fig. 4. Electronphotomicrograph showing surface structure of UO_2 film obtained deposited from uranyl nitrate plating solution (× *c*. 12,000)

The described plating method has been applied to a wide range of elemental compounds including uranium and thorium[2,3], the rare earths[4], cæsium, cobalt, iron, zinc, strontium and calcium[5], and plutonium[6]; it is possible that the method may find routine application in electron diffraction where one can never have too many preparation techniques available.

The possibility of using a similar technique for the preparation of thicker, self-supporting films (up to $500\ \mu g/cm^2$), having an area in the region of $1\ cm^2$, is at the present time under development[8]. Such films would find considerable application within nuclear physics.

We thank the director of research, Dr. M. Higatsberger, for facilities and Dr. H. Bildstein, director of the chemical institute, for his advice. One of us (W. P.) thanks Prof. Nils Ryde, Gothenburg, for the leave of absence granted to him and for his advice.

CYTOCHEMICAL AND IMMUNOCHEMICAL ANALYSIS AT THE ELECTRON MICROSCOPY LEVEL: OBTAINING CONTRASTING ANTIBODIES BY USE OF IODINE

By L. B. MEKLER, S. M. KLIMENKO, G. E. DOBREZOV, V. K. NAUMOVA, YU. P. HOFFMAN and PROF. V. M. ZHDANOV

D. I. Ivanovsky Institute of Virology, Academy of Medical Sciences of the U.S.S.R., Moscow

MODERN histochemistry offers various methods of histochemical analysis[1]. These methods have been developed on the basis of optic microscopy. However, limitations due to the low-resolving capacity of optical microscopes do not allow the use of these methods for investigating histochemical problems at the molecular level.

With the use of electron microscopes the only way of revealing two different neighbouring structures or substances is by contrasting. The intensity of blackening of a photographic plate (other conditions being equal) is determined by the quantity of electrons reaching each particular area of the plate. The quantity of electrons loosened by the original electron pencil passing through the object is determined by that part of the electron pencil which is scattered inelastically and elastically by the atoms of the object. The first effect is determined by the correlation between the energy of the falling electrons and the structure of electron levels of an atom. It occurs if the energy of the falling electrons is equal to or more than the energy which corresponds to characteristic frequencies of the element spectrum.

If interaction between the electron pencil and the atoms of the element is inelastic, the representation of the biological object in principle can be obtained as a mosaic which reflects the distribution of the chemical element in the preparation. In this case the change of the electron energy (for example, by a change of the accelerating voltage) and construction of an image of the object examined by inelastically scattered electrons renders it possible to obtain some photographs which reflect the distribution of different elements in the object investigated.

If one proceeds from the *K*-lines of the X-ray spectrum the excitation energy of which is closest to the energy of electrons now used in electron microscopy, a simple calculation shows that micro-elements most interesting from the biological point of view (manganese, iron, cobalt, zinc, molybdenum, silver, iodine, mercury, lead, etc.) may be detected with an electron microscope operating at 7–100 kV with sufficiently precise stabilization of the voltage (the error should not exceed 0·001 per cent), a high resolving power ($\sim$ 2 Å) and corresponding system of construction of image. At present such microscopes do not exist. However, possibilities of the method already mentioned may make the designing of such electronic microscopes very desirable.

The second effect, that is, elastic scattering, is determined in common by the size of the atom. The higher the atomic number of the element, the more intense (other conditions being equal) is the scattering of the electrons by its atoms.

This effect apparently cannot be used for identification of elements, because the additivity of scattering effect on many atoms does not allow estimation of the part brought in common scattering by every element.

At present, electron microscopy does not render it possible to distinguish between elastic and inelastic scattering. Both effects are determined by the size of atomic cross-section for electron scattering. If the atomic number is increased the cross-section for electron scattering is also increased. Owing to this it is easy to distinguish two structures containing atoms with widely distant atomic numbers, but it is difficult to do this when the atomic numbers are neighbouring. For this purpose the heavy elements (osmium, manganese, iron, uranium) are used as specific markers for increasing the contrast of objects. The specificity of a marker is highly increased by combining the iron-contained protein, ferritin, with antibodies. The possibility of obtaining antibodies against 'artificial' antigens[3,4] suggests the idea of developing a method of electron-microscopic immunochemical analysis which is highly sensitive and unique as a specific immunochemical method, on one hand, and render it possible to detect both the macromolecules and usual smaller molecules of organic substances on the other. Hence, it is evident that the method of obtaining contrasting antibodies is of great importance.

However, the method of ferritine antibodies has two significant disadvantages; for example: (1) obtaining a sufficiently pure complex molecule of antibody–ferritine is very difficult and laborious; (2) a sharp increase in the size of the immunologically active molecule may impede its diffusion to the areas of antigen localization in the cell.

To eliminate these disadvantages, attempts were made to develop a method based on combining the antibody molecule with a small organic molecule containing mercury[5,6]. This method requires a scarcely available mercury-containing organic compound and is also very laborious.

It is well known, however, that up to 20 iodine atoms may be included in the antibody molecule without losing its specific activity[7,8]. The problem is whether this amount of iodine is sufficient to make the antibody thus iodized 'black' enough, that is, contrasting in the field of an electronic microscope against a background of the neighbouring areas of the preparation.

At present there are no theoretical data allowing one to calculate precisely the dependence between the quantity of atoms with a particular atomic number and the level of scattering of electrons produced by them, that is, the value of blackening observed and the contrast in the electron microscopy. On the basis of the theoretical approach[2], Valentine[10] developed an equation making it possible to calculate as a guide the number (N) of atoms with the atomic number (Z) which must be distributed uniformly over the surface of an object or in its volume to obtain a minimally detectable increase in the contrast at the particular voltage used for electron-microscopic examination.

By using this equation, Pearse[1] carried out a similar calculation for contrasting with OsO_4. According to his results sufficient contrast may be obtained by introducing one residue of OsO_2 per 400 Å (ref. 2) of the membrane surface. Since the cross-section of the antibody is 8000 Å (ref. 2) and the atomic number of iodine (Z) is 53, it is evident that for obtaining a contrast analogous to that produced by osmium one should introduce about 40 iodine atoms into the antibody molecule.

An important factor for obtaining the contrast is the distribution of iodine atoms in the antibody molecule, determined in its turn by the distribution of tyrosine residues. Unfortunately such data are lacking.

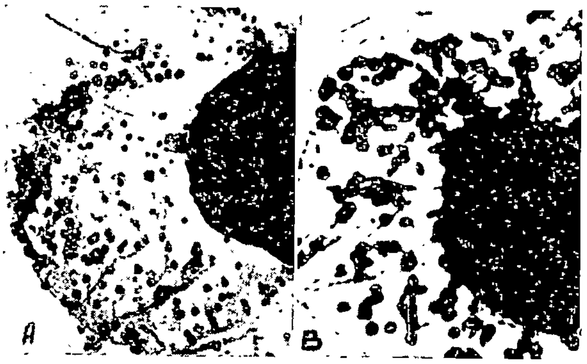

Fig. 1. Influenza virus *PR*-8 adsorbed on the chick red blood cell stroma, *A*, treated with OsO_4; *B*, treated with iodized immune γ-globulin (× *c*. 7,500)

We have attempted, however, to estimate more precisely the possibility of obtaining a sufficient contrast by iodizing. For this purpose we used the photographs taken in the course of electron-microscopic examination of thin tissue sections of the murine thyroid[11]. Thyreoglobulin contains 0·8 per cent of iodine[12]. One could hope to detect it by electron-microscopic examination. Indeed, the photomicrographs showed several types of granules with high-density levels. Although there is no direct evidence that these granules are really the granules of thyreoglobulin, their unusual character, specificity for the thyroid gland and the characteristic dynamics of their occurrence suggested the possibility of obtaining a sufficient contrast by using iodized antibodies. On the basis of the aforementioned considerations the investigations described here were performed. Influenza virus (strain *PR*-8) was used as the antigen, and hyperimmune polyvalent horse serum as the source of antibodies.

(1) An allantoic culture of influenza virus (strain *PR*-8) was purified by means of ultrafiltration[13] and differential centrifugation, as a result of which a virus suspension in 1 per cent ammonium acetate solution was obtained.

(2) γ-Globulin was prepared from hyperimmune horse serum[14]. The solution obtained was diluted with sodium bicarbonate solution, down to the γ-globulin concentration of 2 per cent and 1·5 per cent concentration of sodium bicarbonate. The solution was cooled down to 0° to + 2° C in an ice bath with constant stirring by a magnetic stirrer and gradually was added dropwise 0·2 N iodine solution in ethanol at a rate of about 0·01 ml./min. The amount of iodine added corresponded to 10 per cent of the weight of γ-globulin. The solution gradually became coloured and at the end of the iodine addition turned yellow, with a decrease of *p*H from 8·3–8·4 to 8·2–8·1. Addition of iodine lasted 2–2·5 h. Then the solution was poured into a 'Cellophane' sac and dialysed overnight against 1 per cent ammonium acetate solution, *p*H 7·0. A colourless solution was centrifuged at 8,000–10,000 r.p.m. for 20 min. The residue was discarded and the solution was used as the source of iodized antibodies.

(3) The antigen–antibody reaction was performed in two ways: (i) a sodium periodate solution was added to the virus suspension. The non-reacted sodium periodate was reduced with glucose[15]. Then the virus-containing suspension was mixed with chick red blood cells stroma, adsorbing the virus on the stroma and adding the iodized antibodies according to the method described[15]; (ii) the virus suspension was mixed with antibodies, after which the mixture was spread over a colloid membrane.

(4) The initial non-iodized anti-influenza serum and the iodized horse anti-rabic serum were used as controls.

(5) The preparations were examined with an electron microscope, model *JEM–5Y*, at an accelerating voltage of 80 kV. The expositions and the enlargements of the test and the control preparations were identical. Photographs of the materials were taken simultaneously at all stages.

Seligman[16] pointed out that it is very desirable to introduce iodine into preparations examined with electron microscopes. When iodizing was performed, we tried to introduce an amount of iodine into the antibody molecule maximal from the point of view of preserving the specific activity. The first experiments showed sufficient stability of the iodized antibodies and the amount of iodine introduced was increased up to 5 per cent. This amount is more than twice as high as that calculated. In practice, 10 per cent of iodine is added to the γ-globulin solution, since only ~ 50 per cent of iodine added is incorporated into the γ-globulin molecule. Table 1 shows the results of determining the antibody titres in the hæmagglutination inhibition reaction.

Table 1. CHANGES IN THE TITRES OF γ-GLOBULIN RESULTING FROM IODIZING

No. of experiments	Titres of the hæmagglutination inhibition reaction	
	Initial	After iodizing
1	1 : 5,120	1 : 1,024
2	1 : 512	1 : 512
3	1 : 512	1 : 128

However, since the analysis of the iodine content in the antibodies was not performed, it was difficult to say what was the real content of iodine in the antibodies. Still, the examination of the preparation with electron microscope demonstrated that, in both the first and the second

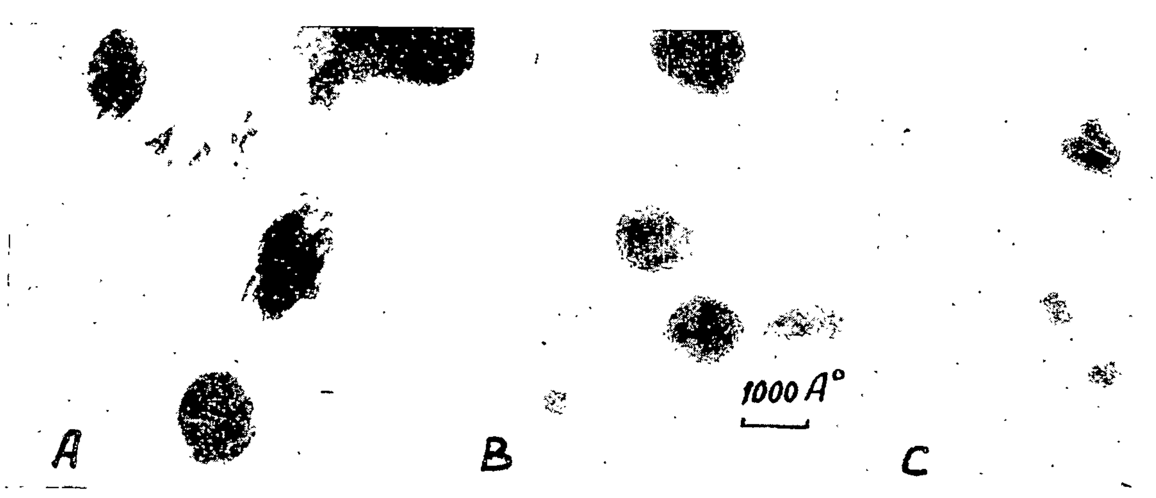

Fig. 2. Influenza virus *PR*-8 mixed with γ-globulin, *A*, with iodized immune γ-globulin; *B*, with non-iodized immune γ-globulin; *C*, with iodized anti-rabic γ-globulin (× 100,000)

variations of the reaction virus–antibodies, the contrast is observed in the presence of sufficient specificity.

Fig. 1*A* shows a preparation of influenza virus *PR*-8 adsorbed on the chick red blood cell stroma contrasted with OsO_4 according to the usual procedure. Fig. 1*B* shows an analogous preparation treated with iodized antibodies but not contrasted with OsO_4. The complex virus-antibody is clearly seen on the red blood cell stroma. Fig. 2*A* shows a preparation obtained on mixing a suspension of influenza virus *PR*-8 with iodized immune γ-globulin. A sufficient contrast of the complex virus–antibody is clearly seen.

Fig. 2*B* shows a preparation obtained in the same way by mixing a suspension of influenza virus *PR*-8 with non-iodized immune γ-globulin. The complex virus–antibody is seen, as expected, in the form of a light grey diffuse zone.

Fig. 2*C* shows a preparation, obtained with iodized anti-rabies horse γ-globulin instead of iodized anti-influenza γ-globulin. The virus particles are seen in the form of greyish diffuse spots.

The photomicrographs are demonstrating an undoubtedly sufficient level of contrast obtained with iodized antibodies. However, it should be remembered that the final conclusion as to whether iodized antibodies are applicable for cytological investigations with the use of electron microscopes may be drawn only on the basis of investigating ultra-thin tissue sections treated with similar antibodies.

SORPTION OF WATER BY WOOL KERATIN

By J. G. DOWNES and P. NORDON

C.S.I.R.O. Division of Textile Physics, Wool Research Laboratories, Ryde, Sydney

In a recent communication[1], Dr. J. L. Morrison distinguishes a water-content range of 35–42 per cent (relative to dry weight) in which he proposes that water is thermodynamically bound to wool keratin. His proposal is based on the results of experiments in which water vapour is slowly withdrawn via a capillary tube from a flask holding a wool sample initially containing free water, air being absent. It is our opinion that water is not bound to keratin in the proposed range (*BC* in Morrison's notation) and that his observations result from a failure to maintain the temperature throughout his sample sufficiently uniform. Our conclusions are based on theoretical grounds and are supported by results we have obtained from an experimental arrangement similar to that described by Morrison but used with a much reduced evacuation rate to obtain more nearly isothermal conditions.

The important role of temperature in the wool–water sorption system is not always fully appreciated. Two examples may serve to emphasize the magnitude of the effect: (1) if the water content of a wool sample near saturation is changed under adiabatic conditions by 1 per cent, then the temperature of the sample will change by about 12° C. (2) In a system initially containing water vapour at saturation pressure at 20° C, if the temperature is increased by 1° C while the vapour pressure is maintained constant, then the relative pressure (relative humidity) is reduced to 94 per cent and the corresponding equilibrium water content of wool is reduced from 33 to about 26 per cent.

Owing to the presence of these strongly coupled effects the mechanisms of heat transfer are of prime importance in experimental studies of sorption. It is not easy to make observations of changes in water content which are characteristic of the wool keratin alone and uninfluenced by heat effects. This difficulty has already been considered by King and Cassie[2]. It is particularly apparent in vacuum systems where heat transfer by convection is not present.

In Morrison's experiment water is removed from the sample at an initial rate of $2 \cdot 2 \times 10^{-4}$ g/sec. Assuming the heat of evaporation as 580 cal/g, then 0·128 cal/sec must be transferred to the sample. Transfer of heat to the interior of the wool mass is effective by conduction only at the vapour pressures used. Assuming the conductivity of the sample is effectively that of the water vapour present, for which we take the value $4 \cdot 5 \times 10^{-5}$ cal/sec/cm/° C (ref. 3) and assuming a spherical sample of diameter 5 cm, it can be shown[4] that the necessary heat transfer can only take place if the centre of the wool mass is about 45° C below the surface temperature. It is clear, therefore, that either the experiment is not isothermal or evaporation is not occurring uniformly through the sample.

If evaporation occurs only from the outer part of the mass a much smaller temperature difference is required to sustain the necessary heat flow. In any actual experiment the interior temperature of the mass will fall only slightly to correspond with the rate of evaporation from the interior, which is limited by the relatively slow rate at which heat can be conducted to it. During evacuation, therefore, the source of water is essentially only the outer region of the wool mass. In the range *AB* (Morrison's notation) the free water content of the outer region becomes progressively reduced and is lower than the average for the whole sample; however, the vapour pressure is constant at the saturation value.

After point *B* is passed it is our opinion that the water content of the outer part of the wool mass is being reduced during evacuation to values progressively lower than the saturation value (that is, that usually taken as 33–35 per cent for unmodified wool keratin[5]), while in the interior of the mass free water remains present but with its boundary receding towards the centre. The vapour pressure during evacuation will fall below the saturation value (this is manifested by the fall over the range *BC* in the amount removed per 20-min evacuation). The vapour pressure of the free water inside the mass falls correspondingly because it is at the lower temperature necessary to maintain heat flow. However, in the range *BC* the average moisture content for the whole sample is above the usually accepted saturation value for keratin[5].

This appears to us the probable explanation for the anomalous region *BC*, rather than the existence of 'capillary water'.

While there is free water present throughout the sample and the temperature is uniform there is thermodynamic equilibrium and consequently no redistribution of water during the 12-h resting periods. Hence, non-uniformity in moisture distribution persists and the average moisture content of the wool mass is therefore not an indication of the condition of the outer region which is the effective source during evacuation.

After all free water has been removed from the outer regions there will be a tendency during the 12-h periods for water to be transferred from the interior of the mass to the surface, since the latter then has an equilibrium vapour pressure below the saturation value. Calculation of the time required for redistribution is difficult; some estimates indicate, however, that complete equilibrium is unlikely to occur in a 12-h period because of the thermal effects discussed earlier. Moreover, in no circumstances can the water content of the surface rise above the saturation value of 33–35 per cent. Hence, non-uniform distribution persists in this case also. We consider that these are the conditions prevailing in the range *BC* and that the progressive fall in the amount removed per evacuation is a measure of the steady depletion of the sample surface.

A further comment concerns the relative vapour pressure at the point *C*. Under the experimental conditions quoted by Morrison we believe the rate of evacuation, at least in the *ABC* region, to be almost completely determined by the resistance offered by the capillary tube and by the vapour pressure prevailing in the flask and not to any significant extent by desorption rate processes within the wool fibres. This would clearly be true while free water was present at the surface of the mass, while at high values of water content (but below saturation) the rate at which water can be released from wool fibres is several hundred times greater than the evacuation rate used by Morrison of 4–5 per cent water content per 20 min, or 4×10^{-3} per cent/sec. Thus Roberts and Haly[6] report initial desorption rates of 1 per cent water content per second, while King[7] and Nordon *et al.*[8] quote values of diffusion coefficient of about 10^{-7} cm^2/sec, corresponding to desorption times of a few seconds. Hence the vapour pressure in the flask is virtually in equilibrium with the wool and this together with the capillary resistance determines the evacuation rate. (The important point should be noted, however, that uniformity of vapour pressure within the flask does not imply uniformity of water content throughout the sample nor uniformity of temperature).

Since the capillary flow over the range of vapour pressures encountered follows Poiseuille's law, the mass transfer per second is proportional to the square of the pressure drop along the capillary. The evacuation rate in the range *AB* is 0·26 g/20 min, corresponding to saturation vapour pressure. The evacuation rate at point *C* is 0·20 g/20 min, so that the relative vapour pressure at point *C* is $(0{\cdot}20/0{\cdot}26)^{1/2}$, that is, 0·876 rather than the 0·99 quoted by Morrison. (It is not clear from his communication how the figures for relative humidity in his table were arrived at.) At a relative vapour pressure of 0·876 the water content of wool has been frequently determined[5] as about 23 per cent, rather than the value of 35 per cent quoted by Morrison. This throws doubt on the interpretation of *C* as a fibre saturation point. It appears to us that *C* could be the point at which the last of the free water is removed from the sample.

We have performed an experiment similar to that of Morrison, using a sample of wool of similar mass and shape. Our capillary tube, however, was selected to offer a much greater resistance to flow, so that the initial evacuation rate was $8{\cdot}7\times10^{-6}$ g/sec, that is, about 1/25 of that used by Morrison. The initial water content of the sample was 160 per cent. Continuous evacuation of the sample was carried on until its average water content was 50 per cent. At this stage the evacuation rate was found to have fallen to $8{\cdot}1\times10^{-6}$ g/sec, despite the slowness of the rate. Evacuation of the sample was then stopped for 60 h. On resuming evacuation it was found that the rate had returned completely to its initial value of $8{\cdot}7\times10^{-6}$ g/sec.

There is no supporting evidence for any such long-term intra-fibre sorption effect in saturated wool as would give rise to behaviour of the magnitude observed. On the other hand, the result of our experiment is consistent with the proposal that, during evacuation, evaporation does not proceed uniformly from the sample, that the outer part of the mass is first depleted of free water, and that during a subsequent long rest period water is slowly transferred from the interior of the mass to bring the surface near to the saturated condition.

The average rate of evacuation was lowered much further still, to $3{\cdot}6\times10^{-7}$ g/sec, and it was then found possible to reduce the water content of the sample to 35 per cent without appreciable fall in evacuation rate from the initial value.

Note. Dr. Morrison has kindly discussed by correspondence some of the aspects raised in our letter. This does not, however, necessarily imply his agreement with our arguments.

OLIGOMYCIN AND ACTIVE TRANSPORT REACTIONS IN CELL MEMBRANES

By Dr. R. WHITTAM, K. P. WHEELER and A. BLAKE

Department of Biochemistry, University of Oxford

THE formation of adenosine triphosphate (ATP) by oxidative phosphorylation in mitochondria is a complex process involving a high-energy phosphate intermediate that has been partly characterized[1]. The antibiotic, oligomycin, appears to inhibit ATP formation by blocking some step in the transfer of high-energy phosphate through this intermediate to ADP[2]. The question arises whether ATP utilization for the active transport of sodium and potassium ions at cell membranes also involves a phosphate intermediate which is affected by oligomycin. Active transport intimately depends on the enzymatic hydrolysis of ATP, and it is now well established that sodium and potassium ions are required together for optimum rates of transport and of adenosine triphosphatase (ATPase) activity. There have been some indications that these ions influence the turnover of a phosphate compound which is formed during this kind of enzymatic activity[21–23,31]. It is the purpose of this article to show that oligomycin is a potent inhibitor of active transport, and that it inhibits the breakdown of a phosphate intermediate which is formed from ATP in cell membranes of kidney cortex. It seems likely that this reaction is responsible for the transformation of chemical energy into osmotic work.

Previous authors have described some effects of oligomycin on membrane transport and its associated ATPase activity. A clear inhibition of potassium uptake was found with liver slices[3]. On the other hand, with red blood cells, Van Rossum[3] found no inhibition, while Glynn[4] found partial inhibition. As regards the membrane ATPase, which is activated by sodium and potassium inhibition by oligomycin, has been shown in red blood cells[5], brain microsomes[5–7] and the electric organ of the electric eel[4,6]. Correlation of the effects on transport and ATPase, activity have not been made, however, and the question has been raised whether the antibiotic inhibits active transport directly, or indirectly by inhibiting the supply of ATP[3–5]. In investigating reactions that might be associated with membrane transport, it is important to conduct experiments with intact cells as well as with fragmented membranes. Intact membranes are, of course, required for active transport to be demonstrable, and red cells and kidney cortex slices have been used in this investigation to monitor ion movements; at the same time, metabolic activity was also measured. A membrane preparation was used to follow the fate of the terminal phosphate of ATP under conditions similar to those occurring in cells.

Red Blood Cells

ATP in these cells is derived entirely from the anaerobic conversion of glucose to lactate, and oxidative phosphorylation is not involved. Since oligomycin is generally believed to inhibit oxidative phosphorylation[2], it was decided to investigate its effect in human red blood cells, to see how it affects other processes.

Sodium and potassium transport. The potassium influx (in µmoles/ml. cells/h) was measured[8] with potassium-42, and was lowered from 2·15 in control cells to 0·75 with oligomycin at a concentration of 20 µg/ml. medium. This represented maximum inhibition of the active influx because 100 µM ouabain caused a fall to the similar value of 0·65. The oligomycin concentration that would give half maximal inhibition would be 1–2 µg/ml. Sodium transport was determined from net movements, and oligomycin and ouabain each prevented the extrusion that was found in the control cells. Controls lost (in µmoles sodium/ml. cells/3·5 h incubation) 3·4, whereas gains of 2·0 and 2·6 occurred in the presence of ouabain and oligomycin, respectively. These results agree with those of Glynn[4], but not those of van Rossum[3]. It is evident that oligomycin is analogous to ouabain so far as sodium and potassium transport is concerned.

ATP hydrolysis. The membrane ATPase activity was measured[9] by determining the orthophosphate (P_i) released from ATP by a preparation of fragmented membranes[20]. The activity (in µmoles P_i/ml. original cells/h) had a value of 1·6 in the presence of sodium and potassium ions, which are required together for optimum activity[10,11]. The hydrolysis was lowered some 60 per cent either by the omission of potassium or by the addition of ouabain or oligomycin (Table 1). The inhibitory effects of oligomycin and ouabain are not additive, because the two together cause only the same degree of inhibition as either alone (Fig. 1).

Comparison of potassium influx in intact cells with ATPase activity in fragmented membranes revealed a parallel inhibition over a range of oligomycin concentrations (Fig. 2). A decrease in ATPase activity went hand in hand with a fall in potassium influx, showing that an effect on one process is accompanied by a similar effect on the other process. The linear relationship in Fig. 2 is derived from comparing the behaviour of intact cells with fragmented membranes, and there are too many objections and assumptions involved to warrant a quantitative comparison of potassium influx/ATP hydrolysed. These results suggest, nevertheless, that oligomycin, like ouabain, inhibits active transport through an action on a membrane ATPase in human red cells.

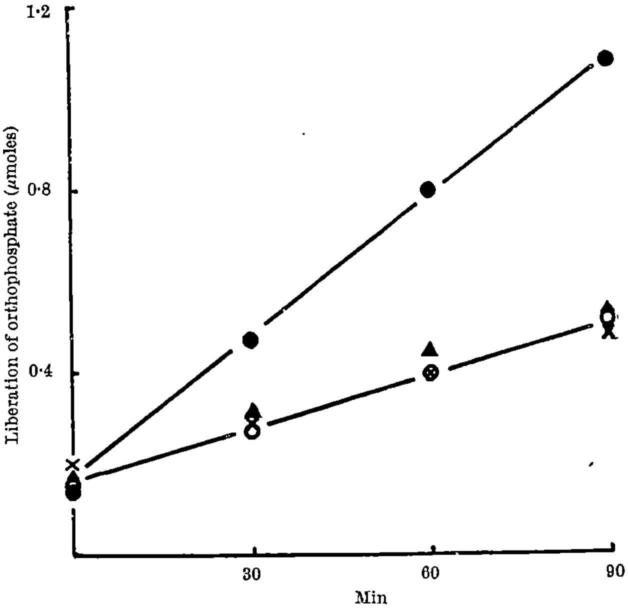

Fig. 1. Effect of oligomycin on the ATPase activity of fragmented erythrocyte membranes. Fragmented erythrocyte membranes (3 mg dry weight) were incubated in a medium of composition: 3 mM ATP; 100 mM NaCl; 25 mM KCl; 1 mM $MgCl_2$; 10 mM *tris*-HCl, *p*H 7·5. Oligomycin was added as a solution in ethanol (1 mg/ml.) and an equal volume of ethanol was added to the other experimental tubes. Controls with no inhibitor are shown (●), with 20 µg/ml. oligomycin (▲), with 0·1 mM ouabain (○), and with both 20 µg/ml. oligomycin and 0·1 mM ouabain by (×)

Lactate production. Oligomycin appears to act on the membrane ATPase and should therefore cause a consequential fall in lactate production at least as great as that due to omission of potassium from the medium[12]. Table 1 shows that lactate produced from glucose (in µmoles/ml. cells/h) was lowered from 3·05 in control cells to 2·55 and 2·60 in the presence of oligomycin or on the omission of potassium, respectively. The fall due to oligomycin was not significantly greater than that caused by omission of potassium. Since potassium ions activate the ATPase and lactate production from outside the cells[12–15] it would appear that oligomycin inhibits the same ATPase. These results do not show whether oligomycin acts on the internal or external surface of the cell membrane—only that it inhibits the mechanism that external potassium

Table 1. INHIBITORY EFFECTS OF OLIGOMYCIN ON CATION MOVEMENTS AND LACTATE PRODUCTION IN INTACT ERYTHROCYTES, AND THE ATPASE ACTIVITY OF FRAGMENTED ERYTHROCYTE MEMBRANES

	Net sodium ion movement	Potassium ion influx	ATPase activity	Lactate production
	← µmoles/ml. packed cells/h →			
Control	−1·0 (3)	2·15 (3)	1·6 (5)	3·05 (10)
0·1 mM ouabain	+0·6 (3)	0·65 (2)	0·5 (5)	—
20 µg/ml. oligomycin	+0·7 (3)	0·75 (2)	0·5 (5)	2·55 (10)
Potassium free medium	—	0	0·45 (3)	2·60 (4)
Incubation medium	10 mM KCl 115 mM NaCl 10 mM *tris*-HCl *p*H 7·5 10 mM glucose	10 mM KCl 120 mM NaCl 10 mM *tris*-HCl *p*H 7·5 10 mM glucose	25 mM KCl 100 mM NaCl 10 mM *tris*-HCl *p*H 7·5 4 mM ATP 1 mM $MgCl_2$	10 mM KCl 120 mM NaCl 10 mM *tris*-HCl *p*H 7·5 10 mM glucose

Figures in brackets show the number of determinations. For ATPase activity and lactate production the values are the means from two experiments. Incubations were performed at 37°.

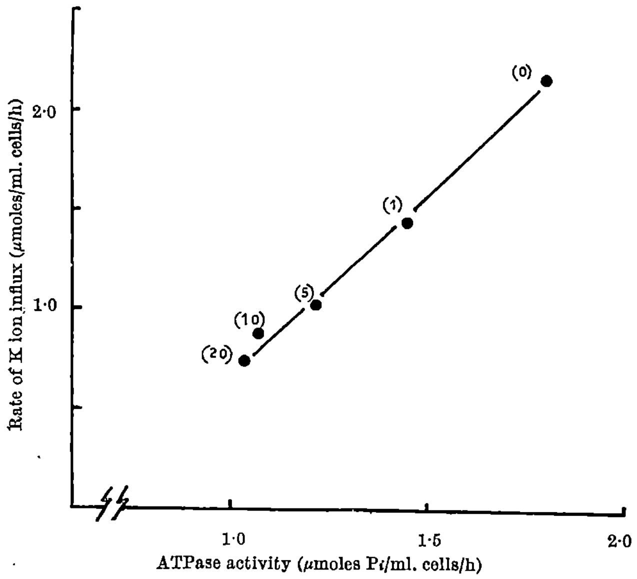

Fig. 2. Comparison of the ATPase activity of fragmented erythrocyte membranes with the rate of potassium ion influx into intact cells in the presence of oligomycin. Concentrations of the antibiotic (μg/ml.) are shown in brackets. The co-ordinates of each point are the means of at least two experimental values

activates, namely, the membrane ATPase. However, the evidence with the kidney membrane preparation (see later) shows that oligomycin is like ouabain in inhibiting the second step of the ATPase reaction, and as this is the one requiring potassium it looks as if oligomycin probably acts at the external cell surface. These results confirm that cessation of active transport, which may be due either to direct attack on the membrane (by ouabain or oligomycin) or to deprivation of external potassium, has a pace-maker effect on energy production manifested by a fall in lactate production.

From knowledge of the glycolytic pathway, it may be taken that each molecule of lactate produced is accompanied by the genesis of a molecule of ATP from ADP. The extent of the stimulation of the lactate production by external potassium is therefore the same as the stimulation of ATP production. If this amount of ATP is that which is utilized for active transport, the ratio of potassium transported/ATP hydrolysed can be calculated: the value is $(2\cdot15 - 0\cdot75)/(3\cdot05 - 2\cdot55) = 2\cdot8$. For net sodium actively transported/ATP hydrolysed the value is $\left(\frac{3\cdot4+2\cdot6}{3\cdot5}\right)\Big/(3\cdot05 - 2\cdot55) = 3\cdot4$ (Table 1). This means that the oligomycin-sensitive components of transport on one hand, and of lactate production on the other hand, yield a value of $2\cdot8 + 3\cdot4 = 6\cdot2$ for the ratio of sodium + potassium transported/ATP hydrolysed. The value is only approximate and is based on several assumptions. Nevertheless, it is remarkably close to that calculated by Sen and Post[16] by a different method. This work with red blood cells shows that all the effects of oligomycin can be explained by an inhibition of processes in the cell membrane without the need to postulate direct effects on metabolism.

Kidney Cortex Slices and Membranes

It was decided to find out if oligomycin affected kidney cells in a way that could also be ascribed to inhibition of transport reactions in cell membranes, rather than by a direct effect on energy metabolism in mitochondria.

Rabbit kidney cortex slices were incubated in a physiological saline medium containing glucose, and their potassium content and rate of oxygen consumption measured[17]. In a typical experiment, oligomycin in a concentration of 10 μg/ml. medium caused a fall in Q_{O_2} (μl. O_2/mg dry wt./h) from 12·6 to 8·7. This is similar to the fall due to cessation of active transport produced either by ouabain or by omission of sodium ions[17]. Comparable falls were found when malate or α-oxoglutarate were metabolites instead of glucose. (Neither oligomycin nor ouabain abolished the response of slices to 2 : 4-dinitrophenol, which caused a stimulation of oxygen consumption.) The maintenance of a high tissue potassium content was also prevented. Thus, in control slices a value (in μmoles/g wet-wt.) of about 50–60 was found, whereas with oligomycin or ouabain it was only about 20. To check that the inhibition was of potassium uptake and not just an increased rate of leakage, slices were first suspended in ice-cold medium in order to deplete them of potassium. The change in potassium content was then found after incubation for 1 h at 37° C. The net uptake of potassium in the controls was 25–50 and was abolished by oligomycin as it was by ouabain. Inhibition of potassium uptake in liver slices has been previously reported[3].

These effects made it worth while to investigate the effect of oligomycin on the membrane ATPase activity. Membranes of renal cortex are sedimented with two of the fractions of a homogenate the nuclear and the microsomal fractions[18–20]. The ATPase of the nuclear fraction was activated about 100 per cent by adding sodium and potassium ions together, and this component of the enzymatic activity was 80 per cent inhibited by oligomycin[20] (20 μg/ml.). The antibiotic did not inhibit the (sodium + potassium)-insensitive ATPase. In the same way, the microsomal fraction was sensitive to oligomycin, the (sodium + potassium) ATPase activity being lowered to the same extent as with ouabain (Fig. 3). The inhibition by oligomycin of the ATPase activity in both the nuclear and the microsomal fractions suggests that it inhibits the same ATPase as ouabain.

Phosphate intermediate in ATP hydrolysis. A valuable way of deciphering transport reactions is to trace the pathway of the terminal phosphate of ATP before it appears as P_i, and several investigators have described the formation of labelled protein when ^{32}P-γ-labelled ATP is incubated with fragmented membranes[21–23]. We prepared γ-labelled ATP (ref. 24) and incubated it with the kidney microsomal fraction, in a similar way to that of Charnock and Post[22]. After 10 sec the ATPase reaction was stopped with trichloroacetic acid (TCA) and the mixture spun down. The radioactivity due to phosphorus-32 in the supernatant fluid was measured in an extract of isobutanol[30]; this gave the $^{32}P_i$ liberated and hence the overall hydrolysis. The sedimented protein was washed several times with a solution of non-radioactive ATP and P_i, and the precipitate then assayed for radioactivity.

Fig. 3 shows that some tracer phosphate was not washed away with cold P_i and became attached to the TCA precipitate. It is perhaps premature to refer to the compound as phosphoprotein, although total phospholipid extraction[22] shows that it is unlikely to be phospholipid. We prefer, as Pressman[25] does in a similar situation, to refer to the intermediate as protein-bound phosphate.

The striking feature of the labelling is that it is dependent on the sodium and potassium concentrations. In the presence of sodium alone, the labelling was some 5–15 times greater than when potassium was present. Put another way, potassium prevents the labelling promoted by sodium. This feature is the converse of the hydrolysis that was taking place, because potassium stimulated hydrolysis some 200 per cent at the same time that it abolished labelling. Very little labelling was found when potassium ions were present without sodium. Ouabain had a slight effect on the formation of the protein-bound phosphate with sodium alone. However, with sodium plus potassium, ouabain caused the labelling to increase about 10-fold. These results are similar to those of Charnock and Post[22] in demonstrating the formation of a phosphate intermediate in the fission of ATP by a kidney-membrane preparation. The extent of the forma-

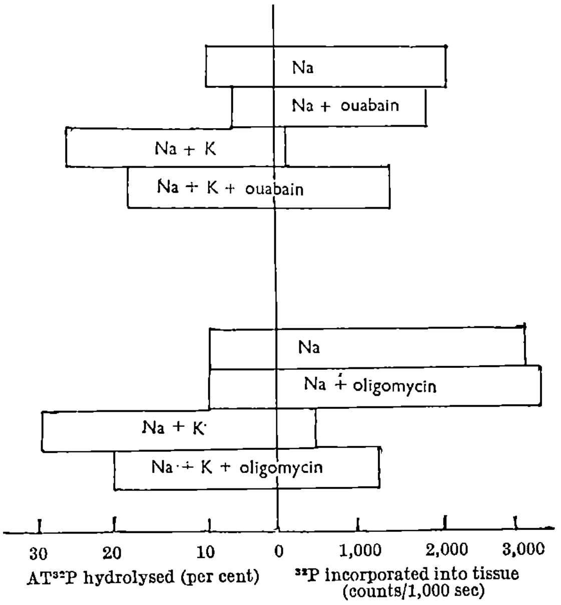

Fig. 3. Similarity between oligomycin and ouabain in opposing the action of K^+ during the ATPase reaction. Samples of the microsomal suspension (prepared according to the method of Charnock and Post[22]) were incubated for 10 sec at 37° in a medium containing 50 μM-ATP (labelled in the γ-position with ^{32}P: sp. activity 1·2 μc./μmole); 64 μM $MgSO_4$; 120 mM NaCl; and 40 mM imidazole, adjusted to *p*H 7·6 with 0·5 N HCl. The medium was modified by the addition of KCl (16 mM), ouabain (0·2 mM), or oligomycin (ethanolic solution: 10 μg/ml.) as indicated; ethanol (1%) was added to the appropriate controls. The reaction was stopped by adding cold TCA solution (final concentration, w/v, 5%) to the incubation mixture, and the precipitated protein spun down after cooling in ice. In order to follow the hydrolysis of the ATP, the TCA supernatant solution was decanted into a solution of acidified ammonium molybdate and the phosphomolybdate complex formed was then extracted in isobutanol/benzene (ref. 30). The radioactivity of samples of the latter extract was measured. The precipitated protein was washed 3 times by resuspension in a cold solution of TCA (5% w/v), *tris*-phosphate (2 mM) and ATP (2 mM). The washed precipitate was then dispersed in a solution of scintillant containing 5% (w/v) 'Hyamine 10*X*' and the radioactivity measured. All measurements of radioactivity were carried out using a liquid scintillation technique. Background counts were about one a second and the ATP added to each tube was equivalent to about 29×10^4 counts/100 sec. In the experiment presented here, the zero time values for the washed precipitates were about 1,500 counts/1,000 sec: these values have been subtracted from those for the incubated samples. Other experiments, using (^{14}C)-labelled ATP and inorganic phosphate, have shown that the labelling of the tissue which is sensitive to Na^+ and K^+ is not due to the incorporation of ATP, or $^{32}P_i$ released into the medium

tion of the protein-bound phosphate is the inverse of the overall degree of hydrolysis, as shown by the effects of potassium and ouabain.

In view of the similarity of the effects of oligomycin and ouabain described here, the influence of the antibiotic on the formation of protein-bound phosphate was examined. In each respect its action was like that of ouabain (Fig. 3). It did not interfere with activation by sodium, and it promoted labelling by counteracting the effect of potassium. Again, the extent of labelling was opposite to the degree of ATP hydrolysis, the greater the hydrolysis the lower the labelling and *vice versa*. Attempts to demonstrate similar effects with red cell membranes have so far been unsuccessful. These results show, however, that in kidney cortex, as in red cells, oligomycin and ouabain have very similar effects on a number of membrane reactions.

Regulation of Respiration and Glycolysis

These results add to earlier ones in suggesting that the rates of lactate production and oxygen consumption may be regulated by the activity of membrane ATPases concerned in active transport. Lactate production has previously been thought to be unaffected by the rate of active transport in human red blood cells[26]. However, it now appears that a small fraction, equal to about 0·5 μmole lactate/ml. cells/h, is sensitive to cessation of active transport[12]. The same fall in lactate occurs whether transport is stopped with ouabain, oligomycin or by omission of external potassium. The mechanism by which these agents regulate lactate production would appear to be through their effect on the membrane ATPase. Thus, sodium and potassium transport requires ATP, and when it is stopped there will be changes in the balance of ATP, ADP and P_i, and perhaps in the ratio of NAD and NADH. The fluorometric and spectrophotometric observations of Aubert, Chance and Keynes[27] in the electric organ of *Electrophorus electricus* show a metabolic response to electrical activity which suggests that glycogenolysis may be stimulated as a result of increased active cation transport. This would be similar to the effects with red blood cells.

The results with kidney slices also show that the effects of oligomycin on oxygen consumption can be attributed to inhibition of the ATPase of active transport. A part of the oxygen consumption of the slices appears to be regulated by the activity of the membrane ATPase[17,28], and it is particularly striking that oligomycin inhibits the enzymatic activity to the same extent as ouabain.

Mode of Action of Oligomycin

The effects of oligomycin described here leave no doubt that it inhibits transformations of energy from ATP into osmotic work in cell membranes. Oligomycin acts like ouabain on cell membranes, but the two compounds are not the same in their action on mitochondria because ouabain appears to have no effect on mitochondrial metabolism[28]. There appear to be at least two steps in the reaction coupling ATP hydrolysis with osmotic work - one requiring sodium and the other potassium. By analogy with work with red cell ghosts[13,14] and intact cells[15,29,31], sodium would act from inside and, as a cofactor, facilitate the formation of the protein-bound phosphate. It seems likely that the intermediate might have a high-energy character because no osmotic work is associated with this step, the intermediate still being formed in the presence of ouabain or oligomycin. Potassium would act from outside and promote the breakdown of the intermediate. It is this latter reaction which may be the key to the active transport mechanism, since the energy transformation is associated with this reaction; P_i is liberated to the inside of the cell, and sodium migrates outwards and potassium inwards. The reactions may be represented thus:

$$\text{ATP} + \text{protein} \xrightarrow[\text{internal Na}]{\text{activated by}} \text{protein-bound phosphate} + \text{ADP}$$

$$\text{Protein-bound phosphate} \xrightarrow[\substack{\text{inhibited by}\\ \text{ouabain and}\\ \text{oligomycin}}]{\substack{\text{activated by}\\ \text{external K}}} \text{protein} + P$$

$$\text{ATP} + \text{internal Na} + \text{external K} \dashrightarrow \text{ADP} + \text{internal K} + \text{external Na} + \text{internal } P_i$$

The effects of oligomycin on membranes of red cells and kidney cortex raise the possibility that there may be similarities in the kind of intermediate implicated in energy transformation in mitochondria for ATP formation, and in cell membranes for ATP utilization. The results recorded here do not support the view that oligomycin affects active transport indirectly by an inhibition of energy supply in mitochondria. It should be borne in mind that most of the previous work on oligomycin has been performed with mitochondria, from which its mechanism of action has been deduced. The present work directs attention to three points in this connexion. First, our results show that oligomycin has other inhibitory effects in cells and is not a specific inhibitor of a mitochondrial transphosphorylation reaction. Secondly, although the toxic action of the antibiotic is said to be due to its inhibition of oxidative phosphorylation, the present results pose the question whether some of its toxic action might also arise from poisoning of active transport in the body cells generally. This would cause a leakage of potassium from cells into the circulation and might so raise the plasma potassium concentration as to stop the heart contracting. Thirdly, in work on the mechanism of action of oligomycin in mitochondria, complications will arise unless the preparations used are free from fragments of cell membranes. These are the wider implications of the present work. The general conclusion is that oligomycin acts at two sites in cells—the cell membrane and mitochondria—and that its effect at both sites is to inhibit the transformation of energy. We have shown that key reactions in active transport are the formation and breakdown of a phosphorylated intermediate derived from ATP. Sodium ions are required for its formation, whereas potassium ions catalyse its hydrolysis; ouabain and oligomycin are alike in inhibiting this hydrolysis. Work on the chemical characterization of this intermediate is in progress.

We thank Pfizer, Ltd., for a gift of oligomycin. The work was supported by grants from the U.S. Public Health Service and the Rockefeller Foundation. One of us (K. P. W.) was in receipt of a grant from the Department of Scientific and Industrial Research.

ELECTRON HISTOCHEMICAL EXAMINATION OF OXIDATIVE ENZYMES AND MITOCHONDRIA

By Dr. K. OGAWA and Prof. R. J. BARRNETT

Department of Anatomy, Yale University, School of Medicine, New Haven, Conn.

HISTOCHEMICALLY, mitochondria have been shown to possess oxidative enzymes such as succinic dehydrogenase (SDH) and dihydronicotinamide-adenine dinucleotide diaphorase (NADH–D)[1–6]. The work recorded here deals with the electron microscopic demonstration of heterogeneity among mitochondria in terms of the oxidative enzymatic activity and the fine structural localization of enzymatic activity in mitochondrial cristæ, using tetrazolium salts as electron acceptors.

Small pieces (< 1 mm^3) of rat heart muscle were fixed in 6·25 per cent hydroxyadipaldehyde[7], in 0·1 M cacodylate buffer, *p*H 7·6, containing 8 per cent sucrose for 30–60 min at 0°–4° C. After fixation, these were washed in cold cacodylate buffer thoroughly, rinsed in 0·1 M phosphate buffer, *p*H 7·6, and incubated in substrate media (0·3 ml. of 250 mg per cent tetra nitro-blue tetrazolium chloride (TNBT), 1·5 ml. of 0·1 M sodium succinate, 1·2 ml. 0·1 M phosphate buffer, *p*H 7·6, and 0·25 g of sucrose for SDH; 0·3 ml. 250 mg per cent TNBT, 0·3 ml. 0·1 NADH, 1·0 ml. 0·1 M phosphate buffer, *p*H 7·6, 1·4 ml. of distilled water and 0·25 g of sucrose for NADH–D) for 10–30 min at 0° C or room temperature. After incubation, the blocks were fixed in cold 1 per cent buffered osmium tetroxide for 1 h, dehydrated through graded alcohols and propylene oxide, and embedded in a mixture of 'Epon–DDSA–DMP-30'. Ultra-thin sections were cut by an 'LKB' ultratome, mounted directly on grids and examined with an R.C.A. 'EMU-3F' electron microscope without post-staining.

Homogenates of rat heart muscles were also made and the mitochondrial fractions were obtained by the method of Luck[8]. Portions of the fractions thus obtained were negatively stained to demonstrate elementary particles[9–12]. Other portions were also incubated in substrate media for SDH, fixed in hydroxyadipaldehyde, post-fixed in osmium tetroxide, ruptured in 1 mM phosphate buffer, *p*H 7·2, or de-ionized distilled water, and spread directly over 'Formvar'-coated grids for the electron microscopic observation. Pellets were also made following incubation, fixed in both hydroxyadipaldehyde and osmium tetroxide and treated in the same manner as blocks of heart muscle. Substrate-free media as well as media containing inhibitors (sodium malonate and iodoacetic acid) were used for controls.

Amorphous electron opaque formazans of TNBT, which were absent in the control specimens, were localized at or near the sites of enzymatic activity. Mitochondria could be classified into three varieties depending on the distribution of reaction: completely reactive ones containing deposits of formazan over all the cristæ (Fig. 1), partially reactive ones containing formazan deposits over some or few of the cristæ (Fig. 2), and unreactive ones containing no deposits of final product (Fig. 1). It was not uncommon to find a mitochondrion positive for this reaction lying adjacent to a mitochondrion which was completely unreactive histochemically (Fig. 1). These findings not only occurred for mitochondria situated between myofibrils but also for those in the peripheral sarcoplasm. This heterogeneity of enzymatic activity among individual mitochondria of the same regions of heart muscle was also observed in the moderately intact mitochondrial fragments obtained in the fractionated specimens.

Although these findings may be due to uneven penetration of the ingredients of the substrate media into the blocks, this phenomenon was repeatedly observed in areas close to the peripheral surface of the blocks where penetration of the ingredients of the substrate media are moderately even. The same findings in pellets of

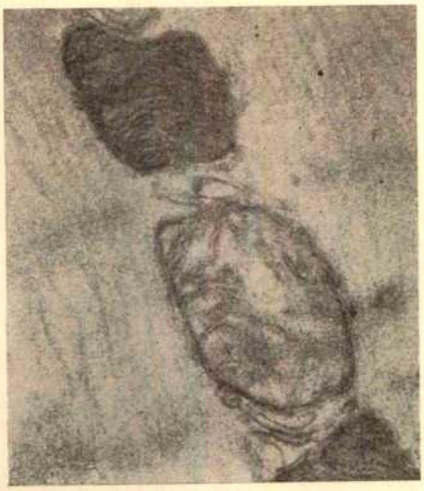

Fig. 1. Rat heart muscle mitochondria, SDH activity, showing a completely unreactive mitochondrion between two mitochondria showing reaction on all the internal membranes. (× *c.* 47,000)

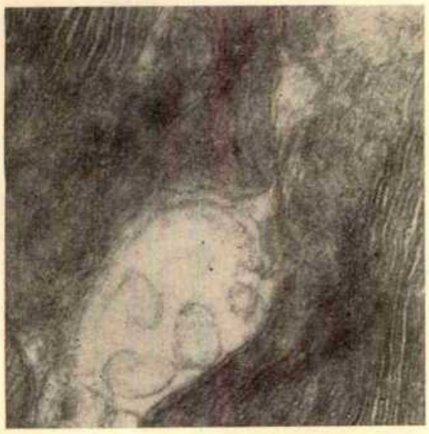

Fig. 2. Rat heart muscle mitochondria, NADH–D activity, showing spotty reaction confined to only some of the cristæ. (× *c.* 44,000)

mitochondrial fractions further substantiate the finding in blocks. Furthermore, since those mitochondria in pellets which were positive for enzymatic activity revealed formazans over the entire area of mitochondria, uneven penetration of substrate media is unlikely. The partial reaction confined to some of the cristæ in some of the mitochondria in blocks was probably due to partial inhibition during the process of fixation in hydroxyadipaldehyde. The heterogeneity among mitochondria may be explained by difference in functional stages or in the age of the mitochondria.

In mitochondria positive for oxidative enzymatic activity, the formazan deposits were confined to inner mitochondrial membranes and cristæ. Under high magnifications, formazans appeared localized as or on particles contained within osmiophilic layers of the cristæ. The size of particles contained in cristæ was in the range 60–90 Å. This particulate appearance of formazans in the cristæ was more clearly seen in the enzymatically active mitochondria contained in the pellets (Fig. 3). Formazans were also observed as or on spherical particles, 50–85 Å in diameter, in the cristæ of ruptured mitochondria, giving a linear, beaded appearance.

Mitochondria from fractionated material, negatively stained with phosphotungstic acid (PTA), revealed elementary particles, 60–90 Å in diameter, in or associated with mitochondrial membranes (Fig. 4). This finding was in good agreement with findings of Smith[9] and others[10–12], but the negatively stained particles were histochemically unreactive. However, when ruptured mitochondria were first incubated in the substrate media fixed in hydroxyadipaldehyde, and then negatively stained with PTA, particles in poor alignment are observed, some of which were dense and others were negatively stained (Fig. 5). Dumb-bell-like structures or particles attached to mitochondrial membranes by stalks were never observed in any of the specimens except those that were negatively stained. The dumb-bell-like structures or particles attached to membranes by stalks[9,12] may be artefacts obtained during the process of negative staining. They may be formed by separation of lipoprotein layers of cristæ by the high degree of dehydration[13,14].

Elementary particles isolated biochemically by Green[15], which were presumed to contain oxidative enzymes, were in the order of 150 Å in diameter and are approximately twice as large as the particulate material observed in the present investigations. This difference in size may be due to differences in types of cells[15] or in the methods used *per se*, or indeed the large particles may be agminates of smaller units. These results corroborate the suggestion that the mitochondrial membranes are composed of

GROWTH-RETARDING EFFECT OF ORAL L-PENICILLAMINE ON SARCOMA-180

By Dr. M. L. LITTMAN, Dr. T. TAGUCHI and Y. SHIMIZU

Department of Health, New York City and Research Institute for Microbial Diseases,
Osaka University, Osaka, Japan

THE action of pyridoxamine dihydrochloride in accelerating the growth of ascitic and solid sarcoma-180 in CF_1 mice has shown the B_6-avidity of this tumour system and pointed to the existence of an exploitable biochemical difference of the tumour from normal host tissue[1]. This difference could be demonstrated *in vivo* by causing retardation of tumour growth with pyridoxine-deficient diet and by reversing this effect with pyridoxamine[1]. Furthermore, the tumour-retarding action of pyridoxine-deficient diet was found to be duplicated with a chemical antagonist of vitamin B_6, L-penicillamine (β-mercaptovaline). It is of interest that another isomer, D-penicillamine, has been in clinical use as a chelating agent for treatment of hepatolenticular degeneration. Subcutaneous injection of L-penicillamine significantly retards the growth of solid form sarcoma-180 in mice maintained on a complete diet, and especially so on pyridoxine-deficient diet[1]. The L-, D- and DL-forms of penicillamine were all found to be active as sarcoma-180 growth-retarding agents, the L-form being the most active. Growth retardation of solid form sarcoma-180 was produced by L-penicillamine whether treatment was started 24 h after tumour implantation or was delayed for 96 h (ref. 1).

This report concerns an investigation of the effectiveness of orally administered L-penicillamine in retarding the growth of solid and ascitic forms of sarcoma-180 in CF_1 mice.

L-Penicillamine was administered for long periods of time via the oral route by admixture with the diet and by addition to the drinking water, and for a short period of time (one week) by daily stomach intubation. Techniques of transplantation and methods of evaluation of tumour growth were as previously described for solid and ascitic sarcoma-180 (ref. 1). Two types of diet were used, that is, a complete diet consisting of standard mouse pellet (Rockland Farms, Inc.) and a pyridoxine-deficient diet (Nutritional Biochemical Corp.) of the following composition, both fed *ad libitum*: vitamin-free test casein 18 per cent, sucrose 68 per cent, vegetable oil 10 per cent, U.S.P. XIII salt mixture No. 2, 4 per cent; vitamins/100-lb. diet: vitamin A (200,000 units/g) 4·5 g., vitamin D concentrate (400,000 units/g) 0·25 g, α-tocopherol 5·0 g, ascorbic acid 45·0 g, inositol 5·0 g, choline chloride 75·0 g, menadione 2·25 g, *p*-amino benzoic acid 5·0 g, niacin 4·5 g, riboflavin 1·0 g, thiamine hydrochloride 1·0 g, calcium pantothenate 3·0 g, biotin 20·0 mg, folic acid 90·0 mg, vitamin B_{12} 1·35 mg.

Retarding effect of oral L-penicillamine on solid sarcoma-180. Ninety 20-g white Swiss CF_1 male mice previously maintained on complete diet each received subcutaneous implantation of 1×10^6 ascitic sarcoma-180 cells. The mice were divided into six groups, and were fed with either complete or pyridoxine-deficient diets (Table 1). L-, D- and DL-penicillamine were incorporated separately, mixed well with pyridoxine deficient diet, and then given *ad libitum*.

The daily oral administration via the drinking-water of 2–2·5 mg L-penicillamine/mouse/day to sarcoma-180-implanted mice for a period of 14 days caused 69 per cent tumour inhibition without mortality (Table 1). Tumour size and weights of the untreated control group of mice on the same diet, on the other hand, were approximately triple that of the L-penicillamine-treated group. The feeding of pyridoxine-deficient diet alone to sarcoma-180-implanted mice caused 48 per cent tumour inhibition, while addition of L-, D- and DL-forms of penicillamine to the deficient diet further increased the degree of tumour inhibition to 71, 70 and 68 per cent, respectively, for the respective isomeric forms. The greatest degree of tumour retardation was produced by the feeding of pyridoxine-deficient diet containing 0·5 mg L-penicillamine/g of diet. Subcutaneous injection of the above isomers of penicillamine to solid sarcoma-180-bearing mice had been reported to cause 55, 41 and 22 per cent tumour inhibition for the respective isomeric forms[1].

During storage of L-penicillamine-enriched pyridoxine-deficient diet, a dark greyish discoloration of the diet resulted which was feared to be a chemical reaction of penicillamine with some component of the diet. In subsequent experiments, therefore, L-penicillamine was administered in the drinking-water or by stomach intubation instead.

Effect of L-penicillamine on survival of solid sarcoma-180-implanted mice. Four experiments were conducted. In experiment 1, fifty mice previously maintained on complete diet were implanted subcutaneously with standard doses of 1×10^6 ascitic sarcoma-180 cells and were divided into two groups, after which they were maintained on complete diet (Table 2 and Fig. 1). One group of 20 mice received L-penicillamine in the drinking-water (0·5 mg/ml.), each mouse consuming approximately 2–2·5 mg L-penicillamine per day (approximately 100 mg/kg/day). Thirty untreated mice remained as controls. All the untreated mice developed solid sarcoma-180 tumours within three days after implantation, which increased regularly and rapidly in size. All mice in this group were dead within 33 days and in every case each mouse bore tumours until death, some as large as its host. The median survival time for this untreated group

* Each mouse received subcutaneous implant of 1×10^6 ascitic sarcoma-180 cells at start of experiment, then maintained on complete diet (Rockland Farms mouse pellet diet).

† Drinking-water contained 0·5 mg L-penicillamine/ml. Each mouse consumed approx. 2 mg penicillamine/day (100 mg/kg). Initial average weight 20 g

was 21 days (Fig. 1). In the L-penicillamine-treated group, on the other hand, there was 74 per cent survival at 30 days and 60 per cent survival at 60 days. Furthermore, the solid tumours of this group were very much smaller than those of the untreated group. In more than half the treated animals, moreover, their tumours became necrotic, decreased progressively in size and were gradually extruded, until they were no longer palpable by the forty-third day of treatment (Fig. 1). Apart from slightly roughened coats at the sixtieth day, L-penicillamine-treated mice were healthy and active. At the end of this treatment period, eleven complete and three incomplete tumour regressions had occurred in 20 tumour-bearing animals. These animals were then maintained on complete diet without L-penicillamine treatment. At the time of this report, 342 days after cessation of L-penicillamine treatment, none of the tumours had recurred *in situ*.

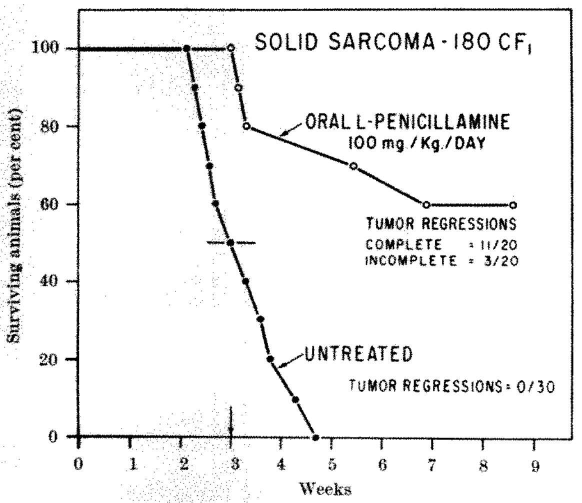

Fig. 1. Effect of oral L-penicillamine on survival of solid sarcoma-180-implanted mice maintained on complete diet. L-Penicillamine administered via drinking-water (0·5 mg/ml.) and given *ad libitum* to about 100 mg/kg/day

Exps. 2, 3 and 4 with sarcoma-180-bearing mice showed a similar life-prolonging effect of L-penicillamine (Table 2). In previous experiments, which had lasted only 14 days each, the daily subcutaneous injection of L-penicillamine had caused retardation of the development of solid sarcoma-180 but failed to reduce the size of tumour masses already formed[1]. In retrospect, we now attribute this to the short duration of treatment. Very few compounds which inhibit tumour growth cause *regression* of fully developed tumours. For example, only 6-mercaptopurine, some related antimetabolites[2,3] and pyridoxine-deficient diet[4] have been found to induce true regressions of already established sarcoma-180. The prolongation of life and regression of solid sarcoma-180 tumours in CF_1 mice, given prolonged oral therapy with L-penicillamine while being maintained on complete diet, assumes considerable importance. L-Penicillamine-induced tumour regression may be due to: (1) the blocking ability of L-penicillamine in preventing the developing tumour from obtaining sufficient vitamin B_6 needed for B_6-dependent cellular processes; (2) L-penicillamine-induced alteration of cellular metabolism; (3) immunological response of the host toward L-penicillamine-treated tumour tissue; (4) to some combination of these factors. Some support for the idea of immunological response of the host is found in the information that cortisone reduced the number of tumour regressions caused by 6-mercaptopurine without affecting retardation of tumour growth[5].

Effect of oral L-penicillamine on weight gain of tumour-free normal CF_1 mice fed with complete and pyridoxine-deficient diets. The effect on normal 22-g tumour-free CF_1 male Swiss mice of prolonged maintenance on complete and pyridoxine-deficient diets with and without oral L-penicillamine is shown in Table 3. Normal mice maintained on a complete diet gained 40 per cent body-weight after 30 days and 66 per cent in 60 days, without mortality. The addition of L-penicillamine to the drinking-water reduced this weight gain to 31 and 37 per cent over the same periods of time and the mice exhibited slightly roughened coats with 10 per cent mortality within the 60-day period. Maintenance of pyridoxine-deficient diet alone caused marked roughening of coats, but gain in weight did occur, albeit at a slower rate than with complete diet, and there was no mortality. The addition of L-penicillamine to the drinking water of the group maintained on pyridoxine-deficient diet retarded their normal weight gain still further within the first 30 days, but there was no actual weight loss. It was only during the second 30 days of oral L-penicillamine therapy with pyridoxine-deficient diet that a 15 per cent loss in body-weight and 20 per cent mortality occurred. This was attributed to the reinforcing action of L-penicillamine on the vitamin deficiency induced by pyridoxine-deficient diet. Baseline data demonstrate that within the first 30 days maintenance on pyridoxine-deficient diet, with or without daily oral treatment with L-penicillamine, does not cause either weight loss or mortality in CF_1 mice.

Table 3. EFFECT OF ORAL L-PENICILLAMINE AND PYRIDOXINE-DEFICIENT DIET ON BODY-WEIGHT OF TUMOUR-FREE NORMAL MICE

Diet	L-Penicillamine mg/kg/day	Average body-weight (g) Initial	14 days	30 days	60 days	Mortality

,, ,,	100*	22·0	28·0	29·0	31·3	1/10
Pyridoxine-deficient diet	0	22·0	24·0	26·0	28·0	0/10
,, ,,	100*	22·0	23·0	24·0	18·7	2/10

* Added to drinking water at conc. of 0·5 mg/ml. Average daily fluid intake 4–5 ml./mouse.

Effect of oral L-*penicillamine on ascitic sarcoma-180.* Maintenance of ascitic sarcoma-180-bearing mice on pyridoxine-deficient diet caused inhibition of tumour development and more so when L-penicillamine was added to the drinking-water (Table 4). These mice had received ascitic cells by intraperitoneal route. Median survival time was not prolonged significantly by either pyridoxine-deficient diet, L-penicillamine, or a combination of both.

Table 4. EFFECT OF ORAL L-PENICILLAMINE AND PYRIDOXINE-DEFICIENT DIET ON ASCITIC SARCOMA-180 IN CF_1 WHITE SWISS MICE

Diet	L-Penicillamine (mg/kg/day)	Average body-weight* (g)	Ascitic tumour inhibition	Median survival time (days)
Complete diet	0	31·6	—	10
,, ,,	100†	26·0	±	12·5
Pyridoxine-deficient diet	0	23·7	+	11·5

* 8 days after intraperitoneal injection 1×10^6 ascitic S-180 cells. Initial average weight 20 g.

† Treatment started 24 h after tumour implantation, and given daily for 7 days. Drinking-water contained 0·5 mg L-penicillamine/ml. Each mouse consumed approx. 2 mg penicillamine/day (100 mg/kg).

Tumour retarding effect of L-*penicillamine on solid sarcoma-180 when administered by different routes.* Twenty-four hours after subcutaneous implantation of standard dose of ascitic sarcoma-180 in CF_1 mice, treatment with L-penicillamine was commenced via different routes, and continued daily for 7 days (Table 5). Single daily doses were administered subcutaneously, intraperitoneally and by stomach intubation. Continuous oral therapy was provided by addition of L-penicillamine to the drinking-water. L-Penicillamine proved to be equally as active as a tumour-retarding agent by all routes of administration, and the tumour-retarding effect was demonstrable at 25, 50 and 100 mg/kg daily dose-levels. Subcutaneous injection of 200 mg L-penicillamine/kg/day was toxic. More detailed effects of subcutaneous therapy of L-penicillamine on sarcoma-180 may be found in a previous publication[1]. Addition of L-penicillamine to the drinking-water proved to be the simplest method of administering the drug. The higher mortality in mice intubated with L-penicillamine as a single daily dose was attributed, in part, to instrumentation.

MODE OF MULTIPLICATION OF *Theileria* IN CULTURES OF BOVINE LYMPHOCYTIC CELLS

By DR. LOTTE HULLIGER, DR. J. K. H. WILDE, C. G. D. BROWN and MISS LESLIE TURNER

Wellcome Research Laboratory (East Africa), Kabete, Kenya

SINCE the early work on East Coast fever by Theiler[1], Gonder[2], Koch[3] and Meyer[4], no conclusive evidence has been brought forward to establish the mode of infection and multiplication of *Theileria parva* in the bovine host. It was assumed by the early workers, particularly by Gonder[2], that the parasite, after infecting lymphocytes, multiplied by schizogony, the particles of the schizonts breaking up into merozoites which then infected other lymphocytes. Gonder believed the final stages of schizogony to be the production of gamonts which broke up into individual particles and then infected red cells. Cowdry and Danks[5] and Neitz[6] subscribed to this view. Reichenow[7], however, while agreeing with the theory of further infection of lymphocytes by merozoites produced by division of the original parasites, considered that this division was by binary fission and not by schizogony.

Prolonged cultivation of *T. parva* and *T. annulata* has provided an opportunity for detailed examination of the multiplication of the parasite *in vitro*.

Multiplication of *T. annulata* in tissue culture using spleen explants in plasma clot has been described by Tsur[8] and Brocklesby and Hawking[10]. Initial multiplication and survival of *T. parva* over a period of 15 days in tissue cultures were described by Tsur *et al.*[9] and confirmed by Brocklesby and Hawking[9]. Mass cultivation of *T. annulata* has been carried out by Tsur and Adler[11].

In this Laboratory mass cultivation of *T. annulata* has been successful over a period of four months and *T. parva* has been cultivated similarly for up to three months. During this cultivation, no signs of cytopathogenic activity by the parasite have been detected.

Evidence has been obtained to support the concept that distribution of *Theileria* into both daughter cells during mitotic division of the host cell is responsible for the increase in numbers of infected cells.

Terminology. The terminology used to describe the manifestations of the various parts of the life-cycle of the Theileridae is confusing and may be misleading. The forms of the parasite found in cells of the lymphatic system are often described as schizonts of two types: the macroschizonts and the microschizonts. We are not satisfied that division of the parasite at this stage is by schizogony and so prefer to adopt a less misleading terminology. For the macroschizont, sometimes called the 'agamont' or 'Koch's body', we use the term 'theilerial body'. By this is understood the close association of chromatin particles enveloped in cytoplasm which is characteristic of the early stages of the patent disease in the bovine host. For the individual particles of chromatin which make up this body we prefer the term 'theilerial particles'.

The so-called microschizont or gamont which appears in the later stages of the disease is made up of small, more compact particles of chromatin aggregated in larger numbers. Whereas these appear readily to break up into what may be termed 'merozoites', those stages described as 'theilerial bodies' here do not. In the series of tissue cultures described in this article, no gamont-like bodies appeared and, therefore, the terms 'theilerial body' and 'theilerial particle' refer only to the so-called agamont and its constituent particles.

Observations were made on *Theileria*-infected cells growing in monolayer. The cells had been isolated from bovine spleen, lymph nodes or blood from *Theileria*-infected animals and grown in association with a cell line of baby hamster kidney (B.H.K.), isolated by Macpherson and Stoker[12].

(*A*) *Chromosomal analysis of host cells.* Chromosomal analysis was used to determine whether the *Theileria*-infected cells were bovine or hamster. Cultures were incubated with colchicine (10^{-7} g/ml.) for 6 h, then treated for 5 min in hypotonic solution, fixed and stained with Giemsa. Bovine cells are readily distinguished from hamster cells on the basis of chromosome number and morphology. The hamster chromosomes are acro- or meta-centric, usually numbering 44 and rarely 88. The bovine chromosomes are smaller, rod-shaped and their number is 60. The centromere is situated at one end of the chromosome (telocentric) in all except one pair.

Slide preparations of such cultures showed large numbers of cells in mitosis. Theilerial particles could be recognized as pale red particles in between the chromosomes. They were found only in bovine cells and not in hamster cells; 98–100 per cent bovine cells were infected with *Theileria* in established cultures.

(*B*) *Observations on mitotic division of* Theileria-*infected cells.* Cell suspensions were fixed immediately after centrifugation to obtain all phases of mitotic division. Drop preparations were stained with Giemsa. Many mitotic figures were examined for the distribution of theilerial particles. Representative examples are shown in Fig. 1.

Prophase: Theilerial particles were found in the cytoplasm between the chromosomes.

Metaphase: The parasite was found almost invariably in close association with the chromosomes as a distinct theilerial body, the most typical location being in between them, thus disturbing the symmetry of the equatorial plate.

Anaphase: The particles were aligned in one or two, rarely more, threads along the fibrils of the spindle; in each of the threads the particles were associated in a strand of coherent cytoplasm.

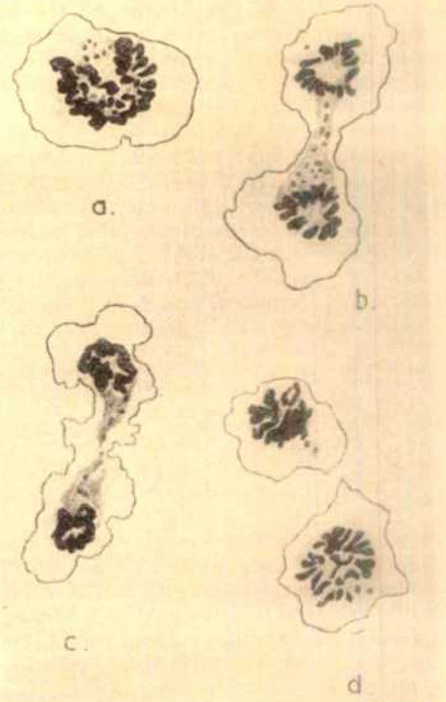

Fig. 1. Stages in the Division of *Theileria*-infected cells. (*a*) Metaphase with theilerial body; (*b*) telophase with one strand; (*c*) telophase, theilerial body separating into two; (*d*) reconstruction, both daughter cells with theilerial body

Telophase: The thread-like theilerial bodies were stretched by the dividing cell but still existed as one unit. In a few cases the thread was disrupted in one place, generally near the middle.

Reconstruction: Complete separation of the cells and the theilerial bodies had taken place.

Such a distribution of theilerial particles into both daughter cells was seen in 146 out of the 147 late mitotic phases observed and only on one occasion was a pair seen in which one of the daughter cells contained no parasite.

(*C*) *Number of theilerial particles per cell.* The number of theilerial particles per cell was counted in 100 infected cells in preparations made over a period of three months from one line of *T. annulata* isolated on Sept. 12, 1963*. The data when plotted gave a typical Poisson distribution. The averages and standard deviations are given in Table 1. In the last column the percentages of cells with more than one theilerial body are listed.

Table 1. NUMBER OF THEILERIAL PARTICLES PER CELL DURING PROLONGED CULTIVATION. DATE OF ISOLATION SEPT. 12, 1963

Days of cultivation	Theilerial particles/cell Average	*S.D.*	% cells with more than one theilerial body
28	14	12	6·5
35	16	11	8·0
54	17	17	9·0
77	15	10	14·5
95	14	8	6·5
117	14	10	8·5

During the three months of observations the average numbers of theilerial particles was found to be constant within the limits of 14 and 17. The number of cells containing more than one body varied from 6·5 to 14·5 per cent but no progressive increase occurred during this period.

(*D*) *Effect of prolonged exposure to colchicine.* Preliminary experiments had suggested that colchicine, at

* The Tova strain of *T. annulata* kindly provided by Dr. Tsur of Israel and which had been serially passaged by blood inoculation in calves.

concentrations of not more than 10^{-7} g/ml., while inhibiting the mitotic division of the bovine host cells did not prevent the multiplication of theilerial particles.

Colchicine in a final concentration of 3×10^{-8} g/ml. was added to cultures of *Theileria*-infected cells. Samples were taken at 0, 24 and 48 h. Control cultures without colchicine were examined at the same times. Theilerial particles in each cell were counted.

The results are given in Table 2. After 24 h the average number of particles per cell in a control culture was 17·6 and in a colchicine-treated culture 38·8. After 48 h the average rose in the latter to 111·2, with a very wide distribution; signs of a toxic effect on the host cells, such as giant cell formation and foamy changes of cytoplasm, could be observed.

Table 2. EFFECT OF COLCHICINE ON NUMBER OF THEILERIAL PARTICLES PER CELL

Colchicine conc.: 10^{-8} g/ml.

Time (h)	Colchicine		Control cultures	
	Average	*S.D.*	Average	*S.D.*
0	—	—	14	11
24	39	17	18	11
48	115	65	16	14

Discussion. *T. annulata* and *T. parva* were cultivated *in vitro* on a large scale in bovine cells isolated from lymphatic tissue in association with B.H.K. cells. Chromosomal analysis showed that the host cells of *Theileria* were bovine cells and that of these cells in established cultures 98–100 per cent were infected with *Theileria*. Massive propagation of *Theileria*-infected cells in tissue culture was maintained, however, for months. During the continued multiplication of infected cells, distribution of theilerial particles into both daughter cells regularly took place. The theilerial body was associated with the mitotically dividing cell in such a way that it generally formed one thread attached to the spindle fibres and this chain was pulled apart in late mitosis. In a number of cells more than one thread was aligned along the spindle fibres. The percentage of such mitotic cells was in the same range as the percentage of resting cells infected with more than one theilerial body.

Reichenow[7] described the foregoing mechanism of distribution of theilerial particles into both daughter cells during mitosis in infected cattle, but he assumed this to be a peculiarity of a few cells only. On this observation he based the assumption that intracellular theilerial bodies were agglomerations of single organisms which could dissociate freely during host cell division.

We have so far not found any signs of such dissociation in their cultures. In these investigations, the mechanism described here was observed in 98 per cent of all mitotic figures, and since there were scarcely any uninfected bovine cells, it has to be assumed that, in these tissue cultures at least, a clone of infected lymphoid cells was produced and that theilerial particles multiplied intracellularly. Disintegration of infected lymphoid cells and the release of single theilerial particles (merozoites) and infection of new cells were not observed.

The rate of multiplication of theilerial particles seemed to be in balance with the rate of multiplication of their host cells, as over several months the average number of particles per cell was constant between 14 and 17. Additional evidence was obtained from the experiments with colchicine. The single theilerial particles seemed to divide into two. Twin particles closely associated with one another within the theilerial body could be observed in the resting cell and during all stages of mitosis. All the evidence was against simultaneous division of the particles within one cell, nor did there exist evidence of the division of theilerial particles synchronously with the mitotic division of their host cell.

In the *Theileria*-infected animal the very rapid enlargement of lymph nodes has been shown to be due mainly to multiple mitotic division[13]. This suggests that *Theileria* might stimulate the host cells to divide at an increased rate, possibly by means of an association with the Golgi apparatus.

Observations made on many thousands of lymph-node biopsy smears from animals infected with *T. parva* have failed to produce convincing evidence that multiplication of the parasites in their lymphocytic stage takes place by the infection of fresh lymph-node cells by merozoites liberated from the disintegrated theilerial bodies. On the other hand, we have often observed cells in which theilerial bodies were associated with the mitotic division of the host cell in the same way as described here for tissue culture. Further work is, however, necessary to elucidate the whole picture of the life-cycle of *Theileria* in the bovine host.

MAST CELLS AND HYALURONIC ACID IN THE BOVINE ENDOMETRIUM

By DR. I. N. LIKAR, DR. LYDIA J. LIKAR and DR. R. W. ROBINSON

Research Laboratory, The Memorial Hospital, Worcester, Mass.

RECENT literature concerning mast cells is abundant but somewhat confusing[1–3]. The pluri-potential functions of mast cells in the dynamics of the connective tissue seem to be related to the chemical substances heparin, histamine, hyaluronic acid and serotonin. It appears that sufficient data are available to confirm the presence of heparin and histamine in the mast cell granules[3], but as regards serotonin and hyaluronic acid the question is not settled[1,2]. Whether these substances are merely stored in the mast cells or stored and synthesized is not yet clear[2,3].

In previous work[4], the acid mucopolysaccharides of the bovine uterine wall were located by histochemical techniques, and it was found that the colour intensity of the staining reaction of acid mucopolysaccharides (AMPs) varied during the sexual cycle. A biochemical investigation indicated 3 fractions of acid mucopolysaccharides present in the bovine uterine wall: fraction 1, hyaluronate; fraction 2, chondroitin sulphates and heparin monosulphate; and fraction 3, heparin. Inspection of the levels of fractions 1, 2 and 3 showed that the greatest variations occurred in the titres of fraction 1 (hyaluronate). The

Figs. 1–4. Cross-sections of bovine endometrium at different stages of the sexual cycle, stained with toluidine blue for mast cells (all × c. 225)

Fig. 1. Few mast cells; metœstrus

Fig. 2. Fair number of mast cells; diœstrus

Fig. 3. Many mast cells; proœstrus

Fig. 4. Many mast cells and evidence of degranulation; œstrus

average value of fraction 1 in pro-œstrus–œstrus was 881 μg/g, while in metœstrus–diœstrus it was 426 μg/g, the difference being approximately 50 per cent. The average values of fraction 2 (616 and 615 μg/g for pro-œstrus–œstrus and metœstrus–diœstrus, respectively) and fraction 3 (130 and 155 μg/g at different stages of the sexual cycle) did not show significant variations. However, histological observation of the presence of mast cells in the bovine uterine wall during the sexual cycle demonstrated cyclic changes, especially in the endometrium.

The purpose of the work recorded here was to investigate the relationship between the mast cells and the hyaluronic acid in the bovine endometrial stroma with particular reference to the sexual cycle.

Twenty fresh uteri with ovaries were collected from abattoirs with all necessary preventive measures. After the gross examination of the ovaries and uteri to establish approximately the stage of the sexual cycle[4], samples of ovaries and uteri were fixed in 10 per cent formalin with cetyl pyridinium chloride[11] (at room temperature) or in 96 per cent ethanol (at − 20° C). Uniform sampling of a piece of uterus-horn 1 cm from the bifurcation was utilized. The endometrium was separated from the myometrium and perimetrium and afterwards preserved in acetone at − 20° C for biochemical examination. For histochemical examination, paraffin sections were cut at 6μ and stained by Hale's method (*IC*) for acid mucopolysaccharides as modified by Rinehart and Abul'Haj[6], periodic acid–Schiff's method (PAS) according to McManus[7] and toluidine blue method (*TB*) at *p*H 4·1 and *p*H 1·5 as described by Hayashi *et al.*[8] Routine hæmatoxylin and eosin stains were used for definite verification of the stage of the sexual cycle, which was previously determined only approximately by gross examination. The mast cells were stained with toluidine blue pH 3 in 70 per cent ethanol. The total AMP and hyaluronic acid in a 2-g biopsy were determined biochemically by the method of Schiller *et al.*[5,9].

Histological examination of the mast cells confirmed our previous findings[4] that after œstrus the number of mast cells decreased rapidly and in the middle of metœstrus reached its lowest peak. During this stage only a few scattered mast cells were observed under the lining epithelia (Fig. 1). Later the number slowly increased, and mast cells with more distinct granules were noted (Fig. 2). In diœstrus the number was increased further and the mast cells were found throughout the endometrial stroma, particularly under the lining epithelia. In pro-œstrus they were concentrated more distinctly beneath the lining epithelia (Fig. 3) and around the uterine glands. The mast cells in this stage were stained more intensively with toluidine blue and some were also *IC*- and PAS-positive. At the end of pro-œstrus or at the beginning of œstrus degranulation of mast cells was observed. Degranulation was more noticeable during the end of œstrus and the mast cells were stained less distinctly (Fig. 4). The number of mast cells then decreased rapidly as described before (Tables 1 and 2).

The histochemical investigation located the AMPs in the endometrial stroma, particularly beneath the lining epithelia and much less around the uterine glands and in or around the walls of the uterine blood vessels (areas where the mast cells were present). The colour intensity varied at different stages of the sexual cycle (Table 1).

Table 1

Stage of the sexual cycle	Endometrial stroma PAS	*IC*	*TB* (pH 4·1)	Mast cells
Metœstrus	±	−	−	+
Diœstrus	±	±	±	+ +
Pro-œstrus	+	+	+	+ + +
Œstrus	+ +	+ +	+ +	+ + +

Histochemical evaluation: −, negative; ±, in traces; +, slightly positive; + +, strongly positive.

Incidence of mast cells: +, low incidence; + +, medium incidence; + + +, high incidence.

When sections were stained with *TB* at pH 1·5 the AMPs were always stained orthochromatically. This finding and PAS staining reaction in the same areas indicated also the presence of unsulphated acid mucopolysaccharides in the bovine endometrial stroma[6-8,10].

Biochemical examination of endometrium demonstrated that hyaluronic acid varied greatly in value during the sexual cycle (Table 2). These variations were parallel with an increase or decrease of mast cells, with the colour intensity of the histochemical determination and with the value of the total amount of AMPs (Fig. 5). The possibility, therefore, exists that AMPs and the mast cells in the bovine endometrium are regulated by the hormones of the sexual cycle.

Table 2

Animal	Stage of the sexual cycle	Mast cells	Hyaluronic acid (μg/g)	Total amount of acid mucopolysaccharides (μg/g)
1	Metœstrus	+	300	840
2	,,	±	360	880
3	,,	+	340	1,000
4	Diœstrus	+ +	352	1,300
5	,,	+ +	412	1,460
6	,,	+ +	550	1,500
7	Pro-œstrus	+ + +	529	1,700
8	,,	+ + +	503	1,630
9	,,	+ + +	675	1,670
10	Œstrus	+ + + +	812	1,600
11	,,	+ + + +	839	1,850
12	,,	+ + +	790	1,740

Incidence of mast cells in a microscopic field (objective 16): ±, less than 3; +, 3–10; + +, 10–30; + + +, 30–50; + + + +, 50 or more.

The different staining reactions of mast cells toward *IC*, PAS and *TB* indicate that mast cells are a heterogeneous population in the connective tissue. The orientation and number of mast cells have further significance from the point of view of available AMPs. Where there is a need for AMPs and the tissue does not contain sufficient amounts of ground substance of fibroblasts there is normally a higher number of mast cells present[2]. It would appear that AMPs are of local origin, and in this investigation a significant increase of fibroblasts was not noted by histological observation. While mast cells are not the only source nor even a significantly voluminous source of AMPs, they are important in the metabolism of AMPs[2]. Mast cells seem to be capable of both storage and/or synthesis, and of unloading the contents almost instantly, in contrast with fibroblasts and epithelial cells, which commonly produce a small continuous supply of AMPs during a longer period of time[2,3].

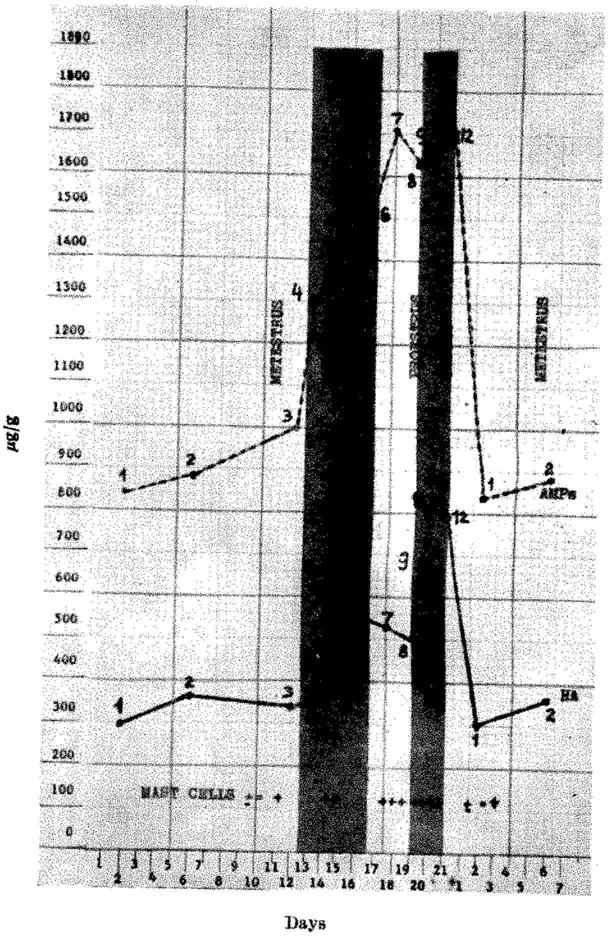

Fig. 5. Average values for hyaluronic acid (HA) and acid mucopolysaccharides (AMPs) (μg/g) and mast cells in bovine endometrium at different stages of the sexual cycle. ±, less than 3 mast cells in a microscopic field (objective 16); +, 3–10 mast cells; + +, 10–30 mast cells; + + +, 30–50 mast cells; + + + +, more than 50 mast cells

The results of this investigation support the concept that mast cells participate in the production of hyaluronic acid. These findings are in accord with Asboe-Hansen[1], who suggested that there exists a definite relationship between the mast cells and hyaluronic acid content of the tissue. In the present work, biochemical, histochemical and histological investigations of the bovine endometrial stroma demonstrate that the values of hyaluronic acid and the total amount of acid mucopolysaccharides are parallel with the numerical changes of the mast cells at different stages of the sexual cycle. Different staining reactions of mast cells at different stages of the sexual cycle suggest that the content of granules is not the same in all mast cells. The localization of mast cells, histochemical staining reactions for AMPs in these areas, and biochemical values indicate that mast cells might share in the production of hyaluronic acid in the bovine endometrial stroma.

IMMUNOLOGICAL PARALYSIS INDUCED IN ADULT RABBITS BY SMALL AMOUNTS OF A PROTEIN ANTIGEN

By DR. D. W. DRESSER and DR. G. GOWLAND

National Institute for Medical Research, Mill Hill,
London, N.W.7

SPECIFIC immunological paralysis (tolerance, unresponsiveness) was induced in adult mice after the injection of small amounts of heterologous γ-globulin[1], an observation which has since been confirmed[2]. The earlier work suggested that the adjuvanticity of a protein antigen had an important bearing on whether or not small amounts of this antigen would induce a specific state of paralysis in adult mice. 'Adjuvanticity' has been described as that property of an antigen which leads to its recognition as being foreign or denatured[3]. Formerly it could have been argued that this phenomenon was not a general one but was restricted to bovine γ-globulin in adult *CBA* mice.

It is now known that several other mammalian γ-globulins will paralyse *CBA* and other strains of mice[4]; that *CBA* mice may have a considerable degree of paralysis induced in them by small amounts of bovine serum albumin[5]; and finally, that guinea pigs can be paralysed by bovine γ-globulin injected via the mesenteric vein[6]. It now seems more likely that the induction of paralysis by small amounts of a protein antigen lacking adjuvanticity (non-immunogenic ?) may be a general phenomenon. Paralysis to proteins possessing their own adjuvanticity, that is, proteins sufficiently foreign to initiate an immune response without the addition of an artificial adjuvant, can only be achieved by the injection of massive doses of antigen into adults (antigen overloading paralysis) or by the injection of smaller amounts of antigen into neonatal animals before the onset of immunological maturity (tolerance)[7].

The object of our experiments was to attempt to induce immunological paralysis in adult rabbits using small amounts of a protein antigen. The rabbit is generally recognized as a good producer of antisera to a wide range of proteins, including denatured rabbit γ-globulin. Therefore, we thought that a satisfactory demonstration of this type of immunological paralysis in rabbits would greatly strengthen the argument that the phenomenon was a general one and has an important bearing on the basic mechanism involved in the induction of immunological paralysis (tolerance). The classical experiments of Glenny and Hopkins[8], carried out more than forty years ago, led to the use of equine γ-globulin in some preliminary experiments. As the paralysis achieved in these preliminary experiments with this antigen was marginal indeed, we decided to use leporine γ-globulin (from *Lepus europaeus occidentalis* De Winton, the lowland hare) on the grounds that closer phylogenetic relationship might give a better chance of success. The results show that a convincing degree of paralysis was obtained with this antigen.

The rabbits used in the preliminary experiments were sandy lops (from a Southern California commercial dealer) and those in the main experiments Himalayans (from the closed colony maintained at the National Institute for Medical Research). The antigens were equine γ-globulin (EGG; Pentex Inc., Batch No. *E* 24) and leporine γ-globulin (LGG) prepared from hare serum by ion-exchange chromatography on DEAE–'Sephadex, *A*–50' coarse, using a stepwise molarity gradient. 110 ml. of hare serum was dialysed against 0·0175 M *tris*/phosphate buffer *p*H 8·0 and the DEAE was equilibrated against the same strength buffer. As the amount of protein eluted from this column (5 × 75 cm) with this buffer proved to be too small to use (it appeared to be 'pure' Y_{ss} globulin), 0·2 M buffer (0·05 M *tris*/phosphate + 0·15 M sodium chloride) was used for the next elution step. A considerable amount of protein was eluted from the column, which, after concentration by pressure dialysis, was shown by immunoelectrophoresis to contain considerable amounts of a Y_{ss}-like protein and a small amount of a Y_{1A}-like protein. Both EGG and LGG were centrifuged at 25,000–30,000*g* prior to intravenous injection. EGG was labelled with iodine-131 by the method of Wormal[1] (EGG*) and the LGG by the more satisfactory ICI method of McFarlane[9] (LGG*); both proteins received less than one atom of iodine per molecule. Rabbits injected with iodine-labelled protein were given water containing 100 mg sodium iodide/l. during the elimination of the antigen. Rabbits were bled from the marginal ear vein into tared tubes and the counts per g of whole blood expressed as a percentage of the amount of antigen in the circulation 24 h after intravenous injection (assuming that most, if not all, the label was still attached to the antigen).

Fig. 1 illustrates the results obtained with EGG as the antigen in the preliminary experiments. It can be seen that:

(*A*) There is a marked primary response to an intravenous injection of 50 mg of EGG*. This is probably of importance when compared with the lack of response to a similar injection of LGG*.

(*B*) There is an easily detectable difference between the primary response and a secondary response after prior immunization with complete Freund's adjuvant containing 100 mg EGG (Freund's/EGG).

(*C*) Rabbits injected intravenously with 100 mg centrifuged EGG 8 days before challenge with Freund's/EGG show a response intermediate between the primary and secondary responses and in most cases significantly less than the secondary response control.

(*D*) Two rabbits given the same treatment as (*C*), but also injected intravenously with 10 mg EGG 17 days earlier, showed an even greater elimination response than secondary response controls. An equivalence test, however, showed them to have somewhat less circulating antibody. It is clear from these experiments that EGG contains its own adjuvanticity in rabbits. The small number of rabbits apparently paralysed by Glenny and

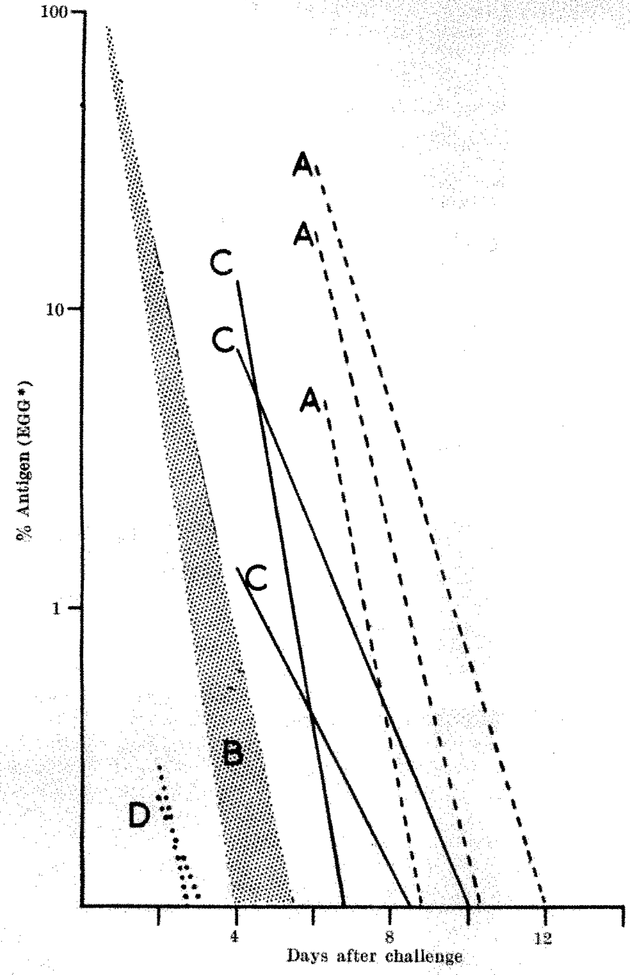

Fig. 1. Simplified graphs of the elimination of EGG*. Key to groups *A*, *B*, *C* and *D* in the text

Hopkins[8] may easily have been due to a combination of genetic differences in those rabbits with a low level of overloading paralysis.

In the experiments using LGG several rabbits were tested more than once with LGG*. Table 1 lists the animals used, the nature and dates of any treatment given and, where relevant, the approximate nature of the antigen-elimination curve with the approximate half-life of the antigen in the circulation during elimination. Fig. 2 illustrates the elimination of LGG* from the circulation of: (*a*) normal rabbits, Nos. 1 (injected twice, curves 1*a* and *b*), 2, 3; (*b*) rabbits previously injected with alum-precipitated LGG admixed with *Bordetella pertussis*, Nos. 4, 5; (*c*) rabbits previously given a series of injections of *Proteus vulgaris* coated with LGG (in the form of hare antibody prepared against this organism), Nos. 8, 9; (*d*) rabbits previously injected with Freund's/LGG, Nos. 6, 7, 10, 11. Only those animals previously injected with the antigen emulsified in complete Freund's adjuvant showed immune elimination of LGG when tested. The half-life of LGG* in normal animals varied between 2·5 and 3·9 days with an average of 3·3 days.

Fig. 3 illustrates the effect of injecting LGG as a solution prior to immunization with Freund's/LGG (Nos. 1, 2, 3, 12, 13, 14 and 15). The results show that a considerable degree of paralysis was obtained even when the intravenous injection of 16 mg LGG was as long as 3 months before challenge with Freund's/LGG.

Serial dilutions of serum samples obtained one week after the end of elimination experiments were tested against a 1 per cent solution of LGG in Ouchterlony gel-diffusion plates. These showed that rabbits 6, 7, 10 and 11, which showed immune elimination of LGG*, had precipitin titres of from 1/8 to 1/16; rabbits with weak immune eliminations or non-immune eliminations had no detectable antibody to LGG in their serum.

Although on a small scale with regard to numbers of animals our results are compatible with conclusions drawn from earlier work with mice[1], where it was concluded that there was a progressive loss of paralysis after a given dose of paralytogen; that with increased doses of paralytogen the state of paralysis would be longer lasting (Table 1, rabbit 1); and that further injections of paralytogen before a state of paralysis had been lost could prevent

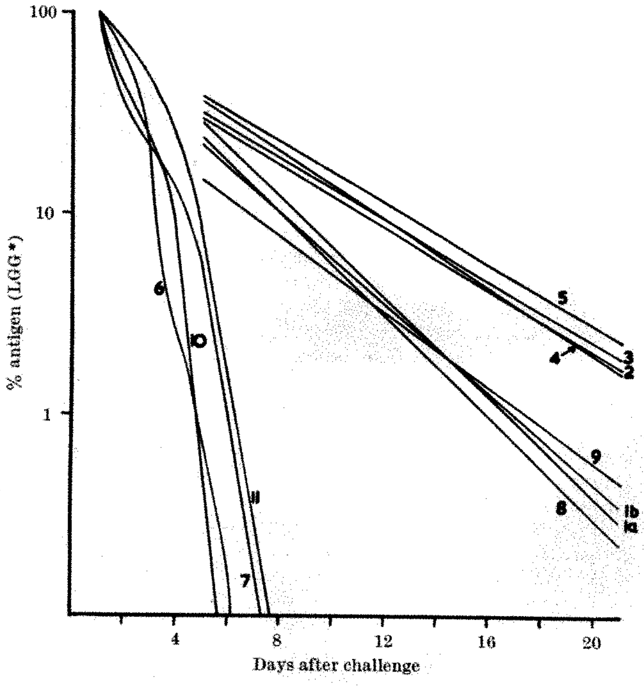

Fig. 2. Graph of the elimination of LGG*. Rabbits 1, 2, 3, 4, 5, 8 and 9 failing to show an immune response. Rabbits 6, 7, 10 and 11 showing a secondary response after prior challenge with Freund's/LGG

* Estimated from day 3 to 5 in immune animals and from 5 to 15 in all others.

a break from paralysis (for example, Table 1, rabbits 2 and 3).

Further comparisons between protein-induced paralysis in rabbits and mice now seem possible. The minimum dose of bovine γ-globulin (BGG) capable of inducing a reasonably complete degree of paralysis in adult *CBA* mice is 20–200 μg, although as little as 2 μg gives a measurable effect. As the mice used weighed about 20 g, the minimum effective dose was about 10 mg/kg body-weight. For LGG in rabbits a considerable effect was seen 3 months after a dose of 16 mg given to animals weighing 900–1,100 g. It has been estimated that 10^{11}–10^{13} molecules of BGG must remain in the mouse for a state of paralysis to be maintained[10]. A similar calculation based on the half-life of antigen in the circulation can be made for rabbits injected with LGG. This gives a figure of 10^8–10^9 molecules required to maintain a degree of immunological paralysis in a rabbit, that is, about 100 times less than the number of molecules apparently required to maintain paralysis in the mouse. This does not take into account the difference in size between the two animals and presumably a difference in the number of cells requiring antigen to remain in a state of paralysis. Such differences would increase the discrepancy between the two figures. We think that this discrepancy illustrates that the half-life of antigen in the circulation is not a good measure of the half-life of antigen in the animal as a whole. If taken at face value the figures would imply that intracellular antigen is destroyed at a slower rate than the same antigen is removed from the circulation; much more slowly in the case of LGG in rabbits (half-life in the circulation 3·3 days) than in the case of BGG in *CBA* mice (half-life in the circulation 6·5 days). Calculations of the number of molecules of antigen persisting in relation to a state of paralysis, based on half-lives of antigen in the circulation, probably have little significance.

There is a fundamental difference between the immunological response to EGG and many other proteins and the response to LGG in rabbits; also, between serum albumins and mammalian γ-globulins in mice and possibly guinea pigs. In each case the former proteins can elicit an immune response without any aid from adjuvants, whereas the latter rarely elicit an immune response on their own and, in fact, elicit a specific state of immunological paralysis. An immune response to these paralytogens can be stimulated in normal animals by the use of an adjuvant, for example, Freund's adjuvant containing the appropriate antigen. The first response of an animal to injected material may not be an immunological one, but a failure or non-failure to recognize this material as foreign as was originally proposed by Burnet and Fenner[11]. If it is recognized as foreign the material is fed into a pathway which can lead to a specific immune response, while failure to recognize it as foreign (either because it is not foreign or because it is sufficiently closely related structurally to self-components to be mistaken for self) will fail to open up the immune pathway. Several things could be implied from this postulated mechanism. First, that the specificity of the mechanism for the recognition of self is not as accurate as the specificity of the immunological paralysis mechanism. Secondly, that there is no reason to think at present that unrecognized foreign material is not metabolized in the same way as self-components. The catabolic pathway must therefore give access to the paralysis mechanism, and it would seem that the mechanism of induction and maintenance of paralysis are not basically different. Thirdly, experiments with adjuvants indicate that the immune pathway can be opened up non-specifically, which would imply that the mechanism of immunological paralysis must operate to prevent general auto-immunity. Exceptions to this would be lens protein, nervous tissue and perhaps thyroid, where, in some cases, a lack of adjuvanticity together with a lack of ready access by antibody-forming cells prevents auto-immunity to them and, almost by definition, the failure to induce or at least maintain any state of paralysis (tolerance) to these tissues.

Antibody production to many protein antigens can be suppressed in adult animals by the repeated injection of large amounts of antigen (antigen overloading paralysis), for example, 0·5 mg/g body-weight/day for several weeks[12]. This high level of antigen seems to be necessary to suppress antibody production in cells already induced or being induced to produce antibody. With LGG in rabbits and γ-globulins in mice the amount of antigen required to elicit paralysis and that required to stimulate immunity (aided by an adjuvant) seem to be of the same order of magnitude. This clearly indicates that paralysis is not a by-product of over-saturation by antigen (unless the antigen is recognized as foreign, and the induction of immunity ensues in some cells), but, as was previously suggested, is a result of the failure of one of the steps in the pathway to an immune response.

Recent investigations of rabbit γ-globulin allotypes[13] have shown that antigenic γ-globulins of maternal origin may be found for a time in the circulation of young rabbits. When the young are genotypically different from their mothers it seems reasonable to expect that immunological paralysis to the foreign allotypes will be induced and maintained for a time, although so far as we know this has not yet been tested.

The preliminary experiments were carried out by one of us (D. W. D.) in the Division of Biology, California Institute of Technology, and thanks are due to Prof. R. D. Owen. We also thank Dr. J. H. Humphrey for advice and Miss Jeanette Dilley and Mr. D. Wilson for their assistance.

FŒTAL EXCLUSION BY TRANSUTERINE LIGATION OF THE UMBILICAL CORD

By DR. DAVID LEHR, MARILYN KRUKOWSKI and RITA COLÓN

Department of Physiology and Pharmacology, New York Medical College,
Flower and Fifth Avenue Hospitals, New York

IN the course of investigations in the albino rat on the mechanism of protection by advanced pregnancy against parathyroid hormone-induced cardiorenal necrosis and calcification[1], it appeared of interest to explore the effects of the placentas in the absence of the fœtuses. Removal of the fœtuses was carried out by Caesarean section which required individual surgical entry into all uterine beads. It was noted that even with most careful and gentle handling, interference with the integrity of the surviving part of the placenta was unavoidable, since removal of the fœtus and loss of amniotic fluid destroyed the physiological tension of the amniotic sac and created a void which could not be readily abolished by contraction of the extremely thinned-out myometrium. Although most placentas survived until term in fairly good condition when fœtal extirpation was carried out on the 19th day of pregnancy, the decrease in protection against parathyroid hormone poisoning was difficult to interpret. It could have been caused by the removal of a fœtal factor. But it might also have been caused by diminution of a maternal protective mechanism, due either to placental damage or hormonal alterations resulting from removal of the fœtus or the premature loss of uterine distension[1].

To avoid these pitfalls, a more physiological means of fœtal exclusion was sought. This led to the development of a simple procedure consisting principally in the ligation of the umbilical cords of rat fœtuses by passing a needle and thread around the umbilical cord through the intact uterine wall, leaving the conceptus and myometrium otherwise virtually undisturbed. This procedure proved not only highly successful for the intended purpose, but also appeared to offer interesting additional applications in maternal–fœtal interrelations and in studies on the placental barrier. This article deals with a description of the technique and its application for the purpose for which it was originally developed.

Virgin albino rats of the Sprague–Dawley strain, 3–4 months old, raised in our own laboratory on standard food, were used. The date of impregnation was established by limiting contact with male rats to a 24-h period. Females afterwards found not to have been impregnated by this contact served as non-pregnant controls.

As in earlier investigations[1], surgical intervention was carried out on the 19th day of gestation. Under ether anæsthesia, a midline abdominal incision 2 in. long was made and one uterine horn at a time was gently 'delivered' through the abdominal opening, starting at the vaginal insertion and proceeding towards the tip of the horn. The pregnant horn was placed on saline-soaked gauze, and covered with a second moist packing except for the bead to be operated on. The sequence of ligations was begun at the cephalic end of the horn.

In the majority of uterine beads, a loop of the umbilical cord was clearly visible through the thinned-out myometrium. In some a portion of the cord could be readily brought into view by gentle manipulation of the fœtus. As one proceeds caudad, the operation tends to become increasingly difficult because of the decreased manœuvrability of the horn near its vaginal fixation and because of the reduced transparency of the thicker uterine wall. Under these conditions a good binocular loupe and trans-illumination have proved of great help in localizing the umbilical cord.

Under careful visual control, a number 720–20 (Torrington) half circle gut needle, threaded with number 4–0 silk, was passed through the uterine wall around the umbilical cord and out again. The tip of the needle was guided so as to emerge near the point of entry into the myometrium. Care was taken to avoid puncture injury of the fœtus, the placenta, or large uterine vessels. The two ends of the ligature were then grasped and gently tied, thus occluding the umbilical cord and fastening it to the uterine wall. Puncture of the amniotic sac causes some oozing of fluid and jelly-like material which ceases, however, immediately after the knot has been completed. The free ends of the ligature were clipped close to the knot and the procedure repeated with the next fœtus until all cords had been tied in the same fashion. Knotting of the ligature is followed almost immediately by a distinct twitch of the fœtus which may serve as a sign of successful ligation. There are no further movements or convulsions of the fœtus following ligation of the cord.

With some experience a skilled operator can complete the ligature of an umbilical cord in less than 1 min. After completion of all ligations the uterine horns were gently eased back into the body cavity, the abdominal incision was closed, and the animals were permitted to continue to full term (22nd day).

Surgical extirpation of live fœtuses on the 19th day of gestation was effected through individual entry into all uterine beads as outlined previously[1]. Care was taken to minimize disturbing the placentas during this manœuvre. Each uterine incision was closed with a purse-string silk suture.

For the production of the acute hyperparathyroid state, the subcutaneous injection of 'Parathyroid' (supplied by Eli Lilly and Co., Indianapolis, Indiana, through the courtesy of Dr. Glenn W. Irwin) was started immediately following completion of the operation and continued in a dose of 150 units twice daily for three days, as done previously[1]. All rats were killed by decapitation in ether anæsthesia, 72 h after the start of parathyroid hormone injections.

Every animal was subjected to complete post-mortem examination. In pregnant rats, the placentas and fœtuses were removed individually, weighed on a microbalance and then carefully inspected. Histological sections of heart, stomach, kidneys and representative groups of placentas and fœtuses were examined in hæmatoxylin-eosin and von Kossa calcium stains. Samples of these same tissues were, in addition, homogenized for extraction and determination of calcium, magnesium, inorganic phosphate, sodium and potassium. These electrolytes were also determined in terminal samples of maternal serum.

It was found that fœtal exclusion by trans-uterine ligation of the umbilical cord on the 19th day of gestation was remarkably well tolerated by the pregnant rat since it induced no extended disability or signs of discomfort in the remaining days of pregnancy. Near term, the animals were indistinguishable from gravid controls in alertness, activity and food consumption. Distinct retardation of gain in maternal body-weight compared with pregnant controls was ascribed to death of the fœtus.

At autopsy the uteri of rats with tied umbilical cords exhibited the shape, colour and configuration expected of a normal organ near term, except that the individual uterine beads were smaller in size. Each bead contained a dead, slightly macerated fœtus which was smaller than a live fœtus at the time of ligation. The placentas were normal in size and configuration, though slightly lower than normal in weight. They seemed to have suffered little ill-effect from the ligation procedure. This was in marked contrast to our observations with surgical extirpation of the fœtus. There was in particular no evidence of infection, premature placental ablation, or uterine hæmorrhage.

As can be seen from Table 1, trans-uterine ligation of the umbilical cord had no noticeable influence on protection provided by advanced pregnancy against cardiorenal necrosis and calcification as a result of poisoning with parathyroid hormone (group 4). In fact, protection had remained as good as in control pregnant rats (group 2). This finding is in distinct contrast to surgical extirpation of fœtuses, which resulted in conspicuous loss of protection against cardiorenal injury (group 3). These findings militate against the participation of fœtal factors in the antagonism to parathyroid hormone poisoning. They also eliminate any possible role of the fœtus as a reservoir into which a deleterious calcium/phosphate overload of maternal tissues can be readily drained off. The decrease in parathyroid hormone antagonism following fœtal extirpation is thus believed more likely due to interference with maternal protective mechanisms by disturbance of the integrity of the placenta and the uterus. The histological evaluation of tissues and the electrolyte pattern of fœtuses and placentas of the various experimental groups will be reported elsewhere.

The advantages of the method of trans-uterine ligation of the umbilical cord are obvious. The procedure is simple and can thus be readily carried out by anyone who possesses the routine skills of the experimental surgeon. Fœtal exclusion is accomplished without fœtal extirpation and thus with a minimum of disturbance of the pregnant uterus. Preservation of the fœtus maintains the distension stimulus which is believed to be of importance in the continuation of hormonal homeostasis of pregnancy. Finally, the maternal part of the placenta remains apparently anatomically and functionally intact and there is thus no reason for premature ablation.

Table 1. COMPARISON OF UMBILICAL CORD LIGATION WITH FŒTAL EXTIRPATION ON PROTECTION BY LATE PREGNANCY AGAINST CARDIORENAL INJURY OF ACUTE HYPERPARATHYROIDISM

Group No.	Type of rat	No. of rats	Incidence of Myocardial necrosis	Incidence of Nephrocalcinosis
1	*Non-pregnant* Control	30	100%	100%
2	*Pregnant* Intact	20	0	60%
3	*Pregnant* All fœtuses extirpated on 19th day	10	30%	100%
4	*Pregnant* All umbilical cords ligated on 19th day	10	0	70%

All groups received parathyroid hormone, 150 units twice daily subcutaneously for 3 successive days. In pregnant rats, injections were started on 19th day of gestation.

The method lends itself to a variety of additional applications. A few examples may suffice to illustrate this aspect. It is possible, for example, in the acute experiment to 'thread' any desired number of umbilical cords in the described manner without tying the ligatures immediately. Such preparation can serve for transfer investigations across the placental membrane with timed ligations of the threaded umbilical cords at predetermined intervals following intravenous injection of the agents under examination into the maternal circulation. By this arrangement an equilibration curve of the agent between fœtal and maternal blood and tissues could be obtained by elective surgical extirpation of fœtuses immediately following ligation of their umbilical cords for blood and tissue analysis. It is also feasible by this procedure to examine the effects of timed short interruptions of the blood supply on the development of the fœtus when compared with undisturbed control fœtuses of the same mother. This can be accomplished by gentle transient compression of the threaded umbilical cord and subsequent removal of the thread, permitting pregnancy to continue to full term and delivery of live or dead fœtuses, depending on the duration of compression[2].

By ligating umbilical cords at different stages of advanced gestation, one can examine the influence of fœtal death on the physiology of the pregnant state. Moreover, by chemical and histological analyses of fœtuses the exact time of death of which can be predetermined and are carried by the pregnant rat to term, or for a shorter pre-selected span of time, one can obtain information on speed and sequence of resorptive processes and perhaps also on mechanisms of resorption.

Recently, we succeeded in decapitating 19th day fœtuses by a similar trans-uterine approach with good survival of the fœtal bodies until birth[2]. Details of the procedure and of experimental findings will be reported elsewhere.

Application of the method of trans-uterine ligation of the umbilical cord for our particular purpose made it possible to establish that factors of the live fœtus are not essential for antagonism against parathyroid hormone poisoning in advanced pregnancy.

CARBON DIOXIDE EFFLUX FROM THE HUMAN CORNEA *in vivo*

By Prof. IRVING FATT, Dr. RICHARD M. HILL and Dr. GORDON H. TAKAHASHI

College of Engineering and School of Optometry, University of California, Berkeley

THE average carbon dioxide tension in human body tissue is about 60 mm mercury[1]. This is also the gradient between the skin and the ambient atmosphere because air normally has a carbon dioxide tension of only 0·3 mm mercury. Under these conditions an efflux of carbon dioxide from the skin is predicted. The converse uptake of oxygen from the air by the skin, because the average oxygen tension in the body is about 80 mm mercury below that in air, has been observed by Hill and Fatt[2].

Carbon dioxide discharge by the skin cannot be an important part of the total-body discharge because the skin has a much lower area than the lung and is much less vascular. Discharge from the cornea, however, may be important in the normal function of the eye because the cornea is a highly specialized tissue. The human cornea is a thin tissue, 0·53 mm thick and 1·3 cm^2 in area, stretched over a chamber containing an aqueous solution of salts and protein and with a carbon dioxide tension of about 60 mm mercury[3]. Under conditions encountered in diving, flight, or more commonly, when wearing contact lenses, interference with normal carbon dioxide discharge from the cornea may cause physiological disturbances in the eye. The carbon dioxide efflux rate from the human cornea measured *in vivo* is reported here.

Redslob and Tremblay[4] measured the carbon dioxide discharge from the entire eye of the rabbit by passing carbon dioxide-free air over the eye and analysing the effluent gas mixture. They obtained a discharge of 24 µl./h for the whole rabbit eye, averaged from eight experiments, and 53 µl./h for the human eye from one experiment. Their procedure is not easily adaptable for measurements on the cornea alone, particularly on human subjects. Smelzer[5] measured the *p*H of a bicarbonate buffer withdrawn from under a contact lens on a human subject. This measurement can in theory give carbon dioxide efflux from the cornea, but in Smelzer's experiment too many uncertainties, particularly the volume under the lens, prevent a useful calculation from his data.

We have used two methods to measure carbon dioxide efflux from the cornea. In the first method the equipment shown in Fig. 1 (top) was used. The contact lens assembly has been described previously[6]. The electrode assembly was a Beckman model 40279 glass electrode and a silver wire (1 mm diam.) both cemented with epoxy resin into a 'Lucite' rod ($\frac{3}{8}$ in. diam.). The O-ring provided a liquid seal so that the electrode assembly could be pushed into place after the lens was on the subject's eye. The projecting tip of the silver wire, about 1 mm long, was coated with silver chloride by electrolysing for a few minutes at 3 V in a 1-molar sodium chloride solution. The inlet and outlet ducts on the lens assembly allowed new solution to be added while the lens was on the eye. Temperature in the lens reservoir was recorded continuously from the thermistor.

The *p*H of the reservoir solution was observed on a Beckman model 160 physiological gas analyser and recorded continuously, together with the temperature, on Sanborn dual channel model 297 recorder. The Beckman analyser has a *p*H range of only 6·8–8·0. To make readings outside this range a potentiometer, across a 1·34-V mercury cell, was placed in series with the silver chloride electrode lead. This potentiometer circuit provided a variable bucking voltage to bring the observed readings on scale. By this procedure only changes in *p*H were recorded. The absolute *p*H in the lens reservoir at the beginning of an experiment was measured by another, wide-range *p*H meter.

Solutions to be run into the lens reservoir were kept at 35° C in a thermally insulated bottle and run into the lens at the beginning of each measurement. The long, flexible line from bottle to lens, necessary to give the subject freedom of motion when inserting the lens, did allow the solution to cool somewhat, down to 30° C in some cases. This was not a serious problem because temperature in the lens reservoir was always known. All *p*H measurements were corrected to a base temperature, taken to be the steady-state temperature in the reservoir (Fig. 2) through use of the nomograph supplied with the glass electrode by the manufacturer. The reservoir volume of the lens in place in the subject's eye was 0·50 ml. for the assembly in Fig. 1 (top).

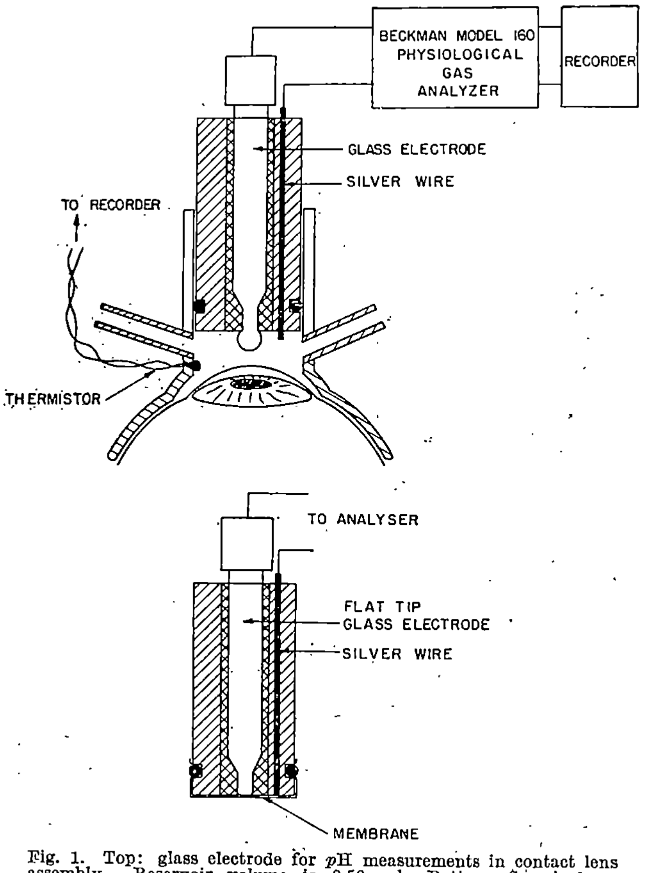

Fig. 1. Top: glass electrode for *p*H measurements in contact lens assembly. Reservoir volume is 0·50 ml. Bottom, Severinghaus carbon dioxide electrode; reservoir volume with this electrode in contact lens assembly is 0·33 ml.

Pergamon Press Publications

Phytochemistry

An International Journal of Plant Biochemistry

Executive Editor: **T.Swain,** Low Temperature Research Station, Cambridge

Covers the area of pure and applied plant biochemistry. It provides a forum for the publication of papers from all parts of the world on every aspect of the subject, especially those which have as their basis a deeper understanding of the factors underlying the development and differentiation of plants and the chemistry of plant products. This quarterly journal is of especial interest to plant biologists, horticulturists, agricultural chemists and those biochemists working in the field of plant products.

Contributions are invited for publication in this journal.

For information on length and style of manuscripts please write to the most convenient address given below.

A free specimen copy of the journal, together with details of subscription rates, will be sent on request.

Supersonic Flow, Chemical Processes and Radiative Transfer

Edited by **D.B.Olfe,** New York University, and **V.Zakkay,** R.I.B.A.L., New York

Partial Contents:

Mixing problems with chemical reactions – V.Zakkay and E.Krause; An investigation of real gas effects relevant to the performance of a kerosine fuelled hypersonic ramjet – R.Hawkins and M.D.Fox; Transonic aspects of hypervelocity rocket plumes – J.Bowyer, L.d'Attorre and H.Yoshihara; Similarity parameters for radiative energy transfer in isothermal and non-isothermal gas mixtures – S.S.Penner, M.Thomas and G.Adomeit; The influence of radiant-energy transfer on one-dimensional shock wave propagation – D.B.Olfe; Radiation heat transfer during re-entry – B.Kivel; Comments on applicability of the Rosseland approximation to shock-heated air – S.S.Penner.

The Faraday Press announces 21 major Soviet Scientific Journals now available for the first time

- **AUTHORITATIVE COVER-TO-COVER ENGLISH TRANSLATION**
- **REGULAR YEARLY SUBSCRIPTION - BEGINNING WITH JAN. 1965 ISSUES**

Nuclear Physics / *Yadernaya Fizika*
Soviet progress at the Kurchatov Institute, at Dubna and other key centers, previously reported in various journals, will now be covered by this indispensable Academy of Sciences publication. *Monthly, $155 / year*

Differential Equations / *Differentsial'nyye Uravneniya*
Offers for the first time in a single journal the original work of outstanding Soviet mathematicians in this increasingly important field. *Monthly, $155 / year*

Theoretical and Experimental Chemistry / *Teoreticheskaya i Eksperimental'naya Khimiya*
Reports on the most important current research of the leading centers throughout the Soviet Union; the equivalent in importance in chemistry to the Soviet J. Theoretical & Exp. Phys. in physics. *Bimonthly, $125 / year*

Soviet Radiophysics / *Izvestiya VUZ. Radiofizika*
Presents original contributions by Troitskiy and other world-famous Soviet radiophysicists dealing with lunar and solar radio emission, the propagation of electromagnetic waves, and other radiophysical phenomena. *Bimonthly, $130 / year*

Soviet Radio Engineering / *Izvestiya VUZ. Radiotekhnika*
Publishes articles on the latest Soviet advances in information theory, high-frequency radio electronics and electrodynamics, and new radio engineering materials and components. *Bimonthly, $120 / year*

Journal of Applied Mechanics and Technical Physics / *Zhurnal Prikladnoy Mekhaniki i Tekhnicheskoy Fiziki*
A wide-ranging journal of importance to applied physicists, and mechanical, aeronautical, chemical, and structural engineers. *Bimonthly, $155 / year*

Soviet Physics / *Izvestiya VUZ. Fizika*
Covers advanced Soviet theoretical and experimental investigations in plasma physics, optics, molecular physics, electronic processes and the entire range of physics research. *Bimonthly, $130 / year*

Astrophysics / *Astrofizika*
Describes Soviet research in lunar, interplanetary, solar and stellar physics, as performed under the direction of V. A. Ambartsumyan and other leading astrophysicists. *Quarterly, $95 / year*

Polymer Mechanics / *Mekhanika Polimerov*
Keeps the reader informed on the latest and most valuable developments in Soviet polymer research and applications. *Bimonthly, $125 / year*

Heat and Power / *Teploenergetika*
Reports the latest advances in heavy power equipment and automation, fuels and combustion, turbomachinery design, and thermophysical properties. *Monthly, $225 / year*

Applied Solar Energy / *Geliotekhnika*
A significant new journal, devoted entirely to a subject in which Soviet scientists are making outstanding contributions. *Bimonthly, $115 / year*

Journal of Organic Chemistry / *Zhurnal Organicheskoy Khimii*
Of interest to every Western organic chemist, this new journal will be the principal source of information on Soviet research in this field, previously available only as scattered articles in many journals. *Monthly, $165 / year*

Journal of Applied Spectroscopy / *Zhurnal Prikladnoy Spektroskopii*
Describes the many expanded and new applications of spectroscopy in the various engineering and scientific disciplines. *Monthly, $155 / year*

Journal of Engineering Physics / *Inzhenerno-Fizicheskiy Zhurnal*
Devoted to Soviet basic and applied research in heat and mass transfer and exotic heat sources; highly valuable, presenting many original contributions. *Monthly, $155 / year*

Magnetic Properties of Liquid Metals / *Magnitnaya Mekhanika Zhidkikh Metallov*
Increasing research and success in technological applications of magnetism in the Soviet Union have led to the publication of this important new journal. *Quarterly, $95 / year*

Chemistry of Heterocyclic Compounds / *Khimiya Geterotsiklicheskikh Soyedineniy*
Expanding Soviet research in this increasingly important area has contributed this vital new journal. *Bimonthly, $125 / year*

Chemistry of Natural Compounds / *Khimiya Prirodnykh Soyedineniy*
The Soviet journal devoted to original research in the structure, modification and synthesis of natural compounds. *Bimonthly, $115 / year*

Electrical Engineering / *Elektrotekhnika*
Reports the latest, most important advances in Soviet electrical equipment and instrumentation. *Monthly, $165 / year*

Applied Biochemistry and Microbiology / *Prikladnaya Biokhimiya i Mikrobiologiya*
Research in this field is producing extensive and valuable new applications in many areas of industry and medicine; reviewed fully in this critically important new journal. *Bimonthly, $125 / year*

Physicochemical Properties of Materials / *Fiziko-Khimicheskaya Mekhanika Materialov*
Of great importance to industry, this journal reports on new materials being developed in the Soviet Union, their properties and specific applications. *Bimonthly, $120 / year*

Cybernetics / *Kibernetika*
Offers a complete review of current achievements and long-range goals in this field being rapidly developed in the Soviet Union, in which top Soviet talent is being concentrated. *Bimonthly, $120 / year*

Note: Yearly subscriptions and back copies (1962-current) to "Soviet Engineering Physics Abstracts" and "Soviet Heat and Power Abstracts" are still available—write for further information.

Order your 1965 subscriptions to the essential Soviet journals described above from:

CANINE BEHAVIOR:

A History of Domestication; Behavioral Development and Adult Behavior Patterns; Neurophysiology; Psychobiology; Training, Inheritance, Early Experience and Psycho-Social Relationships; Experimental Neuroses and Spontaneous Behavioral Abnormalities; Congenital Anomalies and Differential Diagnosis of Neurologic Disease

By **M. W. Fox,** *Galesburg State Research Hosp., Galesburg, Ill.* Describes experiments in which dogs were used in psychobiological research to throw light on mental health problems in man. *Special attention is focused on the normal rearing and training of the dog.* The diagnosis, treatment, or prophylaxis of spontaneous behavioral abnormalities are discussed in detail.

August 1964 *About* 176 *pp.*
About 23 *figs.*

THE LAWS OF BONE STRUCTURE

By **H. M. Frost,** *Henry Ford Hosp., Detroit, Mich.* This monograph deals with one of the most basic properties of living matter—*the control of directionality of cell activity in three dimensional space.* The laws presented here represent a breakthrough on the theoretical side of biomechanics. A series of appendices provides basic information about the mathematics, materials, properties, and bone physiology involved. Technical terms are defined in the glossary. (*Henry Ford Hospital Surgical Monograph edited by Conrad R. Lam.*)

August 1964 *About* 325 *pp.*
About $7.50 83 *illus.*

PHYSIOLOGICAL PROBLEMS IN SPACE EXPLORATION

Edited by **James D. Hardy,** *Yale Univ., New Haven, Conn.* (*With 7 Contributors*). Presents background information and the state of knowledge in the several aspects of space psychophysiology: Temperature Problems; High Energy Radiations; The Gaseous Requirements (Respiration); Food Requirements; Acceleration; Weightlessness and Sub-Gravity Problems; Sensory and Perceptual Problems; Isolation and Disorientation; and Physiologic Rhythms. (*Amer. Lec. Physiology*)

May 1964 344 *pp.*
$12.50 100 *illus.*

THE ZYMOGRAM IN CLINICAL MEDICINE

By **S. H. Lawrence,** *Univ. of Calif., Los Angeles, Calif.* The author introduces enzymology into medicine and develops advances which have led to the discovery and practical values of the heterogeneity of enzymes. *He discusses its relation to diagnosis and genetics and probes into the future of this new tool.* Also included are the most widely used methods for the study of the zymogram with detailed tables of stains, buffers, substrates, activators, and inhibitors. An important book that will persuade researchers of the diagnostic potentials of the "multizymogram" as opposed to study of isozymes of only one enzyme. (*Amer. Lec. Living Chemistry edited by I. Newton Kugelmass*)

June 1964 124 *pp.*
$5.75. 33 *illus.*

7 IMPORTANT NEW BOOKS IN SCIENCE AND TECHNOLOGY

THE CHEMICAL ORIGIN OF LIFE

By **Alexander I. Oparin,** *U.S.S.R. Academy of Sciences, Moscow, U.S.S.R. Translated from the Russian by* Ann Synge, *Stonehaven, Scotland.* In this classic monograph Doctor Oparin describes in as great detail as achievements of contemporary science will allow the three stages in the evolution of organic substances which preceded the appearance of life on Earth. He makes the widest possible use of the data of evolutionary biochemistry to sketch in a picture of later development of biological metabolism and cellular structure. (*Amer. Lec. Living Chemistry*)

July 1964 *About* 80 *pp.*
About $4.75 33 *illus.*

STEROID ANALYSIS BY GAS LIQUID CHROMATOGRAPHY

By **A. Anne Patti** and **Arthur A. Stein,** *both of Albany Medical Coll., Albany, N.Y.* Presents observations utilizing gas-liquid chromatography (GLC) for steroid analysis in biological fluids and tissues. Selected methods which give reproducible results with semi-purified extracts and which permit the separation and identification of one or more steroids in biological fluids are described. *These methods have been chosen for rapid clinical screening.* Some biochemistry is included to clarify the methodology and *applications of GLC to steroid analysis in the normal and diseased states.*

July 1964 *About* 124 *pp.*
About $6.25 17 *illus.*

COPPER AND PEROXIDES IN RADIOBIOLOGY AND MEDICINE

By **Jack Schubert,** *Nuclear Science and Engineering Corp., Pittsburgh, Pa.* An unusual book . . . written not to satisfy but to *stimulate research on the unique and widespread role played by copper in living organisms.* Includes chapters critically reviewing selected aspects of current knowledge of copper chemistry; copper in biochemistry and medicine; peroxides and copper oxidases in radiobiology. Medical aspects include new views on Wilson's disease, cancer and aging, antipyresis, and hypothermia. *Special emphasis is given to radiobiology.*

August 1964 *About* 208 *pp.*
About $8.75 18 *illus.*

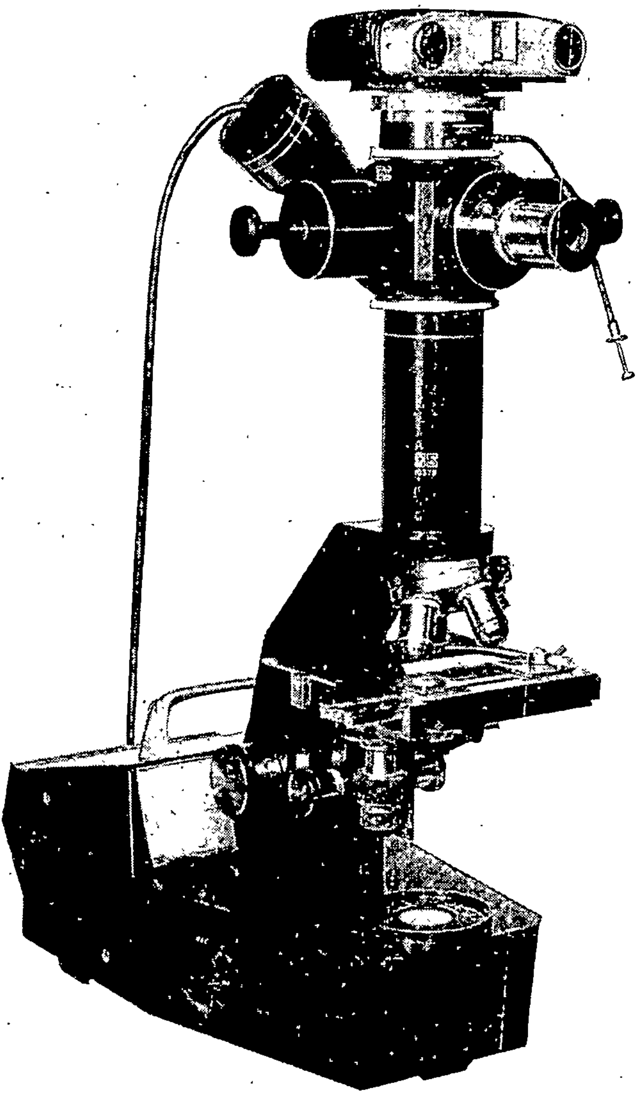
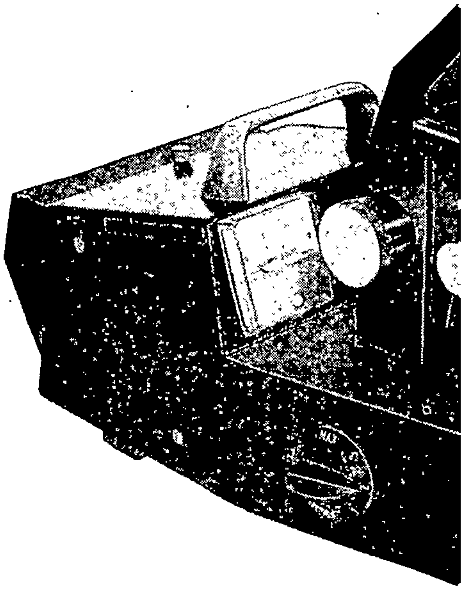
BLUE-LIGHT/ULTRA



VERTICAL PHOTO CONFERENCE

Conference microscope for brightfield, darkground, phase contrast and fluorescence, with photo-micrographic attachments, for less than £500.



BINOCULAR CONFERENCE

Routine fluorescence microscope with b

The Conference microscope is now avail
cence—yet another addition to the remar
the world's most remarkable microscope

THE CONFERENCE MICROSCOP

OLET FLUORESCENCE

Q Which routine fluorescence microscope with binocular costs less than £300?

A The Gillett & Sibert Conference.

Q Which microscope offers you the facilities of brightfield, darkground, phase contrast (positive or negative) *and* fluorescence for less than £500—with photo-micrographic attachments and coupled ultra sensitive light meter included within that price?

A The Gillett & Sibert Conference.

Q Which microscope allows you to make colour photographic exposures of your fluorescent specimens in two—three minutes without bleaching?

A The Gillett & Sibert Conference.

Q Is there a microscope available which is one neat, compact and portable unit, with built-in light source *and* built-in transformer?

A Yes—the Gillett & Sibert Conference.

Q What do you need to adapt a standard research-type Conference microscope for fluorescence?

A A set of filters.

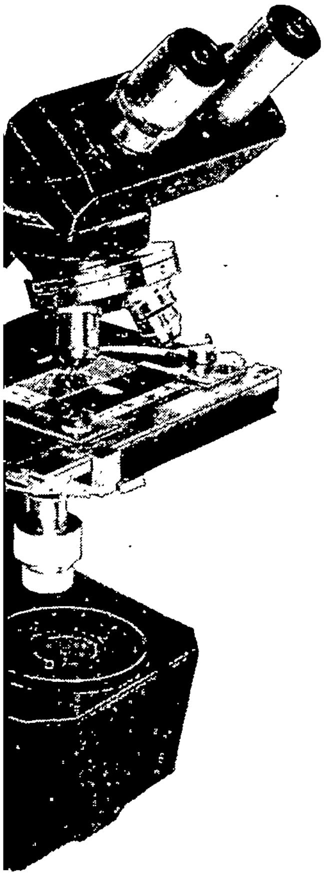
Q Which is the safest and simplest microscope to set up and use for fluorescence observations and photo-micrography?

A The Gillett & Sibert Conference.

Q Are you yet convinced?

A No—of course you're not, for only seeing is believing.

Q May we have the chance to show you this equipment, and convince you of what we say?



r for less than £300.

ı the added facility of fluores-
nge of possibilities with this,

GILLETT & SIBERT

Why not contact us for further information, and at the same time, tell us which fluorochromes you are using?

MICROMANIPULATORS

if you use a

MICROSCOPE

you need a

SINGER

FULLY PATENTED

MICROMANIPULATOR

Singer micromanipulators are used in most laboratories all over the world. Three types available:

Mk I Low power for magnifications ×1 to ×200

Mk II For magnifications ×1 to ×500

Mk III High power for magnifications ×100 to ×1,000 *plus*

The most advanced instruments for micromanipulation. As described by Barer and Saunders-Singer with further improvements.

Full details and demonstrations upon request to :

SINGER INSTRUMENT CO. LTD.,
Fountain Court, 83 London St.,
Reading, Berkshire, England.
Telephone: Reading 53613.

Synthetic Polyribonucleotides

Prepared by polymerization of nucleotides with polynucleotide phosphorylase from *Micrococcus lysodeikticus*,

These polynucleotides are of high molecular weight, suitable for both physical-chemical and biochemical studies.

In stock for immediate shipment are salts of :

Polyadenylic acid
Polyinosinic acid
Polyuridylic acid
Polycytidylic acid

Copolymers are custom synthesized with 2 to 4 different bases in any given ratio of substrates.

Custom synthesis of C^{14} and H^3 labelled homopolymers and copolymers can also be accomplished.

For information and prices write to :

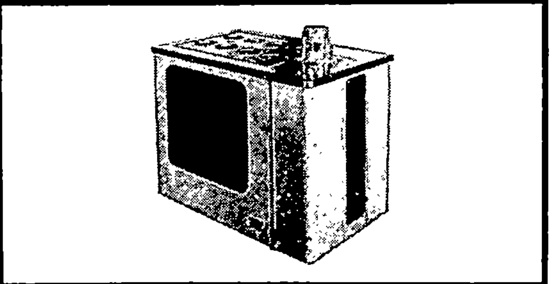
Thermostatic Bath Type C. T. 3



A New Temperature Control System with no moving parts.
An accuracy better than 0.01 C. at 100°C.

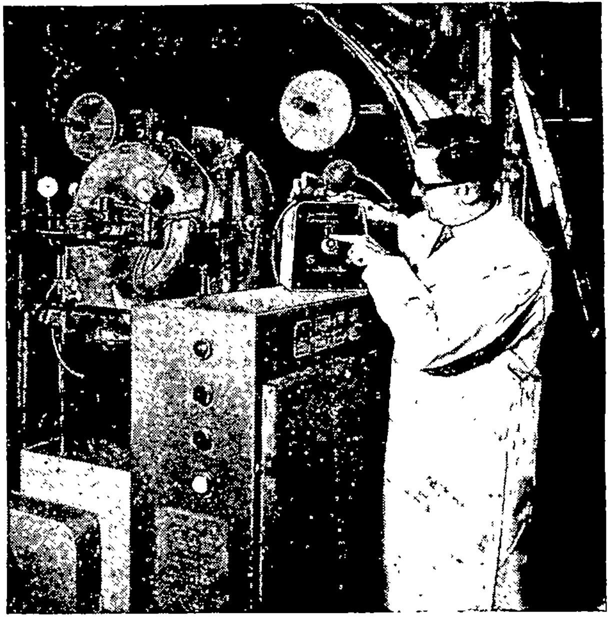
The replacement of any part of the control gear, heater or stirrer without draining the bath.

Operating ranges either 20°C. to 90°C.; or 80°C. to 150°C.

Large area double glazing on each side affords maximum vision for viscometry at any temperature up to 150°C.

Illustrated catalogue on request to
Laboratory Thermal Equipment Ltd.
Greenfield, Nr. Oldham.
Telephone: Saddleworth 3221 2

Still using Orsat apparatus? It's quicker with the Servomex DCL101 Oxygen Analyser



This new oxygen analyser is an essential instrument for accurate determination of the oxygen content of boiler flue gases.
It competes with chemical absorption methods for accuracy, but is also quick—sampling can be made in 30 seconds—clean, reliable and extremely simple to use. Completely portable, it is ready for use anywhere and it is not easily damaged by rough handling.
The analyser will measure oxygen content to 0.1% and boiler controls can be set precisely without having to make allowance for the burner modulating.

The photograph shows the analyser being used by the Technical Services Department of Esso Petroleum Company Ltd. Send for Data Sheet.

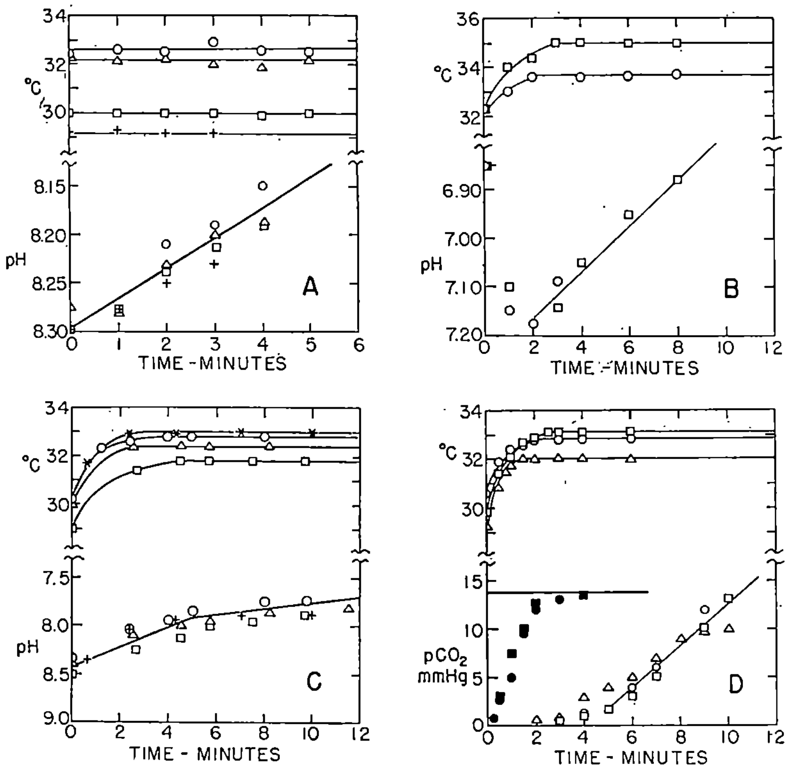

Fig. 2. pH and carbon dioxide tension as a function of time for various solutions in lens reservoir: A, pH in 0·0336 molar bicarbonate; B, pH in isotonic saline (no bicarbonate); C, pH in 0·01 molar bicarbonate. All bicarbonate solutions have sodium chloride added to make solution physiologically isotonic in total ions. D, shows increase in carbon dioxide tension in isotonic sodium chloride using carbon dioxide electrode of Fig. 1 (bottom). Upper curves are temperature record during measurements. Solid data points in D show electrode response to step increase in carbon dioxide tension

The response time of the pH electrode assembly in Fig. 1 (top) was less than one second, as observed by quickly moving the electrode from a pH 8·5 buffer to one at pH 7·0.

The reaction occurring when carbon dioxide from the cornea enters the solution in the lens reservoir is $CO_2 + H_2O = H^+ + HCO_3^-$. The mass action equilibrium equation for this reaction can be differentiated with respect to time to give:

$$\frac{d([CO_2] + [HCO_3^-])}{dt} = (K[H^+] + 1)\,\frac{d([HCO_3^-]_1 + [HCO_3^-]_2)}{dt} - 2{\cdot}3K[H^+]\,[HCO_3^-]\,\frac{dpH}{dt} \quad (1)$$

where the left-hand side is the total change in carbonate content in the lens reservoir and K is the association constant for bicarbonate and hydrogen ion ($0{\cdot}21 \times 10^7$ l./mole at the usual temperature in the lens). Subscript 1 refers to bicarbonate introduced by reaction of carbon dioxide and water, subscript 2 refers to bicarbonate ion coming directly from the cornea by diffusion. No subscript on a bracket indicates total bicarbonate.

When the solution put into the lens reservoir has the same ionic composition as the aqueous humour, 0·0336 molar in bicarbonate ion and 0·10 molar in chloride ion, then there is no flux of bicarbonate ion, $\frac{d[HCO_3^-]_2}{dt}$ is zero, and equation (1) reduces to:

$$\frac{d([CO_2] + [HCO_3^-])}{dt} = -\,2{\cdot}3[H^+]\,\frac{dpH}{dt}\,\{K[H^+] + K[HCO_3^-] + 1\} \quad (2)$$

Numerical values of the terms on the right-hand side of equation (2) are available from Fig. 2A. These data are for four runs on a human subject using an air-equilibrated solution of ion composition already mentioned in the lens reservoir. These data give a carbon dioxide efflux from the cornea of 21 μl./h. The diffusion coefficient for carbon dioxide in the cornea can now be calculated assuming the interior of the eye at 60 mm mercury carbon dioxide tension and the exterior at 0·3 mm mercury. The dimensions of the cornea are taken as given above. The diffusion coefficient is then $0{\cdot}50 \times 10^{-5}$ cm^2/sec.

In a second set of measurements using the pH electrode of Fig. 1 (top) the solution in the lens reservoir was 0·01 molar in bicarbonate ion, 0·10 molar in chloride ion, and air-equilibrated. Under these conditions there is a flux of both carbon dioxide and bicarbonate ion. The bicarbonate ion change in the lens reservoir is then given by equation (3):

$$\frac{d[HCO_3^-]}{dt} = \frac{1}{K[H^+]}\,\frac{d[CO_2]}{dt} + 2{\cdot}3\,[HCO_3^-]\,\frac{dpH}{dt} \quad (3)$$

At zero time we can take the bicarbonate ion concentration as 0·01 molar and the carbon dioxide flux as that determined from the previous experiment. The slope of the data in Fig. 2C at zero time gives $\frac{dpH}{dt}$. The bicarbonate ion flux across the cornea is then calculated from equation (3) and found to be $0{\cdot}75 \times 10^{-2}$ mM/h. From the cornea dimensions given above and the imposed bicarbonate ion concentration gradient, the diffusion coefficient for bicarbonate ion in the cornea is calculated from this flux to be $0{\cdot}38 \times 10^{-5}$ cm^2/sec.

From the diffusion coefficients for carbon dioxide and bicarbonate ion in the cornea we can calculate the accumulation of bicarbonate in the lens reservoir when it is filled with 0·01 molar bicarbonate solution at zero time. At the end of 8 min the bicarbonate concentration rises to 0·0118 molar. When this bicarbonate concentration and the observed pH at 8 min is used in equation (3) together with a bicarbonate flux calculated for this concentration, the predicted slope in Fig. 2C is 0·028 pH/min. A line of this slope is drawn through the experimental data at 8 min and is a good fit.

In a second procedure to measure carbon dioxide efflux from the cornea an isotonic saline solution was placed in the lens reservoir and carbon dioxide tension increase in this solution was measured directly. pH measurements were also made separately for isotonic saline solution (Fig. 2B).

The carbon dioxide tension was measured with a Severinghaus type electrode[7] (Fig. 1). The glass electrode, provided on special order by Beckman, Inc., Fullerton, California, had the same dimensions as their model 40279, but had a flat tip. This glass electrode and a silver wire were cemented into a 'Lucite' rod as was done with the round tip electrode except that a flat surface was obtained. A drop of solution containing 0·1 molar potassium chloride with 0·01 molar sodium bicarbonate solution was placed on this surface and then covered by a 12μ thick sheet of polyethylene held in place by the O-ring. Air bubbles were carefully squeezed out before installing to O-ring.

The carbon dioxide electrode was connected to the pCO_2 input of the Beckman analyser. The analyser was adjusted to read pCO_2 directly by placing the electrode first into air-saturated water ($pCO_2 = 0{\cdot}3$ mm mercury) and then into water equilibrated with a carbon dioxide–nitrogen mixture ($pCO_2 = 13{\cdot}7$ mm mercury). The output of the analyser is then directly, on a logarithmic scale, the carbon dioxide tension of any solution into which the electrode is placed.

The response of the carbon dioxide electrode when moved quickly from a solution at 0·3 mm mercury carbon dioxide tension to one at 13·7 mm mercury is shown for two tests by the solid data points in Fig. 2*D*. This relatively slow response requires that the observed build-up of carbon dioxide tension, when the electrode is in the subject's eye, be corrected to give the true build-up rate. This correction is made by the numerical evaluation of the convolution integral as is conventional in instrument control theory.

The change in carbon dioxide tension in the lens is given by;

$$\frac{d[CO_2]}{dt} = K[H^+]\,\frac{d([HCO_3^-]_1 + [HCO_3^-]_2)}{dt} - 2{\cdot}3[CO_2]\,\frac{dpH}{dt} \qquad (4)$$

The first term on the right-hand side of equation (4) can be calculated from data previously obtained and the second term from Figs. 2*B* and *D*. Equation (4) predicts a carbon dioxide tension change of 2·55 mm mercury/min at 8 min. The slope of the uncorrected data in Fig. 2*D* is 2·0 mm mercury/min at 8 min, and corrected for finite response time of the carbon dioxide electrode is 3·0 mm mercury/min. From this result we conclude that the data collected by *p*H measurements in bicarbonate solutions, as used in equation (4), are valid.

Figs. 2*B* and *D* require further comment. The very slow rise in carbon dioxide tension during the first 4 min in Fig. 2*D* is attributed to the reaction of carbon dioxide with water to give mostly bicarbonate ion during this time-interval. After 4 min the *p*H falls, as shown in Fig. 2*B*, so that carbon dioxide entering from the cornea tends to remain as dissolved gas.

In Fig. 2*B* the increase in *p*H during the first minute is attributed to the combined effect of efflux of bicarbonate ion from the cornea and the formation of bicarbonate ion from the carbon dioxide.

All the calculations made here are based on the assumption of steady-state diffusion. The validity of this assumption can be easily demonstrated by noting that, for the cornea dimensions and diffusion coefficients, Fatt[8] has shown steady state is reached in 3 min. For each run shown in Fig. 2 the cornea was bathed in the test solution for at least this length of time before measurements were made.

The assumption of constant composition in the anterior chamber is not easily verified. The highly vascular nature of the ciliary body probably maintains constant composition in spite of the efflux across the cornea.

This work was supported in part by U.S. Public Health Service grant *HE* 06796 to one of us (I. F.) from the National Institutes of Health, U.S. Public Health Service.

SURVIVAL OF EHRLICH'S ASCITES CARCINOMA CELLS AT HIGH ULTRA-CENTRIFUGAL FORCES

By DR. NORMAN MOLOMUT, DR. MORTON PADNOS, VIOLET SATORY and LEO GROSS

Waldemar Medical Research Foundation Inc., Woodbury, New York

WE have found that ultracentrifugation will not sediment all cells in a suspension but that a small number of tumour or bacterial cells will remain in the supernatant even after prolonged centrifugation. This was discovered while attempting to confirm the work of Tolnai *et al.*[1], who reported Ehrlich ascites tumour induction from cell-free supernatants of the ascitic fluid obtained by centrifugation up to 105,000*g* for 1 h.

We repeated Tolnai's experiment with Ehrlich ascites carcinoma, adding ultracentrifugation of the ascitic fluid for 105,000*g* for intervals up to 5 h. We similarly obtained Ehrlich ascites tumour induction from the supernatant fractions.

Injection of such supernatant fractions in mice into several different anatomical sites, including intracerebral, resulted in a rapid induction of tumour morphologically typical of Ehrlich carcinoma cells. The identity of these induced tumours was confirmed by quantitative immunological means described previously[2].

Additional data on the physical properties of the reported[1] inducing agent appeared to be more consistent with the presence of whole cells rather than subcellular particles. We therefore repeated the differential centrifugation, instituting rigid tests to ascertain whether the resulting supernatants of 105,000*g* for 1 or more hours were indeed free of cells.

Ehrlich ascites carcinoma, originally obtained from Dr. Sugiura in November 1960, is carried routinely in C_3H mice in our laboratory and was in the 127th passage on April 20, 1964. This carcinoma grows in all mouse strains. Approximately 100 ml. of ascitic fluid was collected from the routine passage of Ehrlich ascites carcinoma in C_3H mice. The pooled ascitic fluid was subjected to differential centrifugation at 5° C. The supernatants were carefully pipetted away and the sedimented pellet from each step was discarded. All supernatants were removed from the centrifuge with a rigidly supported pipette, with care taken to avoid possible re-suspension of the pellet. The steps were 8,000*g* for 10 min, then 12,000*g* for 10 min both in a Lourdes model *L* refrigerated centrifuge, followed by 105,000*g* for 1 h, then at 105,000*g* for an additional 4 h both in a Spinco model *L* ultracentrifuge.

The supernatants of the 105,000*g* 1-h and 5-h centrifugations were divided into two portions. One was filtered through a 02 Selas filter, the pore size of which is 1·7μ;

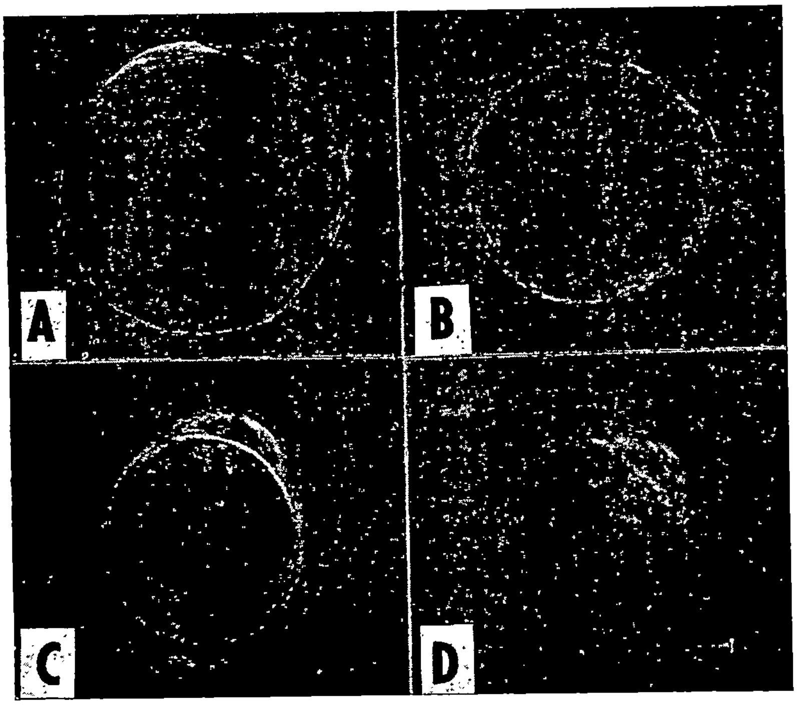

Fig. 1. *A* and *B*, individual Ehrlich ascites carcinoma cells observed in a supernatant centrifuged at 105,000*g* for 1 h. Note that the nuclei are causing distension of the cell membrane. *C* and *D*, cells obtained from a supernatant centrifuged at 105,000*g* for 2 h reveal the progressive evagination of the cell membrane

a second portion was left unfiltered. Both filtered and non-filtered portions were then injected intraperitoneally in 0·25 ml. volumes into different inbred strains of mice.

Both unfiltered 105,000*g* supernatants of the 1-h and 5-h centrifugation induced Ehrlich ascites tumour in 15–25 days in mice of several inbred strains. In repeated trials, supernatants were found to vary in tumour-inducing activity in mice of the same strain, sex, age and weight (Table 1). Filtered supernatants were completely inactive in all mice tested and observed for a period of 90 days.

In addition, we found that active supernatants were inactivated by freezing at – 20° C for short periods followed by thawing prior to testing. These data suggested that the tumour-inducing agent obtained from the unfiltered supernatant might be cellular since cells are killed by freezing and thawing.

A careful search was made for residual tumour cells in the supernatants following 105,000*g* centrifugation. Samples were taken from three different levels of the supernatant in the centrifuge tube, and 0·5 ml. of the unfiltered supernatants distributed in 0·02 ml. drops on thoroughly cleaned microscope slides were examined with phase objectives at times 100 and times 200 magnification without a cover slip. Small numbers of vacuolated cells with intact or deformed nuclei and some with the nuclei in an evaginated protrusion of the cell membrane were observed near the air–liquid interface of the drops. Approximately the same number of cells were seen in the 1-h and 5-h samples, the 5-h exposure causing greater evagination of the portion of the cell membrane in contact with the nucleus (Figs. 1 and 2).

An additional test involving five 1-h serial centrifugations at 105,000*g* was performed. After each 1-h centrifugation only the middle portion of the supernatant was removed and transferred. At the end of the 5th hour we still observed these deformed cells by direct phase microscopy. The concentration of suspended cells remained relatively unchanged at 250–300 cells per ml. (Table 1).

The number of cells required to kill 50 per cent of their hosts (LD_{50}) is approximately 40 Ehrlich ascites carcinoma cells in Swiss mice as indicated in Table 2. Since a comparable number of vacuolated cells produce similar results, they apparently survive after ultracentrifugation. They appear to be as viable and lethal to their hosts on transplantation as vacuole-free cells that were never subjected to centrifugation.

A few vacuolated tumour cells varying in size are normally present in peritoneal aspirates obtained from mice with progressing Ehrlich ascites tumour and can be readily observed in stained smears (Fig. 3). Cell vacuolation is not a special characteristic of the Ehrlich ascites carcinoma, but has been observed consistently in our laboratory for other transplantable ascites tumours, for example, sarcoma I, and *Ca* 755 mammary adenocarcinoma.

We were able to obtain tumour induction from ultracentrifugates of the *Ca* 755 ascites adenocarcinoma and have observed similarly the presence of deformed vacuolated tumour cells in the unfiltered supernatants.

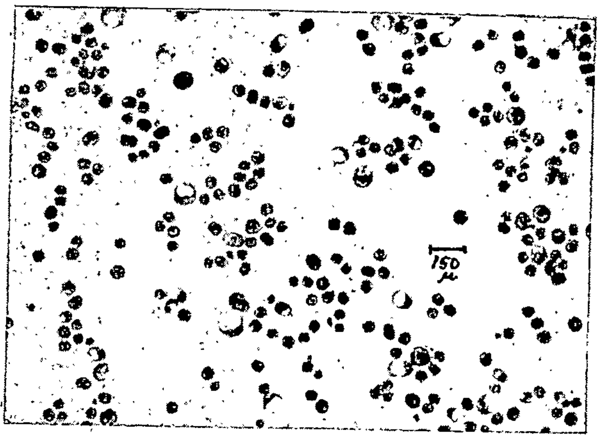

Fig. 3. Hæmatoxylin and eosin stained smear of Ehrlich ascites carcinoma aspirated from C_3H mice at nine days after transplantation showing approximately 10 per cent vacuolated cells

It is apparent that the cells found floating in the ascitic fluid after prolonged ultracentrifugation are of a specific gravity comparable to that of the ascitic fluid. The presence of vacuoles in these cells results in an overall specific gravity smaller than that of the more populous cells which are heavier and sediment.

The possibility that Selas filters may absorb a filterable agent, if present, was controlled by filtration using 290 mμ 'Gradocol' membranes, which absorb minimal protein. The injected filtrate did not induce tumours in 90 days in the most susceptible mouse strain (Swiss mice), confirming results obtained by Tolnai *et al.* with filtered ascitic fluid[3].

In summary, rigidly controlled conditions indicate that centrifugation at 105,000*g* for 5 h in one run or serially for five 1-h runs does not sediment all suspended cells of Ehrlich ascites carcinoma, and other tumours in the ascites form.

It is therefore vital that all claims for subcellular tumour-inducing agents obtained solely by high-speed centrifugation should be carefully reviewed for the definite absence of cells.

Our data indicate that vacuolated viable cells, though deformed by the high centrifugal forces, are found in the supernatant and are capable of survival, transplantation and progressive growth in susceptible mice. Tolnai *et al.*[1,3] have observed these suspended cells, and report that they are confined only to the lipid layer, which they skim off the supernatant. Our work shows that vacuolated cells can be found throughout the supernatant. Another claim of tumour induction from ultracentrifugal supernatants[4] is probably due to suspended vacuolated cells. In virulent tumours for which a low LD_{50} exists, the small number of cells required to induce tumour escape detection in unfiltered ultracentrifugates.

The observed vacuolated cells remain in suspension after centrifugation because of their apparently lowered specific gravity. The nucleus, which is denser than the cytoplasm, is drawn down into contact with the cell membrane and progressive centrifugation increases the distortion and evagination of the membrane. The recuperative powers of the Ehrlich cells so treated must be quite high, since they exhibit approximately the same virulence (LD_{50}) as cells not centrifuged.

We thank Dr. J. S. Murphy, of the Rockefeller Institute of New York, for his advice. This work was supported in part by the U.S. National Institutes of Health, grant *CA* 07114, and Mr. Wilfred P. Cohen of Great Neck, New York.

VARIATION OF THE RELATIVE SENSITIVITY OF CLOSELY RELATED NEOPLASTIC CELL LINES IRRADIATED IN CULTURE IN THE PRESENCE OR ABSENCE OF OXYGEN

By LÁSZLÓ RÉVÉSZ and BO LITTBRAND

Department of Tumour Biology, Karolinska Institutet Medical School, Stockholm

THE examination of the differential effect of various treatments in modifying the relative radiosensitivity of closely related cell lines which have genetically or biochemically well-defined differences proved to be a fruitful experimental approach to obtain information about the mode of action of radiation[1]. In accordance with this approach, and in an extension of previous investigations[2,3], a series of experiments was performed in which cultures of an Ehrlich ascites tumour and its selected sublines were used as the cellular material, and sensitization by oxygen was used as the modifying treatment. This article reports the results of these experiments and some of the conclusions which can be drawn from them.

The Ehrlich tumour of this work was a hyperdiploid cell line, denoted *ELD*. One of the sublines, *ELT*, represents the cloned derivative of a predominantly hypertetraploid population, isolated from *ELD*. Another subline, clone *g*, has been derived from a serially irradiated line of *ELD*, denoted *SELD*. The details of the isolation of the clones and several characteristics of the cell lines, including certain growth characteristics, chromosomal variation, radiosensitivity, DNA and sulphydryl content, have been examined and are described in previous publications[4].

In vitro cultures of these lines were established from ascitic material. Freshly withdrawn ascites of the respective tumour line were dispensed in 0·1 ml. amounts in several stoppered 'Pyrex' tissue-culture vessels. The medium contained Eagle's solution[5], pregassed with carbon dioxide and supplemented with 15 per cent fœtal calf serum and antibiotics. After a period varying between 7 and 18 days, multiple foci of vigorously growing colonies became visible which were firmly attached to the bottom of the culture flasks. The colonies were detached and dispersed by gentle trypsin treatment and, afterwards, the cells were cultivated in serial passage by transfers of 10^4 cells at weekly intervals, and by medium changes on each second or third day. The plating efficiency, expressed as the percentage of cells which grew into macroscopic colonies in about 10 days, varied between 25 and 100 per cent (cf. cols. 5 and 6, Table 1). In order to protect against major alterations, prone to occur in cell strains

Table 1. THE SLOPE CONSTANT AND EXTRAPOLATION NUMBER OF SURVIVAL REGRESSIONS AND THE MEAN LETHAL DOSE, (D_0), CALCULATED BY LEAST-SQUARE ANALYSIS FROM THE MEAN OF SURVIVING FRACTIONS OF IRRADIATED CULTURES WHICH ARE ILLUSTRATED IN FIG. 1

maintained in prolonged serial cultures *in vitro*, the chromosomal constitution of the cell populations was examined at intervals of about 10 successive passages, as described previously[2,4]. Whenever shifts were noted in the modal chromosome number or the chromosomal markers identified in previous investigations[2], the propagation of the line was discontinued, and new cultures were established from the original ascitic material preserved in the frozen state.

Reproductive integrity of the cells, as judged by their clone-forming ability, was used as the measure of radiosensitivity. Suspensions of single cells were prepared from cultures growing in non-confluent monolayers which readily dissociated on treatment with trypsin. After counting in a hæmocytometer and diluting as necessary, the appropriate number of cells was added to a series of 6-cm Petri dishes, containing 4–6 ml. of nutrient medium. The number of cells explanted (2×10^2–6×10^5) was chosen with respect to the size of the expected surviving fraction after a particular treatment. The dishes were incubated at 38° C in a moist atmosphere of carbon dioxide in air to maintain a *p*H of 7·0–7·2. After incubation for 3 h the cells were irradiated and re-incubated for 10 days, with medium changes taking place at 3–4 day intervals. Afterwards, clones fixed and stained *in situ*, comprising more than fifty cells, were counted and the number of clones was taken to represent the surviving fraction. In each experiment, mean values were calculated of three (irradiated cultures) or six (unirradiated controls) replicate dishes. The standard error was 8 and 5 per cent respectively, as determined from a total of 170 randomly chosen individual observations. The fraction of cells surviving irradiation was calculated as a percentage of unirradiated controls in the same experiment.

Exposure to X-rays was made at room temperature in an air-tight plastic chamber of 3 l. volume. The lids were removed from the culture dishes, and the nutrient medium was withdrawn to such an extent that a layer of only about 1 mm fluid was left to cover the cells. For 20 min prior and during irradiation, the chamber was gassed with either oxygen or argon, both containing 1·25 per cent carbon dioxide, at a flow rate adjusted to 6 l./min. Control cultures were subjected to the same procedure as irradiated ones. The plating efficiency of the controls equilibrated with the oxygen–carbon dioxide mixture did not differ significantly from those gassed with the argon–carbon dioxide mixture (cf. cols. 5 and 6, Table 1). The gases were led through pre-equilibrated water warmed slightly above room temperature. Argon was cleaned in the factory by burning out its oxygen contamination by hydrogen. Its oxygen content was less than 3 p.p.m., as measured according to the method of Tödt[6]. Radiation was generated in a Siemens X-ray unit at 190 kV and 15 m.amp, was filtered by 1 mm aluminium, and had half-value layer of 0·95 mm copper. The dose rate, measured by means of ionization chamber, was 235 r./min at the bottom of the culture dishes at a distance of 43 cm from the focus.

The mean surviving fraction of several *ELT*, *ELD* and *SELD* clone *g* cultures, irradiated with different X-ray doses in either oxygen or argon, is illustrated, together with the 95 per cent confidence limits, in Fig. 1. The regression lines, calculated by the method of least-square analysis from the means of the respective tumour populations, are also shown. The 95 per cent probability limits of survival after different radiation doses are indicated by shading round the line, and were calculated, based on statistical theory[7], according to equation (1):

$$V(\log \hat{Y}) = s_{y,x}^2 \left(\frac{1}{n} + \frac{(X - \bar{X})^2}{\sum_{i=1}^{n} (X_i - \bar{X})^2} \right) \qquad (1)$$

where $V(\log \hat{Y})$ is the variance of the mean surviving fraction after treatment with a certain X dose of radiation; $s_{y,x}^2$ is the variance from regression; n is the number of observations; $\bar{X}$ is the mean dose of radiation used; and $\sum_{i=1}^{n} (X_i - \bar{X})^2$ is the sum of the squares of the

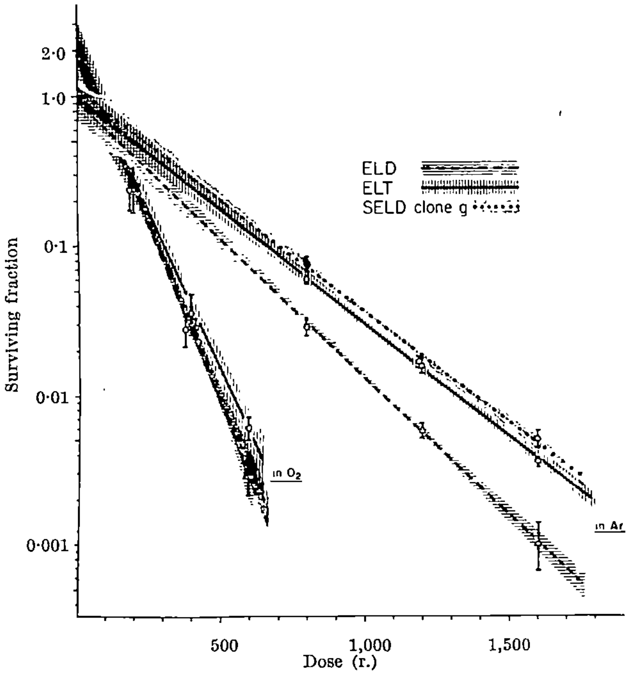

Fig. 1. Survival of cultures of the *ELD* ascites tumour line and of its *ELT* and *SELD* clone *g* sublines after exposure to different doses of X-rays in oxygen or argon. Open circles with vertical lines illustrate the means of surviving fractions in different experiments with the 95 per cent confidence limit. Oblique lines with shading indicate the statistical regression of survival with 95 per cent probability

deviations from the mean of the radiation doses used. Significant differences are apparent between the survival of *ELD*, on one hand, and of *ELT* or clone *g* on the other, after irradiation in argon, while the survival of the three cell lines is closely similar after irradiation in oxygen.

The numerical values of the slope constants and their standard error are presented in Table 1 (col. 7) together with the number of separate tests (col. 3) and the number of separate determinations of survival (col. 4) used for computation. By means of co-variance analysis[7] it can be calculated that the regression of *ELD* survival differs significantly ($P < 0{\cdot}01$) from the regression of *ELT* and clone *g* survival, respectively, after treatment in argon, but the differences are statistically insignificant after treatment in oxygen. The reciprocals of the slope constants are given in col. 10, and indicate the increment of radiation dose (D_0) which reduces the surviving fraction of the respective population by 37 per cent. The extrapolation numbers[8] with standard errors are tabulated in cols. 8 and 9. Using *t*-test analysis, it can be calculated that the extrapolation number of any of the cell lines after oxygen treatment differs significantly from the respective extrapolation number after treatment in argon ($P < 0{\cdot}001$ for *ELD* and clone *g*, and $P < 0{\cdot}05$ for *ELT*). The differences between different lines with regard to the extrapolation numbers in oxygen and in argon, respectively, are statistically not significant.

The results of the tests reported here are concordant in indicating that, in agreement with previous assays *in vivo*[2], differences in radiosensitivity do exist between the *ELD* strain and its selected sublines when irradiated under anoxic conditions. It can be calculated from the relationship between slope constants (col. 7, Table 1) that the sensitivity of clone *g* and *ELT* is 24 and 19 per cent less, respectively, than the sensitivity of the original *ELD*. The decreased sensitivity of clone *g* may be attributed to the protective effect of an increased cellular concentration of intrinsic, low molecular sulphydryls in this line, which has been previously estimated to be also 24 per cent higher than in *ELD*[9]. The reduction of the sensitivity of *ELT*, which has a sulphydryl concentration of the same magnitude as *ELD*[9], can be associated with the duplicated genome of this subline in comparison with *ELD*[2], and is in accordance with observations on the decrease of the sensitivity in other tumours with doubled chromosome sets[12,13]. The possible requirement to inactivate a larger number of sensitive sites has been considered to account for radio resistance in these cases[2].

The differences between the radiosensitivity of the cell strains demonstrated in anoxia were shown to be reduced to statistically insignificant variations when exposure to X-rays took place in oxygen. A reduction of sensitivity differences in oxygen, relative to those under anaerobic conditions, has been previously noted also when our[2] or other cell strains[10] were investigated in different test systems *in vivo*. It is conceivable that a similar 'masking' of the sensitivity differences by oxygen may explain the generally uniform survival of unrelated cultures treated in media equilibrated with air[12], that is, under conditions when cells exhibit full oxygen sensitivity[13]. If, as suggested by the data, the proportionately increased sulphydryl concentration accounts for the radio resistance of clone *g* in anoxia, then the disappearance of sensitivity difference between this strain and *ELD* in oxygen would be in agreement with the observation[14] of a considerable decrease of sulphydryl protection in an oxygenated medium.

The differences between the cell lines with regard to the relative radiosensitivities under aerobic and anaerobic conditions imply a differential enhancement of the effectiveness of radiation by oxygen. For *ELD*, *ELT* and clone *g*, oxygen enhancement ratios of 2·58, 2·79 and 3·16, respectively, can be calculated from the slope-constants. It can be inferred that oxygen does not act as a dose multiplying factor only, but there is also a qualitative difference in the lethal damage caused by irradiation in the presence or absence of oxygen. It has previously been suggested[2] that, in killing *ELD* and *ELT*, a genetic injury may prevail in connexion with anoxic X-irradiation and, conversely, a mainly non-genetic mechanism may be operative in connexion with aerobic treatment. This suggestion is in agreement with the postulate[1,15], based on observations made in experiments with micro-organisms, that DNA is more heavily involved in killing by X-radiation under anoxic as compared to aerobic conditions.

The extrapolation number of survival regressions, presented in cols. 8 and 9, Table 1, can be viewed as further evidence supporting the supposition of differential mechanisms of the radiation effect under aerobic and anaerobic conditions. Extrapolation to numbers larger than unity, found after treatment in oxygen, implies a sigmoid type of survival curve. This can be regarded as indicating that two or more damaging events, of the same or of different kind, must be accumulated for any lethal effect[8]. Conversely, extrapolation close to unity and the corresponding nearly exponential dose-effect relationship observed after treatment in oxygen-free argon denotes that a single damaging event may be sufficient for the loss of reproductive capacity. It would thus seem that the dose-effect relationship after anoxic treatment with sparsely ionizing X-rays is similar to that after treatment with densely ionizing radiations[13,16]. A reduction of the extrapolation number of the survival curve of cells treated by X-rays in an anoxic medium, as contrasted to treatment in a medium equilibrated with air, has been noted in our previous study[3] and by Humphrey *et al.*[17]. The opposite result has also been reported[18]. However, the significance of the difference between extrapolation numbers has yet to be established in these cases. Since the extent of recovery from radiation damage in connexion with fractionated X-ray treatment is related to the extrapolation number of the survival curves[19], such treatment of anoxic cells can be expected to result in a strong decrease or, possibly, absence of recovery, as in the case of densely ionizing radiations[13,16]. This expectation has been fully verified in experiments to be reported elsewhere, involving the exposure of *ELT* to fractionated X-ray doses in the presence or absence of oxygen.

PHYSICS

Propagation of a Gaseous Discharge in a Crossed Magnetic Field

THE application of a crossed magnetic field to an electron swarm moving under the influence of a uniform electric field enabled Townsend[1] to derive the high electron drift velocities, using a steady-state d.c. method without recourse to pulse techniques or oscilloscopes. From the measurement of the electron angular deflexion, θ^-, and making use of the expression, deduced by Townsend, $v_{\mathrm{T}}^- = \frac{E}{B} \tan \theta^-$, in which E and B are the crossed electric and magnetic fields, respectively, the drift velocity, v_{T}^-, was obtained in an elementary way. In this communication the early treatment is extended to include the numerous practical cases in which Townsend's secondary ionization coefficient comes into play in the full development of a gaseous discharge.

The mode of charge movement together with the crossed electric and magnetic field directions are shown in Fig. 1. An electron, or bunch of electrons, starts off instantly at point 0. As the electrons move in the transverse ($\bar{E}$) direction, they are deflected in the perpendicular ($e\bar{v} \times \bar{B}$) direction with velocity $v_{\perp}^-$. On reaching the point A (or A', A'' or A''', which corresponds to the end of the discharge region), sufficient positive ions have been produced which drift towards the cathode, in turn are deflected, though to a lesser extent on account of their mass, and strike the cathode surface to release a further burst of electrons. Thus, due to successive cycles, the discharge propagates in the perpendicular direction. Analysis of Fig. 1 shows that the propagation velocity, $\vec{v}$, is given by:

$$\vec{v} = v_{\mathrm{T}}^+ (\tan \theta^- + \tan \theta^+) \qquad (1)$$

in which v_{T}^+ is the transverse positive ion velocity and θ^- and θ^+ are the angular deflexions of the respective particles. No specification has been made as to whether the motion is governed by a few individual collisions or by multiple processes, and an important aspect is that the propagation velocity in this régime is independent of the discharge-length.

It has been observed[2] that the emission of an electron from the cathode on positive ion bombardment may be delayed for a time τ_s, called the site time, which may be comparable in duration with the ion transit time, τ_+. Taking this effect into account, the above expression becomes:

$$\vec{v} = v_{\mathrm{T}}^+ (\tan \theta^- + \tan \theta^+) \frac{\tau_+}{\tau_s + \tau_+} \qquad (2)$$

Thus the propagation velocity may vary over a wide range and is influenced by the properties of the gas and the nature of the electrodes.

In certain discharges, such as the column region, the regenerative process can be considered to take place continuously rather than in a stepped fashion, and a reconsideration of equation (1) shows that for this régime the propagation velocity is given by $v_{\perp}^-$ or $v_{\perp}^+$, depending on which ion component dominates the discharge. Thus, in general, the propagation velocity of a discharge will fall within the range:

$$v_{\perp}^- > \mu_{\perp}^+ (\tan \theta^- + \tan \theta^+) > v_{\perp}^+ \qquad (3)$$

in which the limiting velocities can be associated with columnar processes and the middle range corresponds to the cathode fall condition. The large differences between electron and positive ion velocities would lead to charge separation, and as this continuous mode may only be active in columnar regions, the presence of space charges can no longer be neglected and the concept of ion coupling[3] may have to be evoked.

It can be shown[4] for an electron swarm in hydrogen with a mean energy, $\bar{\varepsilon} = 3$ eV, that $v_{\perp}^- = 1{\cdot}5 \times 10^5 . \frac{E}{p} . \frac{B}{p}$ m/sec and $\tan \theta^- = 40 \frac{B}{p}$ for weak magnetic fields; also $v_{\mathrm{T}}^+ = \mu^+ \frac{E}{p}$ in which $\mu^+ = 96 \frac{\mathrm{m}}{\mathrm{sec}} \frac{\mathrm{cm}}{\mathrm{volt}}$ mm mercury[5], yielding $\vec{v} = 3{\cdot}84 \times 10^3 . \frac{E}{p} . \frac{B}{p}$ m/sec. Thus, the electron columnar velocity is 40 × larger than the stepped velocity of the discharge, which could correspond to that of the cathode fall. For $pd = 1{,}000$, $\left(\frac{E}{p}\right)_s = 20$ (ref. 6) and for $B = 0{\cdot}1$ Wb/m² and $p = 1{,}000$ mm mercury, $\vec{v} = 7{\cdot}68$ m/sec in agreement as to order of magnitude with observed gas discharge propagation velocities[7]. In the numerical derivation, the positive ion angular deflexion, θ^+, has been neglected. As no data are available for this quantity or $v_{\perp}^+$, there is a need for these to be measured, particularly as it is claimed[7-9] that θ^+ is the overriding quantity determining the propagation of an arc discharge. Useful information should also be gained from an investigation of the propagation velocity of a Townsend and glow discharge.

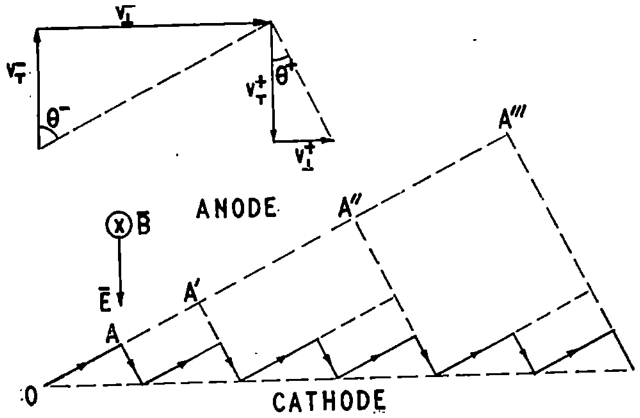

Fig. 1. Movement of electrons and ions of a Townsend discharge in a crossed electric and magnetic field

I thank Prof. G. W. Carter for granting facilities for this work; this preliminary work is sponsored partly by the Air Force Cambridge Laboratories under contract *AF* 61(052)–812 through the European Office of Aerospace Research, United States Air Force.

Porous Electron Emitters

In a recent publication[1] it was shown that the electron emission at zero field from a porous cathode was very dependent on the size of the pores and their emitting apertures. In particular a reduction in the slope of the Richardson plot, with increasing temperature, is to be expected because the space charge is constrained and can only exist near to the walls of the cavities. The resulting electron emission through apertures in the cavities is then in the form of 'quasi hollow' beams. Curvature of the Richardson plot commences when:

$$\frac{D}{2} = d = 1{\cdot}54 \times 10^{-2} T^{\frac{3}{4}} j_0^{-\frac{1}{2}} \mu\text{m}$$

where D is the diameter of the apertures, d is the distance from the emitting surface for which $\rho = \rho_0/4$; ρ being the charge density at a point distance r from the centre of a spherical cavity, ρ_0 the charge density at the cavity surface and j_0 the emission current density at zero field from the emitting surfaces. For spherical cavities:

$$R \gg d;\ \rho = \rho_0 \frac{\pi^2}{4} \frac{d^2}{(R + dc^{\frac{1}{2}})^2} \sec^2\left(\frac{\pi}{2} \frac{r}{R + dc^{\frac{1}{2}}}\right)$$

$$R \ll d;\ \rho = \rho_0$$

where R is the radius of the spherical cavities.

For normal oxide cathodes with a pore diameter of about 3 μm (ref. 2) $R \gg d$ at high temperatures. The emission from the cathode is considerably lower than would be the case from cathodes with a larger number of smaller pores having smaller emitting apertures. Therefore, the porosity of porous cathodes should, if possible, be controlled so that the condition $R \ll d$ will hold at the operating temperature, and the maximum possible emission should then be obtained.

Since the emission current density from an aperture is then the same as that which would be obtained from an equivalent area of exposed uncontaminated surface it is important that the exposed surface area of the cathode (including apertures) should be maximized. The additional emitting surfaces within the pores do not contribute to the overall emission from the cathode. The main advantage of a porous cathode is the fact that the emitting surfaces are more protected from contamination. If the coating is too thick then the temperature gradient existing in the matrix will make it necessary to heat the cathode base to a higher temperature for the same emission than would be the case for a thinner coating. On the other hand, the matrix should contain sufficient material so that evaporation effects do not unduly shorten the life of the cathode.

GEOPHYSICS

Shock Wave Propagation from a Nuclear Blast

Since the American nuclear explosion on July 9, 1962, at Johnston Island, independent reports from different parts of the world[1-5] have become available relating to the time of onset of some of its magnetic and earth-current effects. Apparently, in some places, the first impetus of the signal, almost instantaneously with the detonation, has not been noticed for some reason or other. The more intense impulse registered after 2 sec after zero time has been, perhaps, thought to be the first. At some other places, no mention is made of anything other than that received almost simultaneously with the blast. This note is to point out a substantial possibility of a hydromagnetic shock propagation due to the blast giving rise to almost simultaneous signal at different parts of the globe. Both the impulses, one at zero time, and the other 2 sec later, are treated from this point of view. It is, incidentally, pointed out that some of the auroral luminosity reported on this occasion might be attributed to the interaction of shock waves with the magnetosphere.

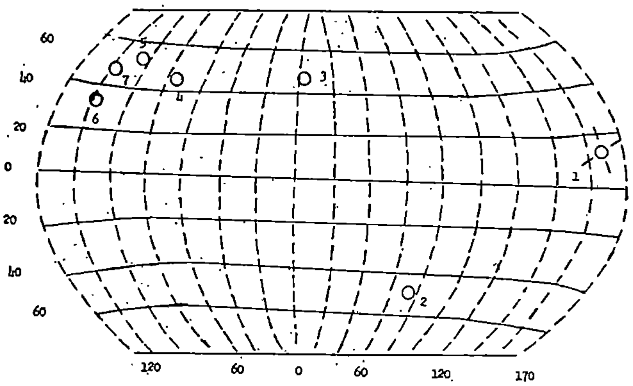

Fig. 1. Approximate locations of the different stations recording magnetic or earth-current or both effects due to the blast: 1, Johnston Island; 2, Kerguelen Island; 3, Chambon-la-Forêt; 4, Ottawa; 5, Prince Albert; 6, Los Angeles; 7, Penticton

Fig. 1 shows the approximate locations of the several stations of observation over different parts of the globe. From these places, either magnetic or earth-current effect or both have been reported. The reported times of onset of the effects at the respective stations are shown in Table 1. At some places, such as Prince Albert, Canada (53·2° N, 105·9° W.), mention is made only of the signal after 2 sec or so after detonation. In the Antarctic French station, Dumont d'Urville, the supposed first impulse has also been noticed only after 2 sec after zero time. However, other French stations (for example, Chambon-la-Forêt, France) did notice both the impulses referred to. The interesting feature is that, besides the first signal at almost zero time, the second, seen about 2 sec later, is also simultaneous at different parts of the globe. It may be recalled that, for *Argus* III explosion, the onset of some of the earth-current effects was registered within 1 sec interval over a range of 120° in longitude[6-8].

Table 1. Time of Onset of Signal due to Blast at Different Stations of the Globe

(Detonation time 09 : 00 : 09 U.T.)

Station	Signal arrival time (U.T.)	Ref.
	h min sec	
S.T.L., Los Angeles, U.S.A.	09 : 00 : 09 (±0·1 sec)	1
Penticton, Canada	09 : 00 : 09·1 (±0·1 sec)	3
Chambon-la-Forêt, France	09 : 00 : 08·8 (±0·2 sec) Also a second strong impulse 2 sec later	2
Kerguelen Island, South Indian Ocean	09 : 00 : 08·7 (±0·5 sec)	2
Prince Albert, Canada	~2 sec after detonation	5
Christchurch and Lauder, New Zealand (earth-potential)	0·2 ~ 0·5 sec after detonation	4
Ottawa, Canada (Rb vapour magnetometer)	09 : 00 : 12 (±2 sec)	3
Amberley, New Zealand (magnetic effect)	09 : 00 : 12 (±1·5 sec)	4

Considering the very small time in which the signal due to the blast is propagated over the globe, one would be led to think of either electromagnetic propagation, or a hydromagnetic shock, among others (for example, very fast neutron propagation[9]). We now consider the case of a hydromagnetic shock in the following.

For a shock front, it is known that the Rankine–Hugoniot equation must be satisfied, namely:

$$\frac{\rho}{\rho_0} = \frac{P(\gamma + 1) + P_0(\gamma - 1)}{P(\gamma - 1) + P_0(\gamma + 1)}$$

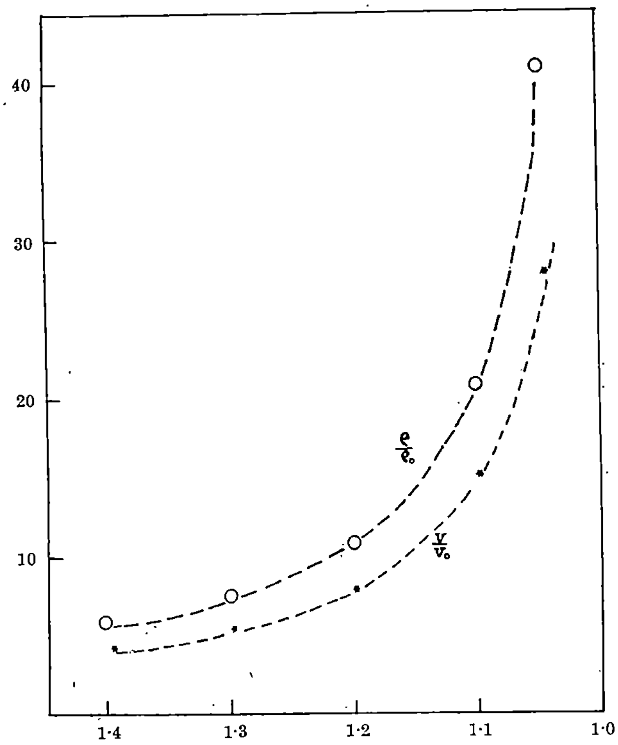

Fig. 2. Variation of shock Mach with the ratio of specific heats

γ is the ratio of specific heats; P_0, ρ_0, refer to ambient pressure and density respectively, before the arrival of the shock; and P, ρ are those behind the shock. For an explosion, $P \gg P_0$, and the Rankine–Hugonoit equation gives:

$$\frac{\rho}{\rho_0} \simeq \frac{\gamma + 1}{\gamma - 1}$$

Furthermore, it is known[3,10] that when a shock develops:

$$\frac{V}{V_0} = \frac{\rho}{\rho_0 \sqrt{2}}$$

where V_0 is the Alfven velocity in the gas at the front of the shock and V is the velocity behind the shock. Fig. 2 shows the ratios $\frac{V}{V_0}$ and $\frac{\rho}{\rho_0}$, for different values of γ. The ratio $\frac{V}{V_0}$, or the shock Mach, increases considerably as γ reduces towards unity. The ratio $\frac{V}{V_0}$ (or the shock Mach) can be considerably large depending on the intensity of the blast. Shocks arriving at the vicinity of the Earth having their origin, for example, in the solar blasts have a very high Mach number[11].

The hydromagnetic wave propagation speed at the heights of explosion, around 400 km, is of the order 150 km/s[12,13]. Even the crudest calculation on this basis gives up to 4,000 km/s for the shock propagation. Accordingly, it is obvious that a distance of the order of the diameter of the Earth can be traversed in 3-4 sec. It is interesting that this order of time is seen actually from the observations of the second impulse simultaneously at different places of the globe (stations 3 and 5, Fig. 1, for example).

The Alfven velocity can be as great as 500 km/s around 1,000 km altitude[12,13]. Simple calculations of shock speeds from this (without assuming any ducted propagation[14]) could give up to about 1/15 of the speed of light. If such a high-altitude propagation is possible at all, the simultaneity of the signal over different parts of the globe, almost instantaneously with the blast, is apparent. Auroræ have been observed[4] on this occasion at altitudes around 700 km. This is evidence in favour of the possible high-altitude propagation of the shock effect. In fact, it is possible that the observed auroral luminosity, in part at least, is by the interaction of the shock and the magnetosphere in a manner suggested earlier by Singer[11].

In conclusion, it is possible that both the first impulse due to the blast at almost zero time, and the second after 2 sec, could be attributed to shock propagation from the blast site. The second is perhaps due to propagation near the altitude of blast in space.

GEOLOGY

Magnetic Survey off the North Coast of Ireland

The geological relationships between the Pre-Cambrian and Caledonian folding and faulting systems of Scotland and Ireland to a large extent remain unresolved because of the unknown geology beneath the North Channel. A small but detailed (0·25–0·5 mile line spacing) total field magnetic survey off the coast of Donegal shows the presence of two faults which may well be of importance in the evaluation of these relationships. A simplified map of the magnetic results is shown in Fig. 1.

A strong scarp interpreted as Fault *A* is of some 500–600 gammas in amplitude, and a simple interpretation of this feature suggests that it is largely due to the almost vertical boundary of a large magnetic body at a depth to the top of 2–3,000′ below sea-level. The geographical linearity of the feature is indisputable and strengthens the fault interpretation, particularly as it is parallel to the known Caledonian faults of surrounding areas. Extension of the observed lineation to the north-east would take it west of Colonsay to south-east Mull, and to the south-west, into Mulroy Bay (marked MB on the inset map, Fig. 1). It is not suggested that this is necessarily a fault of major importance but it does indicate that the fault 'complex' of Donegal is probably continued to the north-east.

The fault marked *B* is in a complementary direction and divides two areas of particularly high magnetic values. Again a steep scarp is seen on the western group of anomalies following the line of the suggested fault, although the eastern group is less precisely bounded by this same direction. A detailed bathymetric survey (unpublished) reveals a linear scarp feature corresponding with the projected line and confirming its geological reality. The direction of movement of this fault can be suggested if it is assumed that the western and eastern groups of anomalies are equivalent, in which case the movement is dextral with a tear displacement of 5 miles. This is very similar to the fault mapped by McCallien in Inishowen and referred to by Pitcher, Elwell *et al.*[1]; nevertheless correspondence of the two groups is by no means certain.

Detailed sections show that in general there are two types of anomaly present, the large wave-length anomaly

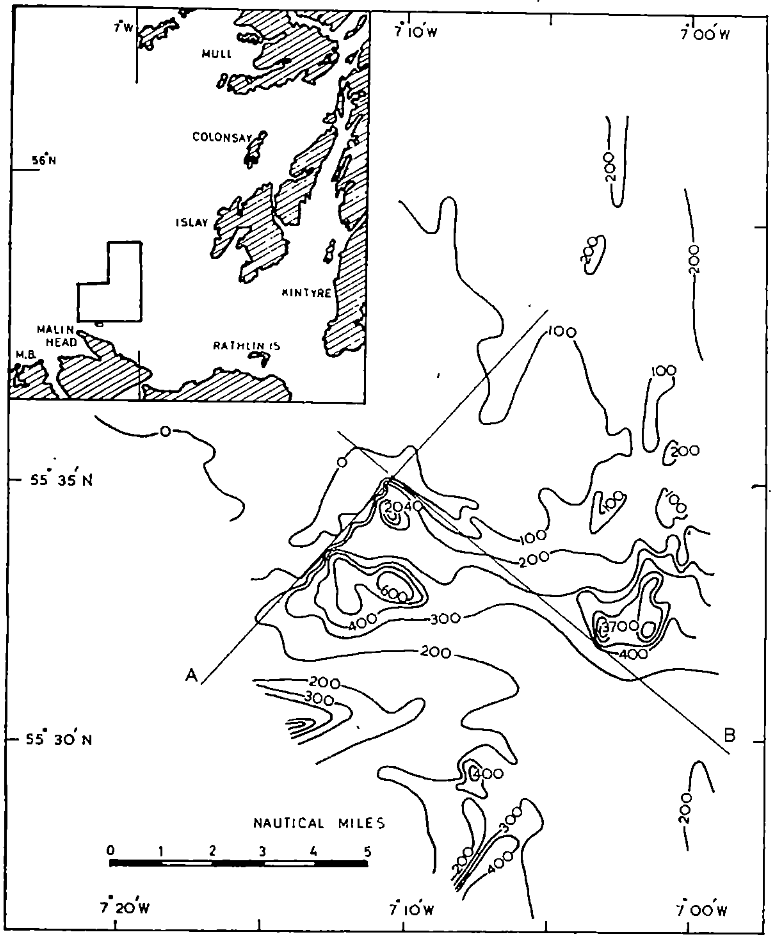

Fig. 1. Simplified total magnetic field contours of the survey area (regional removed). Values are given in gammas, zero value being the absolute value of the field at Eskdalemuir Observatory. Inset map shows the location of the survey area

which has been interpreted as referred to above, and narrower high-amplitude anomalies which are judged to be the product of smaller shallower basic bodies. The two types of anomaly have a similar geographical extent and the rocks are probably closely associated geologically, although there is some suggestion of a differential response to the north-west–south-east fault. The absence of any evidence of reversed magnetization gives preference to a non-Tertiary age for the rocks, but any closer identification is impossible at this early stage.

The survey was financed by the Department of Scientific and Industrial Research and made possible by the Hydrographic Office of the Royal Navy.

CHEMISTRY

Proton Magnetic Relaxation Times of Aqueous Tetra Alkyl Ammonium Halide Solutions

The effect of ionic solutes on the structure of water has been of considerable interest to electrochemists for a number of years[1-3]. Especially intriguing has been the anomalous behaviour of tetra alkyl ammonium salts. In order to account for the apparent molal heat capacities[2] and large negative entropies of hydration[1], Frank and Wen[2] have proposed that the apolar groups of these solutes exert a net 'structure-making' influence on surrounding water molecules in addition to the structural changes (that is, primary hydration) associated with the electric field of the ions. If the extent of structure-making is significant it might be expected that the correlation time, τ_c, for fluctuations of the local magnetic environment and hence the spin-lattice relaxation time, T_1, for water protons would alter appreciably[4].

In this communication we report spin-lattice relaxation times for water protons in solutions containing tetramethyl and and tetraethyl ammonium bromide over a wide concentration range. Relaxation times were measured by the spin-echo method and the individual T_1's are accurate to 5 per cent. Both solutes are observed to decrease T_1 with increasing concentration with the largest rate of decrease noted for the tetraethyl compound. A plot of the relaxation enhancement, $E = \frac{1}{T_1} - \frac{1}{T_1^0}$, versus molality is given in Fig. 1 and shows that the molal relativity, defined by the slope of the linear portions of the curve, is considerably greater for tetraethyl ammonium bromide 0·0825 sec^{-1} mole^{-1} kg than for tetramethyl ammonium bromide 0·0358 sec^{-1} mol^{-1} kg, and alkali halides[5,6]. A deviation from linearity in the E versus m plots is also noted to occur at lower concentration for tetraethyl ammonium bromide.

An enhancement of the relaxation rate in solutions of tetra alkyl ammonium salts may arise from three effects: (1) relaxation by the nitrogen-14 quadrupole; (2) intermolecular dipolar interaction with protons on the apolar groups; (3) increased intra- and intermolecular dipolar contributions due to structural changes of the solvent.

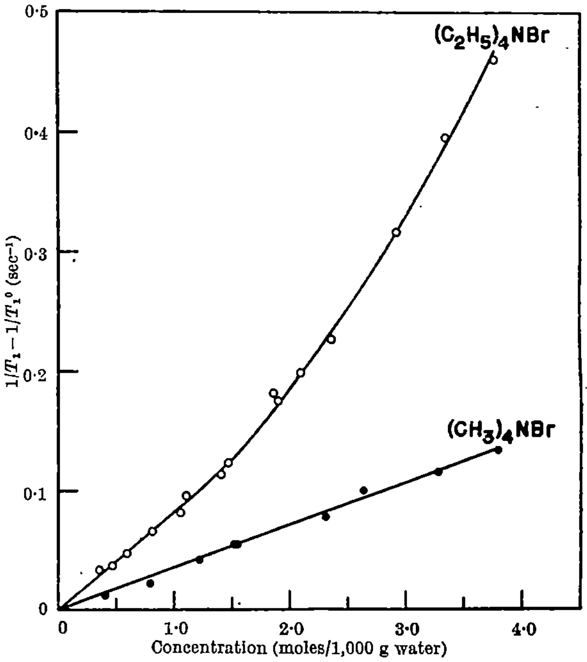

Fig. 1. Relaxation rates of water protons in solutions of tetramethyl- and tetraethyl ammonium bromides at 23° C. T_1^0 (pure water) = 3·10 sec; T_1 = relaxation time of water in solution

Of these the first possibility is unlikely because of steric hindrance by the alkyl groups while the second, although leading to a T_1 change in the correct direction, would not give rise to the large changes observed. The third and more likely possibility is an increase in the correlation times for rotation and diffusion of the water molecules with a resultant increase in both the intra- and intermolecular components of the relaxation rate[4]. Such an increase in τ_c would result if a significant fraction of the water molecules are partially immobilized in the vicinity of the apolar groups either by an increase in the 'ice-likeness' of water near the apolar groups or by the formation of partial clathrate hydrates about the apolar groups[7,8].

A qualitative interpretation of the E versus m curves can be given in terms of a simplified model in which the protons are assumed to occupy three distinct sites; that is, clathrate (or 'ice-like') water, hydrated Br^- ion and bulk water. The observed relaxation rate, $1/T_1$, is then given by the weighted average of the contributions from these sites and a preliminary calculation[5,9] shows that approximately 30 water molecules are involved in the ordered water layer about the $(C_2H_5)_4N^+$ ion. The ordering is accompanied by a ten-fold increase in the correlation time more than that in bulk water. In comparison, tetramethyl ammonium bromide is a much less effective structure-maker orienting less than 5 water molecules about the $(CH_3)_4N^+$ ion. The deviations from linearity observed in the E versus m curves at higher concentrations indicate that the three-site model is inadequate under these conditions.

Detection of Divalent Sulphur Compounds on Paper and Thin-layer Chromatograms

Recently a communication has been published by Thompson *et al.*[1] which describes a sensitive qualitative test for sulphoxides on paper chromatograms. The method is based on the reaction of sulphoxides with hydriodic acid to form iodine. C. De Marco[2] essentially extended the method of Thompson to certain other classes of partially oxidized sulphur compounds like sulphinic acids and sulphones. However, as explicitly stated in De Marco's communication, the Thompson test is of no direct use for the detection of other classes of organic sulphur compounds, especially the large number of substances containing divalent sulphur.

The publication of the two aforementioned papers[1,2] induced us to report a method used in this laboratory, which makes it possible to detect just those classes of organic sulphur compounds giving no reaction with hydriodic acid. Our method is based on the well-known oxidation of divalent sulphur compounds by periodic acid to sulphoxides, sulphones, sulphinic acids or derivatives thereof.

A positive reaction with neutral aqueous potassium (*meta*) periodate solution is given by aliphatic thiols, sulphides, disulphides, thioketones, thiamides and thioureas[3]. The aromatic thiols, sulphides, and disulphides usually do not react under these conditions[4]. However, these aromatic sulphur compounds will give satisfactory positive results with periodate in acetic acid solution, since an increase in the acidic strength of the oxidant favours the oxidation reaction[5,6].

The oxidation of compounds on paper chromatograms with periodate and the subsequent development of the unconsumed periodic acid with benzidine was originally used by Viscontini *et al.*[7], in carbohydrate chemistry, where the method indicates glycol groups. In this laboratory, the application of Viscontini's method for the detection of sulphur compounds was first observed while working with sugar–amino-acid complexes, the amino-acids having been DL-methionine and L-cystine. The method was later extended to aliphatic and aromatic thiols, sulphides and thioketones. As expected, thiophene and its derivatives give no reaction, the reason being the aromatic character of these compounds.

The technical details of the periodic acid oxidation of sulphur compounds are very similar to those given in the original application by M. Viscontini. The paper or the glass-plate is sprayed with a 0·1 per cent solution of sodium (*meta*) periodate in water or in 8 N acetic acid, respectively. After 4 min the colour is developed by spraying the paper with a 0·5 per cent solution of benzidine in *n*-butanol/acetic acid (4 : 1 v/v). Where oxidizable substances are present on the paper, the periodate is consumed and, afterwards, the colourless benzidine is not oxidized to the dark blue compound as on the rest of the paper. The final chromatogram shows white spots on a blue background.

The procedure is readily reproducible and sensitive. In the case of methionine the sensitivity is comparable to that of ninhydrin (5–10 µg). With aromatic sulphur compounds, the sensitivity is somewhat lower and depends on the aromatic residue (20–30 µg).

A preparative periodate oxidation of methionine was performed under the conditions of the development of the chromatogram. The main reaction product was methionine sulphoxide, with a minor amount of the sulphone present.

Production of Gallium by Continuous Electrodeposition from Acidic Solutions

As a means of production, electrolysis of gallium from only alkaline and not acidic solutions has been reported[1]. The principal difficulties reported using acidic solutions are: (*a*) poor current efficiencies; (*b*) formation of solid gallium oxychloride[2].

Reports of acidic gallium electrolyses[3,4] have shown it to be feasible, and the simple considerations leading to successful acidic gallium electrodeposition useful for large-scale production are outlined in this work.

Electrolysis of an aqueous solution of $GaCl_3$ using a molten gallium cathode and a graphite anode results in the sequence of events here.

(*a*) Aqueous dissolution of $GaCl_3$ yields an acidic solution (hydrolysis of a salt of a strong acid and weak base).

(*b*) Electrolysis begins with little or no hydrogen produced at the cathode with increasing amounts being generated as the process proceeds.

(*c*) The *p*H of the solution increases and, finally, GaOCl is precipitated and the gallium deposition current efficiency approaches zero.

(*d*) Addition of hydrochloric acid to $GaCl_3$ solutions reduces the gallium deposition current efficiency finally to zero.

For a 2 molar solution of $GaCl_3$ which has a *p*H of about 1, one calculates the following approximate values[5]:

$$E_{\text{Ga deposition}} \simeq 0 \cdot 51 \text{ V}$$

$$E_{\text{H}_2\text{ discharge}} \simeq 0 \cdot 50 \text{ (at molten gallium)}$$

Thus the reduction of Ga^{+3} and H^+ occurs with about equal ease and roughly in proportion to their relative concentrations. At first $[Ga^{+3}] \gg [H^+]$, but as the process proceeds this ratio is decreased and eventually is reversed when the *p*H is sufficiently high, causing the precipitation of GaOCl. The ratio is also decreased by the addition of hydrochloric acid.

A simplified overall reaction may be written:

$$(1 + \chi)GaCl_3 + \chi H_2O \xrightarrow{\text{electrolysis}} Ga + \chi H_2 + \frac{3 + 2\chi}{2} Cl_2 + \chi GaO^+ + \chi Cl^-$$

where, if χ becomes sufficiently large:

$$\chi GaO^+ + \chi Cl^- \rightarrow \chi GaOCl$$

In order to conduct a continuous electrodeposition of gallium from an acidic solution the Ga^{+3} concentration must be replenished and the acidity controlled to prevent the precipitation of GaOCl or the excessive formation of hydrogen at the cathode.

The Ga^{+3} can be replenished by the addition of a concentrated stock solution of $GaCl_3$. A measure of the amount of hydrochloric acid which must be added is the departure of the $[Cl^-]$ to $[Ga^{+3}]$ ratio of the solution from 3. The excess water may be removed by evaporation.

Utilizing the principles outlined, electrodeposition of gallium from about 1·5 l. of a 2 m $GaCl_3$ solution has been carried out indefinitely, producing 200–250 g of gallium in 6–7 h at current efficiencies of 60–80 per cent.

Many variations in automatic equipment are conceivable, but certain features are desirable:

(1) The graphite anode and molten gallium cathode areas should be such as to have current densities of 0·3–1 amp/cm² at each, and horizontally mounted parallel to each other at a distance that passes the required current (50–100 amp) at a potential of 12–16 V. It is advisable to perforate and channel the anode to facilitate the escape of chlorine gas.

(2) A cooling arrangement to keep the operating temperature within the range of 70°–90° is desirable.

(3) The only materials to be used that will come in contact with the gallium (III) chloride solution should be 'Pyrex', quartz and 'Teflon'. Other materials such as the 'Tygons' and 'Kel-*F*' are badly attacked, as are most metals.

Reaction between Molybdenum Disulphide and Water

MOLYBDENUM disulphide, MoS_2, undergoes oxidation in bulk at temperatures above 450° C, which may be demonstrated[1] by gravimetry. However, the substance must ordinarily be covered with a surface layer of oxide, since heating samples in a good vacuum leads to the evaporation of molybdenum trioxide. It is possible that such layers are involved in the frictional transients observed[2] when molybdenum disulphide is used as a lubricant in wet atmospheric environments. It is germane to inquire as to the origin of the oxide layers, and we wish to comment on the possible extent of the hydrolytic decomposition of molybdenum disulphide to yield hydrogen sulphide and molybdenum dioxide. Haltner found[2] that when an MoS_2 film, supported on certain metals, and particularly copper, was exposed to rubbing and shearing forces in a wet atmosphere, hydrogen sulphide could be detected. If no metal is present, however, the reaction appears to be different, for Cannon[3] found that the gravimetry of adsorption of water on fine particle molybdenum disulphide showed a strong and extensive irreversible interaction at 0° C. The latter also found that for very finely dispersed samples, if the specific surface area, rather than the mass of the solid, were taken as the extensive variable, the observed gravimetry conformed most closely with the reaction:

$$MoS_2 + H_2O \longrightarrow MoOS_2 + H_2$$

rather than a hydrolysis. While no search for hydrogen evolution was made in the earlier experiments[1–3], an examination of the thermal behaviour[3] of the putative oxysulphide indicated that a temperature of 350° C could be attained before any appreciable loss in weight was observed, and that this loss appeared to be associated with the formation of sulphur dioxide rather than hydrogen sulphide. It thus seemed likely that the reaction of molybdenum disulphide with water, studied in the absence of metals under conventional high vacuum conditions, was not a hydrolytic process of sulphide to oxide plus hydrogen sulphide, but a net oxidation. We have now extended the work to higher temperatures, with the following interesting results. The water adsorption work was repeated at 180° C, 20μ water vapour pressure, in quartz microbalance equipment like that described before[1,3]. The surface-area limited reaction with a permanent weight increase proportional to the specific surface area was seen again. 20 g samples of molybdenum disulphide ($\Sigma = 15$ m²/g) were then exposed to 20 mm water vapour at progressively higher temperatures between 200° and 500° C. The experiments were conducted in a quartz envelope to permit pre-degassing the solid. Pressures were monitored through the seven-day holding period of each of the experiments and gas samples were withdrawn for mass spectrometric study after one day each at various temperatures. The results are summarized in Table 1.

Table 1

Exp. No.	T° (C)	H_2O charge	Gas yield (mass spectrometric analysis) (S.T.P. c.c.) Condensable at 77° K	 Non-condensable at 77° K
1	200	5·5	Trace	Large amount of H_2
2	300	4·8	Trace	Large amount of H_2
3	400	4·0	0·29 (SO_2)	Trace
4	500	2·9	1·5 (SO_2)	Trace

No hydrogen sulphide was formed at any time during the sequence, and measurable amounts of sulphur dioxide only at temperatures in excess of 300° C. The first gas to be evolved from the samples was actually hydrogen, which was found in quantity in the gases withdrawn after a day at 200° C. The validity of the proposed equation is thereby supported.

It is also evident that any hydrolytic reaction which does occur must proceed through a mixed sulphide or at least involve the accommodation of the reactive metals cited (copper and iron) as ions in the molybdenum disulphide crystals.

These results confirm the interpretive extrapolation of the previous work[2], namely, that the action of water on MoS_2 is surface limited, and, in the absence of metals, consists primarily of an oxidative rather than a hydrolytic step.

A Kinetic Approach to the Nature of Ferrous Ions in Aqueous Solution

Ion association involving ferrous ions is difficult to detect by the usual techniques: direct spectrophotometry due to the low extinction coefficients of Fe(II) species and the possible presence of trace Fe(III) species with high extinction coefficients; conductivity due to the high concentrations of anions needed; electrometric measurements due to the easier formation of complex species involving Fe(III) ions. In these circumstances, kinetics can be useful in providing information on complex formation, if a suitable reaction can be found. Such a reaction to study the nature of Fe(II) ions is that of Fe(II) with hydrogen peroxide: with $[\mathrm{Fe(II)}]/[H_2O_2] > 2$, the reaction is first order in [Fe(II)] and first order in $[H_2O_2]$ (refs. 1 and 2):

$$\mathrm{Fe(II)} + H_2O_2 \rightarrow \mathrm{Fe(III)} + \cdot OH + OH^- \qquad (1)$$

$$\mathrm{Fe(II)} + \cdot OH \rightarrow \mathrm{Fe(III)} + OH^- \qquad (2)$$

We have found that the reaction is independent of ionic strength, independent of hydrogen ion concentration below *p*H 3 using perchloric acid and that the rate of the slow step (1) is dependent on the charge on the Fe(II) species. This allows the determination of the concentrations of free and of associated Fe(II) from the observed rate: and ionic strength effects must be due to the existence of equilibria between various Fe(II) species.

Hardwick[2] has shown, using ferrous sulphate in aqueous sulphuric acid, that the rate constant appears to depend on the concentration of sulphuric acid added when the latter is high. We have confirmed this, and carried out an investigation of the effect of added sulphate ions on the reaction of ferrous perchlorate with hydrogen peroxide in aqueous perchloric acid, following the rate spectrophotometrically by the formation of the Fe(III) species. Under these conditions, with added $[HClO_4] = 4 \times 10^{-3}$ M and ionic strength μ adjusted to 1·0 with added sodium perchlorate, the observed bimolecular rate constant k_0 increases with the concentration of added sulphate ions until a limiting value of k_0 is reached which is independent of the sulphate ion concentration, as shown in Table 1. This Table also shows that increasing the concentration of perchloric acid reduces the rate constant to the original value obtained in the absence of sulphate ions.

Table 1. Variation of k_0 with Sulphate Ions added at $\mu = 1·0$ and 25°C

$[SO_4^{2-}]$ M added	$[SO_4^{2-}]$ M corrected	$[HClO_4]$ M added	k_0 moles^{-1} l. sec^{-1}
—	—	0·0040	49·5
0·025	0·024	0·0040	53·0
0·050	0·0482	0·0040	57·9
0·075	0·0733	0·0040	60·0
0·10	0·0975	0·0040	65·7
0·125	0·122	0·0040	68·2
0·15	0·147	0·0040	73·0
0·20	0·197	0·0040	74·4
0·30	0·299	0·0040	72·5
0·35	0·347	0·0040	73·0
0·10	0·094	0·010	58·0
0·10	0·073	0·050	54·0
0·10	0·054	0·100	53·5
0·10	0·009	0·700	48·8

These results can be interpreted as follows:

$$SO_4^{2-} + H_3^+O \overset{K_b}{\rightleftharpoons} HSO_4^- + H_2O \qquad (3)$$

$$SO_4^{2-} + Fe^{2+} \overset{K_c}{\rightleftharpoons} FeSO_4 \qquad (4)$$

$$Fe^{2+} + H_2O_2 \xrightarrow{k_1} Fe^{3+} + \cdot OH + OH^- \qquad (5)$$

$$FeSO_4 + H_2O_2 \xrightarrow{k_2} FeSO_4^+ + \cdot OH + OH^- \qquad (6)$$

$$\mathrm{Fe(II)} + \cdot OH \rightarrow \mathrm{Fe(III)} + OH^-$$

with $k_2 > k_1$: Fe^{2+} is assumed to be hexahydrated ferrous ion and all other ionic species are assumed to be hydrated. When sulphate ions are added the species $FeSO_4$ is formed via equation (4), which produces an increased rate through equation (6). The presence of a possible species $FeHSO_4^+$ is rejected under these conditions due to the effect observed on increasing the acidity, as recorded in Table 1. If [Fe(II)] is the total concentration of ferrous species,

$$\begin{aligned} d[\mathrm{Fe(III)}]/dt &= 2k_0[\mathrm{Fe(II)}][H_2O_2] \\ &= 2k_1[Fe^{2+}][H_2O_2] + 2k_2[FeSO_4][H_2O_2] \end{aligned}$$

and it can be shown that:

$$k_0 = \frac{k_1 + k_2K_c[SO_4^{2-}]}{1 + K_c[SO_4^{2-}]} \qquad (7)$$

where $K_c = [FeSO_4]/[Fe^{2+}][SO_4^{2-}]$. If $K_c[SO_4^{2-}] < 1$, this reduces to:

$$k_0 = k_1 + k_2K_c[SO_4^{2-}]$$

When k_0 is plotted against $[SO_4^{2-}]$ a straight line is obtained (Fig. 1*a*): $[SO_4^{2-}]$ was corrected for the formation of HSO_4^- ions by using a value of K_b at $\mu = 1$ interpolated from the data of Reynolds and Fukushima[3]. If the reactive species in the presence of sulphate ions is $Fe(SO_4)_2^{2-}$, a plot of k_0 against $[SO_4^{2-}]^2$ should give a straight line: Fig. 1*b* shows that such a plot is a curve, and therefore $Fe(SO_4)_2^{2-}$ is not formed under these conditions. From the slope of Fig. 1*a*, using the value of k_2 obtained from the limiting value of k_0, an approximate value of K_c can be obtained. This value was substituted back into the full expression (7) and $k_0(1 + K_c[SO_4^{2-}])$ plotted against $[SO_4^{2-}]$, and a further value for K_c obtained from the slope of the straight line (Fig. 2). By re-substituting this

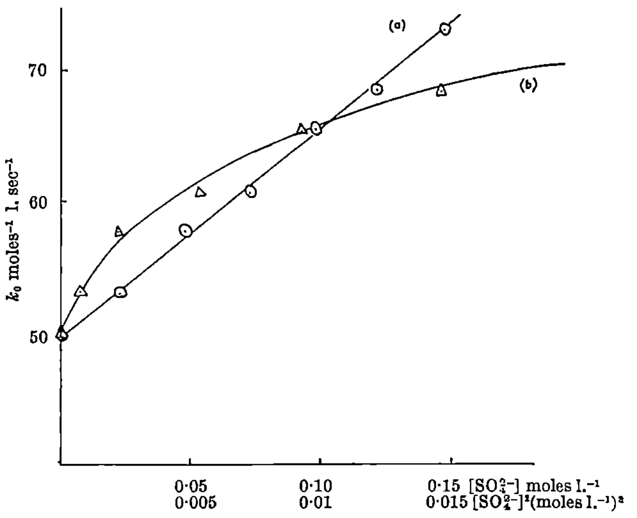

Fig. 1. Plot of k_0 versus (*a*) $[SO_4^{2-}]$ and (*b*) $[SO_4^{2-}]^2$

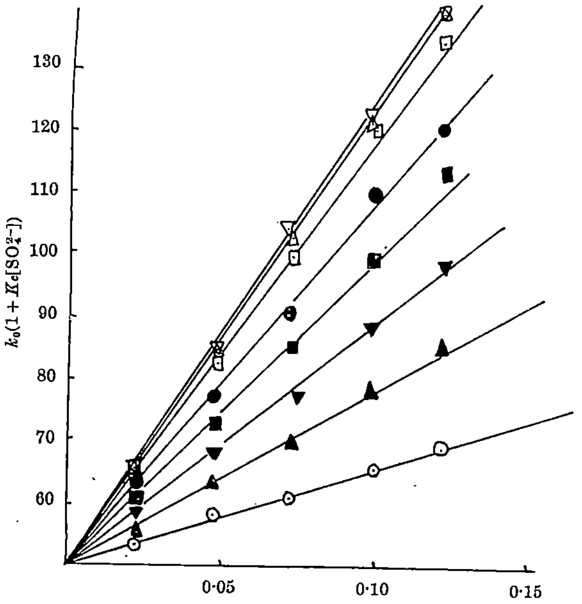

Fig. 2. Plots of k_0 $(1+K_c[SO_4^{2-}])$ versus $[SO_4^{2-}]$ with converging values of K_c as follows: ⊙, 2·06; ▲, 3·92; ▼, 6·60; ■, 8·10; ●, 8·75; ⊡, 9·30; △, 9·90; ▽, 10·20

value and replotting in this way until successive plots converge an accurate value was obtained for K_c: these plots are shown in Fig. 2. By this method for $FeSO_4$, $K_c = 10{\cdot}2$ moles^{-1} l. at $\mu = 1{\cdot}0$ and 25° C. These results can be compared with $K_c = 1{\cdot}1$ at $\mu = 1{\cdot}0$ and 30·5° C suggested by Huffman and Davidson[4] to explain their kinetic data on the autoxidation of Fe(II) in aqueous sulphuric acid and $K_c = 0{\cdot}61$ for $FeHSO_4^+$ and $K_c = 1{\cdot}7$ at room temperature used by Beukenkamp and Herrington[5] to explain their ion-exchange data involving ferrous ions in sulphuric acid without control of ionic strength.

Table 2. Values of k_2 and K_c at 25° C

Fe(II) species	μ	k_2 moles^{-1} l. sec^{-1}	K_c moles^{-1} l.
Fe^{2+}	1·0	$(k_1=)$49·5	—
$FeCl^+$	1·0	68·7	4·45
$FeSO_4$	1·0	74·4	10·2
$FeHP_3O_9$	1·0	91·5	9·42
$FeP_3O_9^-$	1·0	123·2	13·4
$FeCl^+$	4·0	66·2	10·3

Similar detailed kinetic investigations of the reaction of ferrous perchlorate with hydrogen peroxide in aqueous perchloric acid with added chloride ions and trimetaphosphate ions show in each case an increase in k_0 to a limiting value independent of the concentration of the anion. These results have been interpreted in an analogous manner to the above for the $FeSO_4$ species, and values of k_2 and K_c for the species $FeCl^+$, $FeP_3O_9^-$ and $FeHP_3O_9$ are given in Table 2. These data, when combined with that for $FeSO_4$ and k_1 for Fe^{2+} ions in perchlorate media alone, indicate that, as expected on simple electrostatic considerations of electron transfer, the ability to abstract an electron from Fe(II) is increased by a decrease in the positive charge, with a further increase on changing to a negative charge, but comparison of values of k_2 for $FeSO_4$ and $FeHP_3O_9$ shows that the size of the anion has some influence. The association constant K_c increases with an increase in the negative charge on the anion, as expected on a simple electrostatic picture. Experiments with $[ClO_4^-] = 8$ M and $[NO_3^-] = 5{\cdot}2$ M indicate that, in these conditions, the association of ferrous ions with perchlorate ions and nitrate ions does not occur. The data for $FeCl^+$ in Table 2 show, as expected, that an increase in ionic strength has no effect on k_2 but changes K_c.

This work will be described in detail elsewhere, together with further work on other anions and the effects of the variation of temperature. One of us (M. A. S.) thanks the Colombo Plan for a scholarship.

BIOPHYSICS

Electron Paramagnetic Resonance in Single Crystals of Cupric Insulin

The binding of divalent metal ions to insulin has been the subject of several investigations, both chemical and physical in nature[1-6]. In describing here the application of electron paramagnetic resonance (EPR) spectroscopy to this problem, we wish to emphasize the richness of the data obtainable from orientation investigations of single crystals. This information is of the following kinds: (1) the number of distinct magnetic centres; (2) the orientation with respect to the crystal axes of the symmetry axes of the magnetic centres; (3) the symmetries of the protein environments of the magnetic centres, and the ground-states of the transition metal ions; (4) the delocalization of the electrons in metal ion–protein bonds; (5) identification of protein atoms bound to metal ions when the former have nuclear magnetic moments; (6) an estimate of the distance between metal ions.

Single crystals of ferrimyoglobin and hæmoglobin have been investigated by EPR[7,8], but no cuproprotein crystal has.

Orientation investigations require the crystal to be mounted in a resonant cavity so that knowledge of the directions of the crystal axes is retained; then spectra are taken at many angles of the magnetic field with respect to the crystal axes. Protein crystals pose special problems. They are difficult to prepare in large size and are magnetically dilute, whence a sensitivity requirement is imposed. The crystals are fragile, which makes handling difficult. If the protein must be cycled between room and cryogenic temperatures in order to re-position the crystal, the EPR spectra progressively deteriorate.

We have developed a fused-quartz mount which automatically determines the initial orientation of the crystal. A gear train permits remote orientation of this mount and hence, in conjunction with rotation of the magnet, provides access to all orientations of crystal relative to field and eliminates temperature cycling and remounting. The resonant cavity, a totally enclosed, gold-plated, fused-quartz structure (half-wave-length), is immersed directly in the refrigerant. A 100-kc/s field modulation is used.

The low noise and high sensitivity of this apparatus are demonstrated by the photographically reproduced record of Fig. 1*A*, taken from a single cupric insulin crystal (at 90° K) containing 5×10^{16} spins. The signal-to-noise ratio of this spectrum is about 50 : 1 for a 1 sec integration time and a modulation field of two gauss. The number of detectable spins for a signal of width ΔH is 1×10^{11} ΔH at optimum modulation field strength[9]. The practicality of the apparatus is indicated by the fact that a complete orientation investigation (more than 50 spectra) was performed at 90° K within 48 h without removing or disturbing the crystal (though rotating it through many angles).

Cupric pig insulin crystals were prepared and analysed at Novo Terapeutisk Laboratorium A/S, Copenhagen, by the method of Schlichtkrull[5]. These rhombohedral crystals

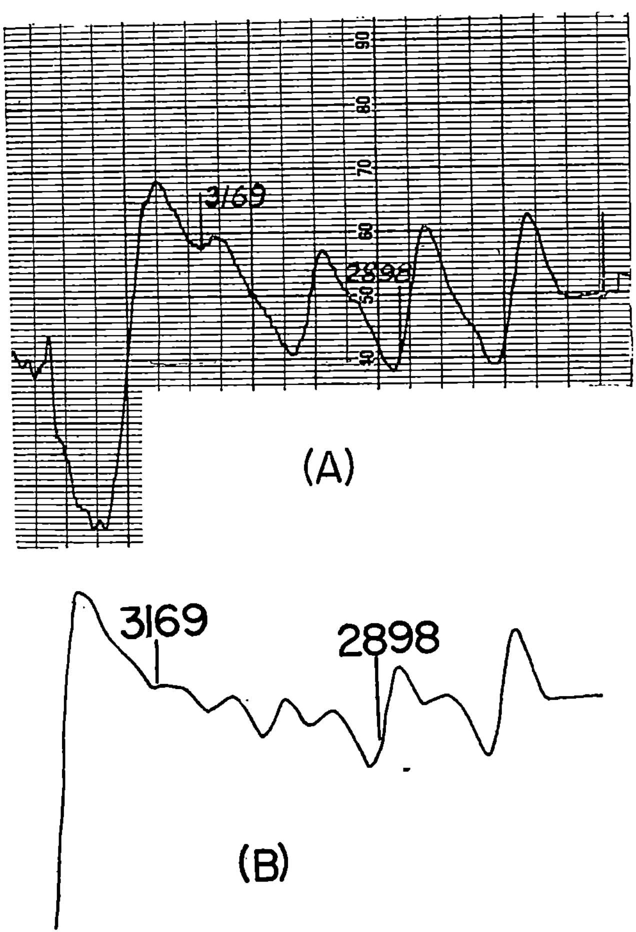

Fig. 1. Cupric insulin crystal at 90° K. (*A*), $\varphi=0°$, $\theta=56\cdot6°$, $\nu=9\cdot494$ Gc/s; (*B*), $\varphi=-20°$, $\theta=55\cdot0°$, $\nu=9\cdot541$ Gc/s

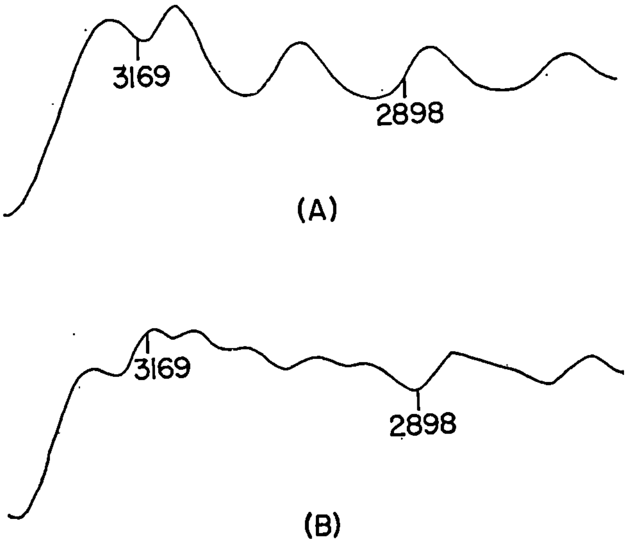

Fig. 2. Cupric insulin crystal at 295° K. (*A*), $\varphi=0°$, $\theta=56\cdot6°$; (*B*), $\varphi=-20°$, $\theta=56\cdot6°$; $\nu=9\cdot492$ Gc/s in (*A*) and (*B*)

contain two cupric ions per 36,000 molecular-weight unit cell (6 Sanger units), and, along with insulin crystals similarly prepared with other divalent metal ions of the 3*d* group, are isomorphic with the diamagnetic zinc crystals.

Spectra from a single Cu^{++} insulin crystal at room temperature are shown in Fig. 2. θ and φ are spherical co-ordinates, with the three-fold symmetry axis of the crystal the polar axis. For θ = 90°, φ = 0°, *H* is perpendicular to a crystal edge. The spectrum of Fig. 2*A* was taken with *H* in the direction of the highest *g* value observed (peaks appearing at minimum *H*). There are two other directions giving the same spectrum. The spectra do not change very much as θ is varied from this position, but become quite different—peaks are only partially resolved (Fig. 2*B*)—as φ is changed. When only room temperature spectra were available, we believed this direction and the other two like it to be the $g_{\max}$ principal axes of three magnetic sites.

The spectra in Fig. 1 were taken at 90° K with the crystal in the same orientations as in Fig. 2. Fig. 1*A* is similar to Fig. 2*A* but for a reduced line-width. The direction shown in Fig. 1*B* now shows well-resolved peaks. The crispness of the spectra taken at 90° K makes it possible to observe the movement of the separate peaks as φ is changed and so see that the directions originally believed to be $g_{\max}$ of three ions were each actually a superposition of peaks of (at least) two ions. Careful investigations indicate that the maximum *g* values of these ions are identical and lie at φ = about ± 15° from the original directions.

Due to the large line-widths and overlapping lines present even at 90° K, the detailed magnetic characteristics of Cu^{++} insulin must be determined by a digital computer programme we have developed. Although the computer analysis of the room temperature and 90° K spectra is not complete, some general features of our data are clear:

(1) The spectra are completely reproducible from crystal to crystal.

(2) The magnetic symmetries exhibited by the crystals are consistent with the known space group of insulin, $R3$ (ref. 1).

(3) Although there are 2 Cu^{++} per unit cell (on the average), there are 6 magnetic sites per unit cell. These sites appear to differ only in the orientation of the ligands about the ions. While the existence of 6 sites has not been predicted by physical chemical measurements[3,4], it is consistent with the data of Schlichtkrull, which show

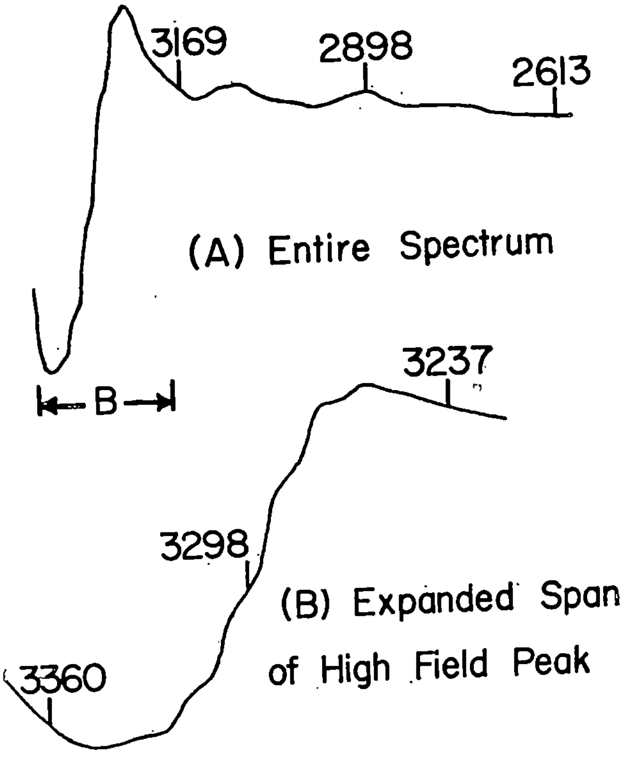

Fig. 3. Cupric insulin crystal at 90° K. $\varphi=135°$, $\theta=88\cdot0°$, $\nu=9\cdot532$ Gc/s

that a maximum of 6 atoms can go into a 36,000 molecular-weight unit[6].

(4) In certain directions (Fig. 3) the high-field absorption is observed to be modulated by five sub-peaks. This is the interaction of the cupric ion with its ligands. In terms of co-ordinating groups available in the protein, the only likely possibility is that the metal ion is bound to two magnetically equivalent nitrogen atoms (nuclear spin = 1), in agreement with the suggestion of Tanford and Epstein[3] and contrary to the implication of Marcker[4].

When the computer analysis is complete and results are available from present experiments at 20° K, a complete report will be submitted for publication.

This work was supported by U.S. Public Health Service research grant *GM*-09256 from the Division of General Medical Science.

We thank Dr. Jørgen Schlichtkrull, Novo Terapeutisk Laboratorium A/S, Copenhagen, for his assistance in this work.

Molecular Geometry of Androsterone

THE structure of androsterone, $C_{19}H_{30}O_2$ (Fig. 1), the first male sex hormone to be discovered, was determined recently by High[1] by vector coincidence methods. The space group of this compound is $P2_1$; the unit cell constants are $a = 9{\cdot}56$ Å, $b = 7{\cdot}90$ Å, $c = 11{\cdot}78$ Å, $=111{\cdot}36°$, $Z = 2$, and the measured density equals 1·164 g cm^{-3}. High's atomic positional parameters have been used to calculate the quantitative geometry of the androsterone molecule as follows. The final monoclinic fractional co-ordinates (x, y, z) were converted to Cartesian co-ordinates in Å (p, q, r) using the expressions $p = a_0x + c_0z \cos \beta$, $q = b_0y$, and $r = c_0z \sin \beta$, where a_0, b_0 and c_0 are taken in the Donnay setting ($a_0 = 11{\cdot}78$ Å, $b_0 = 7{\cdot}90$ Å, $c_0 = 9{\cdot}56$ Å). The Cartesian Å co-ordinates were used, in turn, to compute a series of 'best' planes (Table 1) to which various geometrical features of the molecule could be referred, namely, the root mean square distances of atoms from the 'best' planes (Table 2), the perpendicular distance of individual atoms from the 'best' planes (Table 3), and the angles between the 'best' planes and various sub-portions thereof (Table 4). The 'best' plane calculations were performed on an IBM 1620 computer using the 'best' plane 'Fortran' programme of Harris and Harker[2].

The degree of planarity, as indicated by the root mean square (r.m.s.) distance of atoms from the 'best' planes (Fig. 2), improves as one considers smaller and smaller portions of the androsterone molecule. A clear demonstration of this is given by the gradual decline of the r.m.s. distances of atoms from: (1) the entire androsterone molecule ($\sqrt{\lambda} = 0{\cdot}773$ Å); (2) the steroid nucleus plus the angular methyl groups ($\sqrt{\lambda} = 0{\cdot}625$ Å); (3) the steroid nucleus by itself ($\sqrt{\lambda} = 0{\cdot}269$ Å).

* Atoms lying between the origin of the unit cell and the plane have a negative value. Those on the opposite side of the plane from the origin have a positive value.

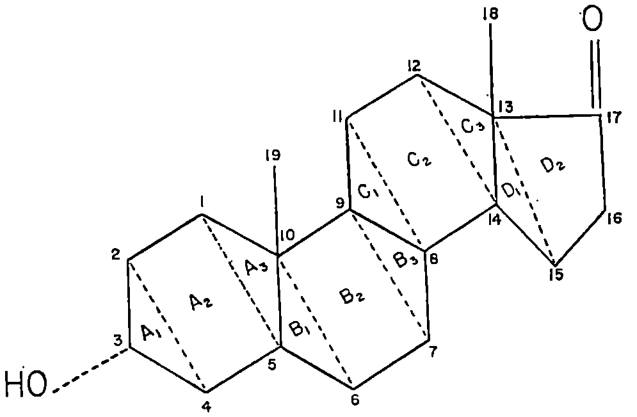

Fig. 1

If one considers the divisions and subdivisions of the steroid nucleus, it is apparent that the same relationship holds. The r.m.s. distances of atoms ($\sqrt{\lambda}$) from rings *A*, *B*, *C*, and *D* are 0·227, 0·233, 0·232 and 0·197 Å respectively. Atoms in the sub-portions of the ring system have the following r.m.s. distances: (1) those for *A*2, *B*2, *C*2 and *D*2 equal 0·001, 0·015, 0·008 and 0·055 Å, respectively; (2) those for the major-ring-division joins *A*3*B*1, *B*3*C*1 and *C*3*D*1 equal 0·030, 0·021 and 0·077 Å, respectively.

Information concerning side group configuration can be obtained from consideration of the perpendicular distances of individual atoms from the 'best' planes (Table 3). The hydroxyl oxygen attached to *C*3 is coplanar with respect to ring *A*. This is illustrated by the fact that the perpendicular distance of O_3 from the 'best' plane *A* is 1·634 Å, a distance which is nearly equal to the sum of the C_3–O_3 bond-length (1·444 Å) and the perpendicular distance of O_3 (0·199 Å) from 'best' plane *A*. The perpendicular distance of the keto oxygen (O_{17}) to the 'best' plane of ring *D* is 0·540 Å.

Table 4. DIHYDRAL ANGLES OF ANDROSTERONE

Planes	Dihedral angles (deg.)
AB	172
BC	175
CD	172
*A*1*A*2	133
*A*2*A*3	131
*A*3*B*1	175
*B*1*B*2	127
*B*2*B*3	132
*B*3*C*1	176
*C*1*C*2	132
*C*2*C*3	129
*C*3*D*1	168
*D*1*D*2	137

The C_{18} angular methyl group is axial with respect to ring *D* as evidenced by the fact that the perpendicular distance of C_{18} (1·804 Å) to the 'best' plane *D* is equal to the sum of the C_{13}–C_{18} bond-length (1·548 Å) and the perpendicular distance of C_{13} (0·257 Å) from 'best' plane *D*.

The C_{19} angular methyl group is axial with respect to ring *A* and ring *B* respectively. The perpendicular distance of C_{19} from 'best' plane *A* is 1·782 Å; from 'best' plane *B* it is 1·793 Å. In each case this distance is the sum of the C_{10}–C_{19} bond-length (1·541 Å) and the perpendicular distance of C_{10} to the 'best' planes (0·247 Å and 0·258 Å respectively).

That the angular methyls are on the same side of the molecule is shown by the agreement of signs (both negative) prefixing the perpendicular distances of the methyls to the plane of the entire molecule.

Consideration of the dihedral angles (Table 4) reveals the following additional steric information about androsterone.

(1) The *A*, *B* and *C* chairs are symmetrical as illustrated by their similar dihedral angles (*A*1*A*2 = 133°, *A*2*A*3 = 131°; *B*1*B*2 = 127°, *B*2*B*3 = 132°; *C*1*C*2 = 132°, *C*2*C*3 = 129°).

(2) The interchair which joins *A*3*B*1 and *B*3*C*1 is almost planar (dihedral angles equal 175° and 176°, respectively). The joint between chair *C* and ring *D* is less planar (*C*3*D*1 = 168°). The r.m.s. distances of atoms involved in the *A*3*B*1, *B*3*C*1 and *C*3*D*1 interchair joints substantiate these data (0·030, 0·021 and 0·077 Å, respectively).

BIOCHEMISTRY

Optical Rotatory Dispersion of Liver Alcohol Dehydrogenase and its Complexes

WE have recently reported that the stability of liver alcohol dehydrogenase (LADH) towards denaturing agents, such as heat, hydrogen or hydroxyl ions, is greatly enhanced in the binary complexes with NADH* or NAD, and still more in the ternary complexes with coenzymes and inhibitors[1]. The reaction velocity of the free SH groups with PCMS was greatly reduced by complex formation, and the solubility of the enzyme in phosphate buffer increased considerably.

Furthermore, X-ray diffraction studies on crystals of LADH and its complexes showed definite differences between LADH or its binary complexes and the ternary complexes[2]. It was therefore of interest to study the optical rotatory dispersion of LADH and its complexes in solution, especially since the changes indicated here could very well be due to changes in α-helix content of the protein moiety. Even if the strict numerical relations between optical rotatory dispersion and α-helix content have so far been established only for polypeptides, the relative changes we are interested in here can be interpreted with considerable confidence.

The LADH used was prepared essentially according to Dalziel[3] with the omission of the chromatographic steps. The quality of the coenzymes used has been described previously[1]. The optical rotatory dispersion spectra were run on a partly modified Rudolph recording spectropolarimeter. The effective wave-length scale was recalibrated for the slit width used. The temperature was on all occasions 25·0° C. The solvent was a sodium phosphate buffer of ionic strength 0·1 and *p*H 7·0. The refractive index of the solvent was determined as a function of wave-length and the values obtained were used for calculation of Moffitt–Yang plots. The λ_0 value used was 2120 Å, which gave linear plots on all occasions.

The presence of NADH and NAD molecules respectively in the enzyme solutions produces a series of Cotton effects characteristic for the complexes formed[4]. These effects were located at the absorption maxima of the coenzymes. The effects at the NAD band at 260 mμ and the NADH bands at 260 and 340 mμ could be measured directly. Additional Cotton effects can be assumed to exist at lower wave-length. The partial rotatory contributions from these bands can be expressed as a series of correction terms. The magnitude of the contributions can be estimated and the measured values corrected, thus making it possible to calculate the Moffitt–Yang parameters. The detailed calculations will be published separately.

---

* Abbreviations: NAD, nicotinamide adenine dinucleotide; NADH, reduced nicotinamide adenine dinucleotide; PCMS, *p*-chloromercuribenzene sulphonate.

Table 1. Moffitt–Yang Parameters of LADH Solutions at 25° C $\lambda_0 = 2120$ Å

	LADH in buffer	LADH 1·00% NADH 417 μM	LADH 1·00% NADH 300 μM isobutyramide 16·6 mM	LADH 1·00% NAD 330 μM pyrazole 8·3 mM
b_0	-95 ± 15	-119 ± 10	-185 ± 10	-180 ± 10
a_0	-30 ± 15	-49 ± 10	-65 ± 10	-60 ± 10

The estimated errors are mainly due to differences between different batches of enzyme. The error in b_0 values due to instrumental error could be estimated from repeated runs of the same solution. It never exceeded ± 5 units. The changes in a_0 values cannot be interpreted in detail as, in addition to the usual complications, it contains additional terms. The b_0 values can, on the other hand, be directly correlated with the protein part of the LADH. It is remarkable that the presence of NADH, which results in the appearance of the whole system of Cotton effects, has very little influence on b_0. In the case of ternary complexes, additions of pyrazole or isobutyramide, which do not introduce further Cotton effects in the long wave-length region, give rise to considerable increases in b_0 values. The magnitude of the increase is the same for the ternary complexes LADH–NADH–isobutyramide and LADH–NAD–pyrazole. Thus the evidence at hand strongly suggests that a definite change of protein conformation takes place when the ternary complex is formed. The absence of definite changes in b_0 for the binary complex does not of course imply that the protein is entirely unchanged, but only that the type of change to which b_0 values are sensitive is small or absent. As for the interpretation of the nature of the change visualized by the increase of b_0, the tentative assumption can be made that it represents an increase of α-helix content of the enzyme, or more correctly, an increase in any system of identical and weakly interacting groups[5].

Stability of Bilirubin

CRYSTALLINE bilirubin changes with time as noted by Küster[1]. Newly recrystallized, it dissolves immediately and completely in chloroform. With aged preparations, when dissolved at room temperature, a certain amount of insoluble substance is observed which dissolves within a few seconds when boiled under reflux. This must be due to either an isomerization from bilirubin to dihydrobiliverdin—a displacement of the π electrons from the vinyl to the central methylene bridge[2]—or a transition between two crystalline phases, the less soluble having the highest thermodynamical stability.

Dissolved in pure chloroform, bilirubin is stable for hours even in diffuse daylight as a result of the intramolecular hydrogen bonds which stabilize the central methylene bridge[3].

Alkaline solutions of bilirubin, on the contrary, are very labile depending on alkalinity, the presence of metal ions and light. The intramolecular hydrogen bonds are broken and the central methylene bridge is adapted to dehydrogenation either by isomerization[2] or oxidation. This process is catalysed by metals as shown in Fig. 2 by adding zinc acetate or a metal-complexing reagent as EDTA (ethylenediamine tetraacetic acid). Metals are bonded to the pyrrolnitrogens in biliverdins[4] and consequently, in the presence of metals, the more linear bilirubin molecule is forced into the circular biliverdin (Fig. 1), that is, a double bond is introduced into the central bridge.

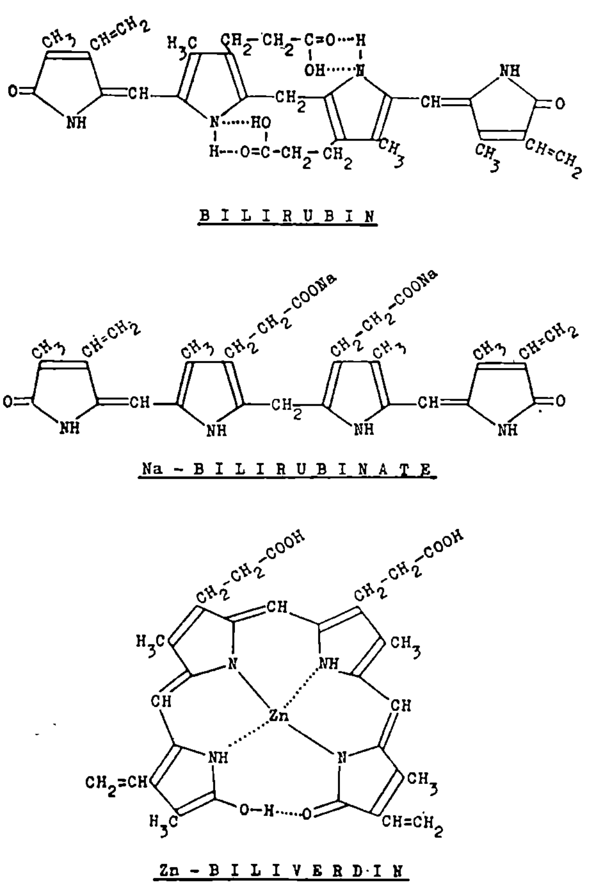

Fig. 1

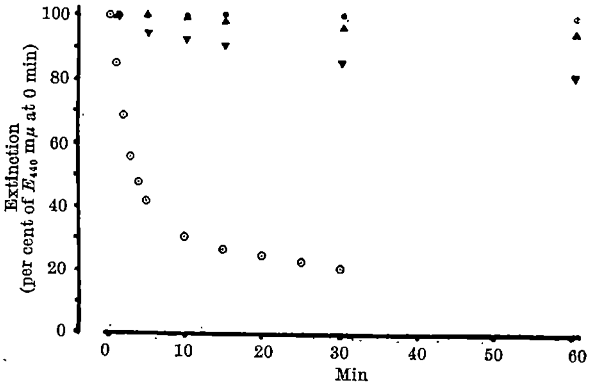

Fig. 2. ●, 2 g Na_2CO_3 and 2·5 mM EDTA/l. (pH 11·0); ▲, 2 g Na_2CO_3/l. (pH 11·0); ▼, 10 g Na_2CO_3/l. (pH 11·3); ⊙, 2 g Na_2CO_3/l. + zinc acetate (tracer quantity)

Alkaline solutions are stabilized also by human serum probably because of a re-establishment of the intramolecular hydrogen bonds as shown by the 'indirect' Hijmans van den Bergh's reaction observed with such solutions.

Daylight facilitates electron displacements and bilirubin absorbs strongly in light. In alkaline solutions the extinction coefficient is approximately 55,000 (440 mμ/M/l./cm).

Consequently, standard solutions of bilirubin in chloroform should be prepared by boiling under reflux. Alkaline standards are stabilized by adding a few mM EDTA per litre. The standard solutions should be kept in the dark. Concentrated solutions are more stable than diluted samples[5] and when human serum is added solutions of bilirubin are stable for many hours[5,6].

Influence of the Injection of a Sucrose Solution on the Properties of Rat-liver Lysosomes

In work recorded here, rats were injected intraperitoneally with 8 ml. of a 50 per cent sucrose solution. They were killed 2 h after the injection. Some of the properties of the hepatic lysosomes were found to be deeply affected by the treatment, namely: (1) their density was reduced, as shown by a shift towards the regions of low density in the distribution curves of their hydrolases, following density equilibration in a glycogen gradient (Fig. 1); (2) their size was increased, as suggested by a fall of the sedimentation boundaries of their enzymes in the centrifuge tube, after incomplete sedimentation in a stabilizing gradient of aqueous sucrose (Fig. 2). On the other hand, the distribution of proteins, used as marker for mitochondria[1] and of particle-bound catalase, remained practically unaltered.

The observed changes may be explained by supposing that some of the injected sucrose is stored up in the hepatic lysosomes along with water required for their tonicity. After an injection of sucrose labelled with carbon-14, some of the sugar was found indeed to be taken up by the liver; using the differential centrifugation technique, according to de Duve *et al.*[2], we noticed that a significant portion of the radioactive material had sedimented with the mitochondrial fraction. Further analysis of this fraction by isopycnic centrifugation in a glycogen gradient made it clear that the distribution patterns of radioactivity and acid hydrolases were the same (Fig. 3). It appears very likely, therefore, that sucrose was indeed collected in the lysosomes.

If the rats are killed more than 2 h after the injection, the percentage of acid hydrolases present under unsedimentable form increases progressively in liver homogenates. This suggests that the filling of lysosomes by aqueous sucrose is going on for hours after the injection. By administering sucrose labelled with carbon-14, we were able to detect indeed an increase in the liver radioactivity up to 24 h after the injection. Becoming larger and larger, the lysosomes become more sensitive, too, to the homogenizing procedure.

The related changes in the properties of lysosomes are reversible. A gradual return to normal was observed during the days which followed the treatment.

These striking modifications of the physico-chemical properties of liver lysosomes are likely to be related to those observed after injection of 'Triton *WR*1339' to the rat[3,4]; like this substance, sucrose stored up in the lysosomes is probably also not affected by the lysosomal enzymes—among them no invertase has been described—so that accumulation can easily be observed; moreover, the small molecular weight of sugar greatly enhances the osmotic content of the granules and would explain their rapid swelling *in vivo* after an injection.

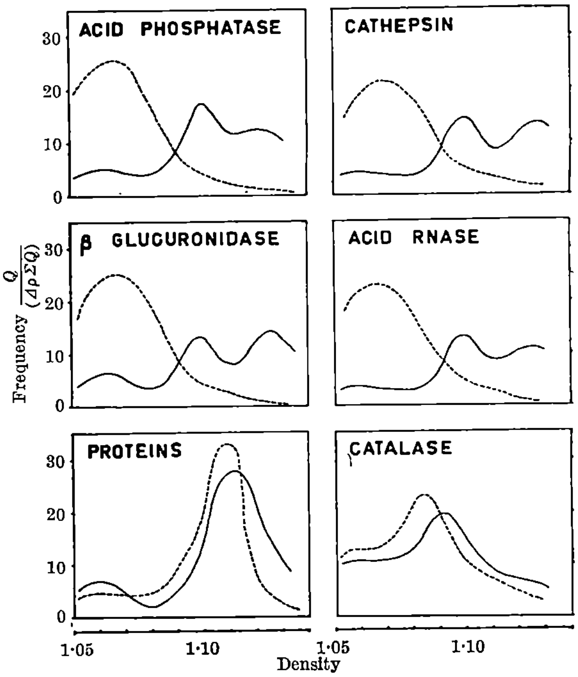

Fig. 1. Distribution of reference enzymes and proteins after centrifugation (for 2·5 h at 39,000 r.p.m. in head *SW*39 of the Spinco model *L-HV* preparative ultracentrifuge) of a mitochondrial fraction of rat liver, through a glycogen gradient extending from 0 to 20 per cent (w/w) with as solvent 0·264 molal sucrose in water. This experiment was performed according to a method similar to that followed by Beaufay *et al.* (ref. 6). Enzyme determinations were made according to the techniques of de Duve *et al.* (ref. 2) and Beaufay *et al.* (ref. 1) for the hydrolases and of Baudhuin *et al.* (ref. 7) for catalase. Proteins were measured by the method of Lowry *et al.* (ref. 8). For the drawing of the curves, the average frequency of the components was calculated for each fraction: $\frac{Q}{\Delta\rho\Sigma Q}$, where Q represents the activity found in the fraction, ΣQ the total recovered activity and $\Delta\rho$ the increment of density from the top to the bottom of the fraction; these values were plotted against density in histogram form and the smoothest possible continuous curve was fitted to this histogram. For calculation details see Beaufay *et al.* (ref. 6). ——, preparation from a control animal; – – –, preparation from an animal killed 2 h after the injection of sucrose

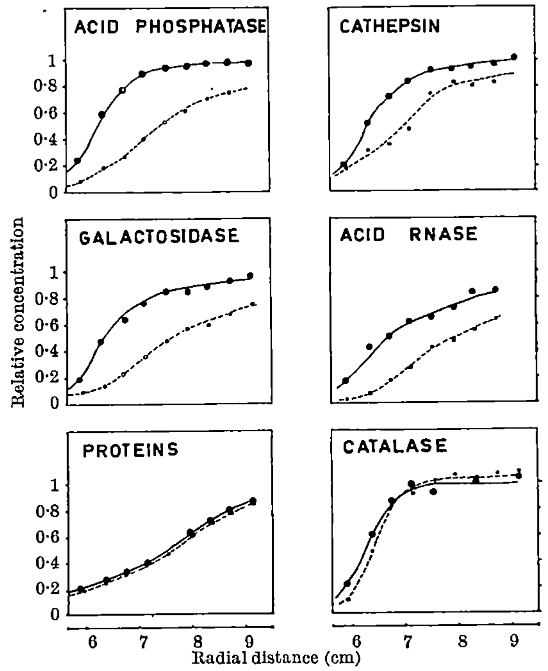

Fig. 2. Sedimentation boundaries of particle-bound enzymes and proteins after centrifugation (for 8 min at 6,000 r.p.m. in head *SW*39 of the Spinco model *L-HV* preparative ultracentrifuge) of a mitochondrial fraction of rat liver, through a linear gradient of 0·25–0·5 M sucrose in water. The experimental technique was similar to the method of Beaufay *et al.* (ref. 1). ——, preparation from a control animal; – – –, preparation from an animal killed 2 h after the injection of sucrose. The relative concentration (ordinate) is the ratio of the observed activity to that which had been found if the enzyme had been homogeneously distributed throughout the whole gradient

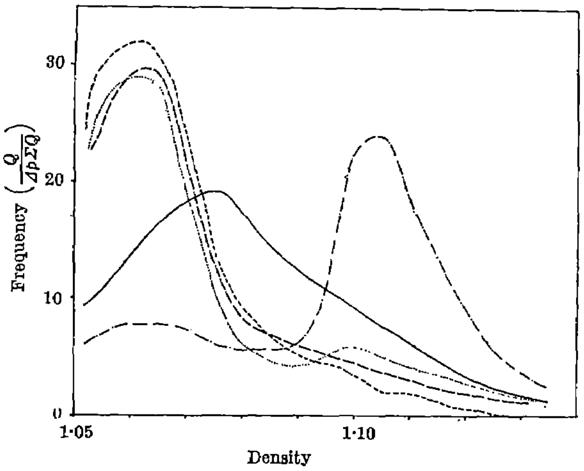

Fig. 3. Distribution of reference enzymes, proteins and radioactivity. Experimental conditions were as in Fig. 1. The mitochondrial preparation comes from a rat injected with 4 g of sucrose dissolved in 8 ml. of distilled water to which was added 20 μc. of sucrose labelled with carbon-14, and killed 2 h after the injection. Radioactivity was measured in a liquid scintillation system using an Ekco scintillator. ------, acid phosphatase; ———, acid ribonuclease; . . . ., radioactivity; –·–·–, proteins; ——, catalase

Further, taken together with the morphological observations of Brewer and Heath[5], our observations on the consequences of a hypertonic sucrose injection in the rat strongly support the hypothesis that vacuolation of the liver cell, produced by this treatment, is initiated by an accumulation of sucrose in the lysosomes.

Effect of Glucose on Insulin Secretion *in vitro* by Rabbit Pancreas pre-incubated with β-Hydroxybutyrate

WE have shown[1] that β-hydroxybutyrate does not induce secretion of insulin *in vitro* as does glucose or citrate. Newsholme, Randle and Manchester[2] have observed a diminution of uptake of glucose (perfused heart) in the presence of β-hydroxybutyrate, acetoacetate and octonoate. They conclude that these substrates inhibit uptake of glucose by inhibiting the intracellular phosphorylation of glucose by hexokinase and the phosphofructokinase reaction. According to Passonneau and Lowry[3] phosphofructokinase is responsive to the balance between ~P expenditure and ~P formation. In view of those results we decided to ascertain the effect of glucose on insulin secretion *in vitro* by rabbit pancreas pre-treated with β-hydroxybutyrate.

A piece of rabbit pancreas weighing 250 mg was incubated in Krebs–Henseleit buffer containing β-hydroxybutyrate 1×10^{-12} M plus glucose 0·6 mg/ml. and another piece of the same weight (± 1 mg) was incubated in the same buffer containing glucose 0·6 mg/ml. for 30 min at 37° C. After washing, the pieces of pancreas were incubated for 15 min in buffer containing 3 mg/ml. glucose. Extraction of insulin from the buffer was performed according to the method of Grodsky and Tarver and estimated by the technique of epididymal fat tissue[4]. The effect of insulin was expressed as uptake of glucose and the statistical analysis of the results was performed using the paired observations method[5].

Table 1. EFFECT OF GLUCOSE (3 MG/ML.) ON INSULIN SECRETION *in vitro* BY RABBIT PANCREAS PRE-INCUBATED WITH β-HYDROXYBUTYRATE (1×10^{-3} M)

Metabolites	Mean glucose uptake (mg/100 mg tissue/4 h)
β-Hydroxybutyrate + glucose (25)	0·352
Glucose (25)	0·517
	± 0·022* $P = 0·01$

* *S.E.M*, the numbers in brackets give the number of experiments.

As can be seen from Table 1, the insulin extracted from the incubation buffer, in which was a piece of pancreas pre-incubated with β-hydroxybutyrate, is significantly less than the control. The effect of glucose as stimulus for insulin secretion *in vitro* seems to be reduced by pre-treatment with this ketone body.

We thank Dr. S. Ochoa for his advice. This work was supported in part by a grant from Eli Lilly Co.

Co-precipitating Properties of 3 *S* Fragments derived from Horse Antitoxins

NISONOFF *et al.*[1,2] showed that precipitating fragments of rabbit antibody obtained by peptic digestion (5 *S* fragments) could be transformed by reductive cleavage into non-precipitating univalent 3 *S* fragments. These results have been taken into account for the new scheme developed by Porter[3] for rabbit γ-globulin structure.

We prepared 5 *S* fragments by peptic digestion[4–6] of specific precipitate (diphtheria toxin + β-2-type horse antitoxin) using 0·08 μg of crystallized pepsin (pH = 2·8; 0·066 M phosphate buffer, 30 min; 20° C). After neutralization and equilibration with 0·02 phosphate buffer pH = 7·8 containing 0·011 M sodium chloride, the soluble fraction is passed through a DEAE-cellulose column. The first part of the non-adsorbed fraction is collected: it is 70–90 per cent precipitable by antigen (diphtheria toxin 3. 100 Lf units*/mg nitrogen) and has a sedimentation constant of about 5 *S*. It will be abbreviated here as *P* (precipitating 5 *S* fragment). Reduction of *P* is not so easy as the reduction of rabbit 5 *S* fragment[1]. The reduction is performed with 0·100 β-mercaptoethanol for 18 h at 20° C and pH = 7·5. After alkylation (with 0·125 M monoiodacetamide) and dialysis, we obtain a fragment having a sedimentation constant equal to 3·0 *S* (value extrapolated to zero concentration of protein). It can be kept at − 15° C without alteration: the product does not aggregate or precipitate spontaneously.

The neutralizing activity is retained, being equal to 80–90 per cent of the activity of *P*, without change of dilution ratio as expressed in Cinader's notation[6]. The

* Flocculation units.

3 S fragment will be designated as i (inhibitory 3 S fragment); i inhibits the passive hæmagglutination test of antigen-coated erythrocytes at a relatively low concentration (0·01 I.U./ml.). We obtained fresh results concerning the inhibitory action of 3 S fragment 'i' on the precipitation reaction. (By itself 'i' does not give any precipitation with antigen.) We observed that the behaviour of the 'i' fragment depends on the P/i ratio. 'i' fragments have been labelled with iodine-131 (ref. 7) for these experiments (i^*).

Mixtures containing different proportions of P and i^* have been used. Toxin is first mixed with i^*, then P is added. The proportion of antigen (toxin) is equal to the sum of antibody ($P+i^*$) used. This point is an important one (see following).

It can be seen (Fig. 1) that for P/i^* lower than or equal to 0·50, one observes a total inhibition of the precipitation. This value of P/i^* can be called 'critical P/i value'. (This result is in accordance with classical observations in this field. The 'critical P/i value' found by Porter[8] for rabbit antipolysaccharide antibodies is much lower: 0·04 (calculated from Fig. 4, ref. 8).) For a ratio P/i^* between 0·5 and 1·0, there is only a partial inhibition: the total amount of precipitated nitrogen is lower than that corresponding to the precipitating antibody (P) alone present in the mixture. Nevertheless, a part of the specific precipitate contains the 'inhibitory' monovalent fragment i^*, as shown by precipitate's radioactivity. For a ratio P/i^* between 1 and 2 there is no apparent inhibition: the total amount of precipitated nitrogen is higher than the amount corresponding to the precipitating antibody (P), but the i^* fragment is only partially co-precipitated. For a sufficiently high value of P/i^* (more than 4) all the monovalent 3 S i^* fragment is co-precipitated with P. The influence of the proportion of antigen used is more apparent when a complete precipitation curve is plotted for a mixture corresponding to a P/i^* ratio, equal to 5. We have by these means observed that the presence of the monovalent 3 S fragment in the mixture has several effects. (1) It enhances the length of the inhibition zone in antibody excess (this inhibition zone is one of the characteristic features of horse's β-2-antitoxin). (2) If the amount of antigen added is lower than the amount equivalent to $P+i^*$, the co-precipitation of i^* is incomplete. (3) If the amount of antigen is sufficiently large, the whole 3 S fragment is co-precipitated. It is possible to calculate, from the curve, the minimal amount of antigen which may be used for this purpose and which can be said to be 'equivalent to $P + i^*$'.

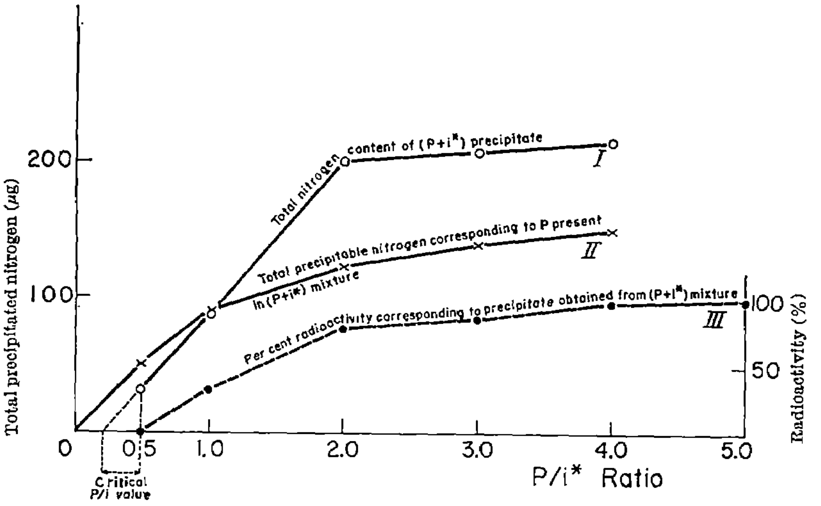

Fig. 1. Influence of the P/i^* ratio with $T=P+i^*$. Curve I corresponds to the total nitrogen found in the precipitate obtained by adding a constant amount of antigen (100 *Lf units of diphtheria toxin) to a constant amount of* $P+i^*$ (100 I.U. of antitoxin), containing variable proportions of P and i^*. Curve II is the total nitrogen which could be obtained by adding to P the equivalent amount of antigen (T) in the absence of i^*. Curve III corresponds to the per cent of radioactivity (i^*) recovered in the specific precipitate. T, pure diphtheria toxin. P, purified 5 S antibody fragment. i^*, ^{131}I-labelled 3 S fragment

These results show that it will now be possible to devise for any system a quantitative test for measuring non-precipitating fragments of antibody. This test can be probably applied to the quantitative determination of residual antibody activity of A or B chains, provided they are obtained in an aqueous soluble form.

Stimulation of Steroid C-11β Hydroxylase Activity in Adrenal Homogenates by Cyclic 3′,5′-Adenosine Monophosphate

Steroid biosynthesis in the mammalian adrenal cortex is dependent on the activity of a number of complex enzyme systems, including several hydroxylases which require NADPH as cofactor[1]. NADPH is continuously generated from NADP within the adrenal cortex by the action of several dehydrogenases acting on appropriate substrates[2]. Of the latter, glucose-6-phosphate appears to be the most important[3]. Haynes, Koritz and Péron[4] demonstrated that adenosine-3′,5′-monophosphate (cyclic 3′,5′-AMP) enhanced the production of corticosterone from endogenous precursors by surviving rat adrenal sections. Since cyclic 3′,5′-AMP also stimulated phosphorylase activity in adrenal slices, the effect of the nucleotide on corticosteroidogenesis was apparently related to increased provision of glucose-6-phosphate[5]. Of added significance was the observation by Haynes[5,6] that ACTH resulted in the accumulation in adrenal slices of cyclic 3′,5′-AMP, which presumably was responsible for the resulting stimulation of corticosteroidogenesis. Attempts to demonstrate a stimulatory effect of cyclic 3′,5′-AMP on corticosteroidogenesis from endogenous substrates in adrenal homogenates have hitherto been unsuccessful[4,7]. In the investigations recorded here, addition of this nucleotide to rat adrenal homogenates markedly stimulated C-11β hydroxylation of added progesterone and 11-deoxycorticosterone, but appeared to have no effect on C-21 hydroxylation of progesterone.

Adrenal glands were obtained under light 'Nembutal' (sodium pentobarbital) anæsthesia from young male rats (120–150 g) of an inbred Sprague–Dawley strain. The glands were dissected free of fat and connective tissue, cut into eighths, and subjected to a preliminary incubation for 1 h in a medium composed of 109 parts 0·154 M sodium chloride and 21 parts 0·154 M sodium bicarbonate[7]. Preformed steroid hormones were removed by this procedure. The adrenals were then blotted, weighed and homogenized for 0·5 min in cold 0·154 M potassium chloride. The homogenate was diluted to a concentration of 75 mg wet weight of tissue per ml. The final incubation mixture contained 0·4 ml. of homogenate (30 mg adrenal tissue), 40 μmoles $NaHCO_3$, 7 μmoles Na glucose-6-P, and 2·1 μmoles NaNADP, made up to 2 ml. with 0·154 M KCl. The presence of varying amounts of (4-^{14}C)-progesterone or (4-^{14}C)-11-deoxycorticosterone, cyclic 3′,5′-AMP, and other additives is indicated in the results. All incubations were carried out in a Dubnoff metabolic incubator at 37·5° under an atmosphere of 95 per cent oxygen–5 per cent carbon dioxide.

After incubation, the media were each extracted three times with 6 ml. of methylene chloride. Total radioactivity recovered from the incubation mixture was determined on an aliquot of the extract by a scintillation counting procedure[8]. Purification of the steroidal products was accomplished by partition between 70 per cent ethanol and petroleum ether. Finally, the steroid residue was dissolved in ethyl acetate/methanol (1 : 1) for analysis by thin-layer chromatography. The chromatographic system most commonly used was system *L* of Lisboa[9], utilizing chloroform/ethanol (19 : 1). Plates, 2 in. × 8 in., were coated with a 250μ layer of 'Silica Gel *G*' containing 2·5 per cent zinc silicate to provide a fluorescent background against which the separated steroids could be visualized more readily by their absorption of ultra-violet light[10]. The chromatogram was allowed to develop at 25° until the solvent front had ascended 15 cm. Appropriate standards were run alongside each incubation sample. The plate was dried, photographed in ultra-violet light, then analysed for radioactivity on the Packard chromatogram scanner, model 7200. Recovery of radioactive steroids carried through the extraction procedure averaged 80 per cent[11]. Additional methods used for the separation and identification of the steroidal incubation products will be described in detail[11].

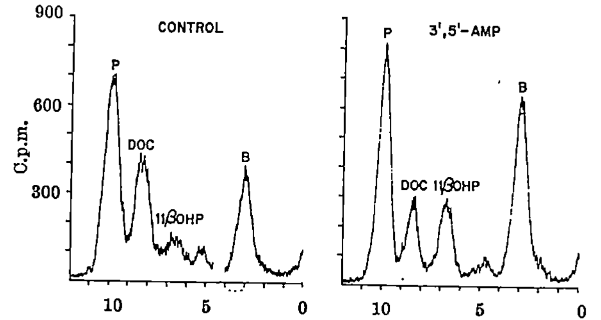

Fig. 1. Radioactivity scanning patterns of thin-layer chromatograms, showing corticosteroids formed from (4-^{14}C)-progesterone in rat adrenal homogenates. The incubation medium (2 ml.) contained $16{\cdot}2 \times 10^{-2}$ μmoles progesterone (0·05 μc.) in 0·0125 ml. of 95 per cent ethanol; 8 μmoles of cyclic 3′,5′-AMP were added where indicated. Chromatographic origin is represented by 0 on abscissa.
P, progesterone; DOC, 11-deoxycorticosterone; 11βOHP, 11β-hydroxyprogesterone; B, corticosterone

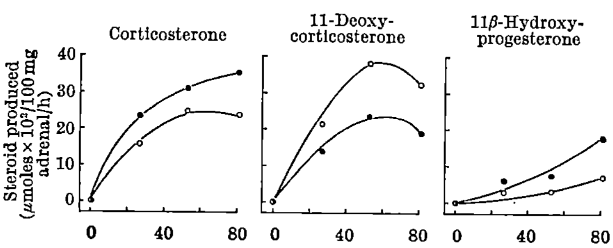

Fig. 2. Influence of cyclic 3′,5′-AMP on conversion of (4-^{14}C)-progesterone to corticosteroids by rat adrenal homogenates. In each case, 0·05 μc. of steroid was present in 0·0125 ml. 95 per cent ethanol per 2 ml. of medium. Results are based on percentage recovery of added radioactivity in each metabolite after incubation for 15 min. Open circles, controls; solid circles, 8 μmoles of cyclic 3′,5′-AMP added

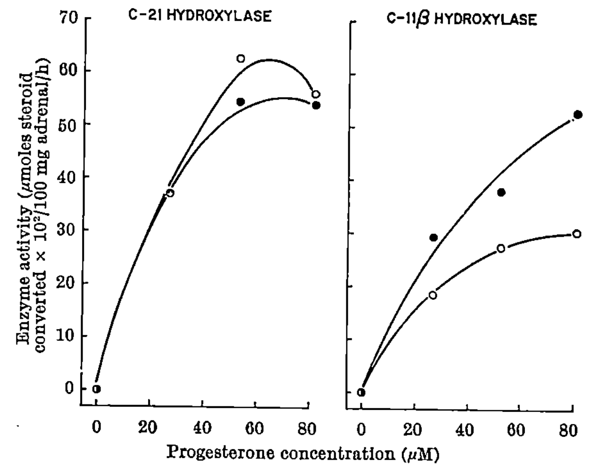

Fig. 3. Selective influence of cyclic 3′,5′-AMP on steroid hydroxylations in rat adrenal homogenates. See legend to Fig. 2 and text for explanations

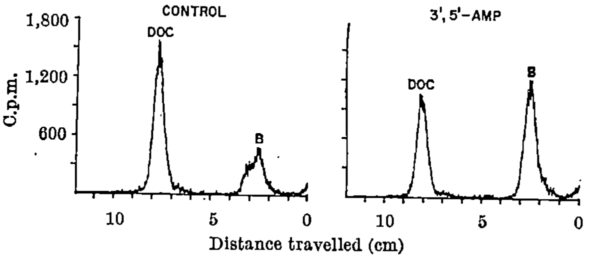

Fig. 4. Radioactivity scanning patterns of thin-layer chromatograms, showing conversion of (4-^{14}C)-11-deoxycorticosterone to corticosterone in rat adrenal homogenates. The incubation medium (2 ml.) contained $21{\cdot}0 \times 10^{-3}$ μmoles 11-deoxycorticosterone (0·05 μc.) in 0·0125 ml. of 95 per cent ethanol; 8 μmoles of cyclic 3′,5′-AMP were added where indicated. See legend to Fig. 1 for additional explanations

In incubation periods of 15-min duration the major products formed from (4-^{14}C)-progesterone were 11-deoxycorticosterone and corticosterone (Fig. 1, control). In some instances, measurable quantities of 11β-hydroxyprogesterone were also formed. The influence of varied amounts of added progesterone on the production of these corticosteroids is shown in Fig. 2 (open circles). Although the conversion to corticosterone and 11-deoxycorticosterone reached a maximum at 50 μM progesterone, the formation of 11β-hydroxyprogesterone tended to increase with additional substrate. The transformations involved may be represented by the following scheme:

$$\begin{tikzcd}
\text{progesterone} \arrow[r, "\text{C-21 hydroxylase}"] \arrow[d, "\text{C-11}\beta\text{ hydroxylase}"'] & \text{11-deoxycorticosterone} \arrow[d, "\text{C-11}\beta\text{ hydroxylase}"] \\
\text{11}\beta\text{-hydroxyprogesterone} & \text{corticosterone}
\end{tikzcd}$$

The activity of the C-21 hydroxylase enzyme system may be estimated from the combined rates of formation of 11-deoxycorticosterone and corticosterone. Similarly, overall C-11β hydroxylase activity can be measured from the combined rates of formation of 11β-hydroxyprogesterone and corticosterone. In incubation studies of longer duration than 15 min, additional products were formed, complicating estimation of enzymatic activities.

Cyclic 3′,5′-AMP had a striking effect on the pathway of progesterone utilization (Fig. 1). Corticosterone formation was markedly enhanced at the expense of 11-deoxycorticosterone; concomitantly, the production of 11β-hydroxyprogesterone was doubled (Fig. 2, solid circles). The net effect of 3′,5′-AMP was a striking and selective stimulation of overall steroid C-11β hydroxylase activity (Fig. 3). This action of the cyclic nucleotide was accentuated at the highest concentration of progesterone. No effect on endogenous steroid utilization was noted[4,7]. Under the conditions of the experiments described here, steroid C-21 hydroxylase activity appeared to be maximal at about 50 μM progesterone (Fig. 3). However, the lack of responsiveness of this enzyme system to cyclic 3′,5′-AMP was not due to saturation with substrate. Thus, even at the highest substrate-level C-21 hydroxylase activity was stimulated about 35 per cent on addition of 0·1 ml. fresh rat serum to the incubation medium. Homologous serum has previously been shown to activate C-21 hydroxylation of added progesterone in adrenal homogenates[11] and microsomes[12]. In separate experiments, conversion of (4-^{14}C)-11-deoxycorticosterone to corticosterone was enhanced by cyclic 3′,5′-AMP (Fig. 4); 5′-AMP, the degradation product of 3′,5′-AMP, was only half as effective. ATP (2 mM) plus Mg^{++} (3 mM) also stimulated C-11β steroid hydroxylations in the presence of either substrate. This finding raised the possibility that adenyl cyclase was active in adrenal homogenates.

The selective stimulation of C-11β hydroxylations in adrenal homogenates by cyclic 3′,5′-AMP may have been brought about via enhancement of glucose-6-phosphate formation from glycogen and a resultant increase in NADPH generation. Although stimulation of NADPH generation in the adrenal cortex would be expected to accentuate all steroid hydroxylations, recent investigations from this laboratory[11] have shown that concentrations of NADPH-generating system in excess of the requirement for maximal production of corticosterone from progesterone selectively enhanced C-11β hydroxylation of this substrate. The mechanism of this phenomenon is not clear but may be related to a differential requirement for NADPH by mitochondrial C-11β hydroxylase and microsomal C-21 hydroxylase enzyme systems or to some functional association between the NADPH-generating system and adrenal mitochondria[11].

These observations may help in the elucidation of the mechanism of action of ACTH. A selective action of ACTH on C-11β hydroxylations in the adrenal cortex has been reported by Grant[13]. The investigations recorded here indicate that this selective effect of ACTH on steroid hydroxylations may be associated with rapid generation of NADPH in response to elevated levels of cyclic 3′,5′-AMP.

Relationship between Pyrophosphate Content and Oxytetracycline Labelling of Bone Salt

HEATING of bone to 325° C has been shown to induce the formation of pyrophosphate[1-3]. The quantity of pyrophosphate so formed is greater in the epiphysis than in the diaphysis and greater in the younger than in the older animal, and is therefore presumably greater in newly laid down than in older bone salt[1]. The question to be investigated is whether pyrophosphate-yielding mineral of new bone has specific chemical characteristics. There is much evidence which suggests that the tetracyclines are deposited in high concentrations in newly formed bone salt[4]. This communication demonstrates that the tetracycline labels the form of the bone salt that yields pyrophosphate in large amounts after heating.

Two New Zealand rabbits were injected with 25 mg of oxytetracycline intravenously and killed 24 h later. The long bones of the hind quarters were excised and ground in a hand coffee mill. The resulting small particles were separated into two groups by means of ultra-violet light and a dissecting microscope. The particles that fluoresced brightly were picked out with the forceps and placed in one crucible while those that had no visible fluorescence were collected in another. Each crucible was heated to 325° C for 1 h in a muffle oven. The ortho- and pyro-phosphates obtained from these samples were separated by the method of François[5]. The resin used was 'Bio-Rad *AG* 1 × 8, 200–400 mesh'. Pyrophosphate was hydrolysed by heating for 30 min in 1 N hydrochloric acid at 100° C, and the orthophosphate was determined by the Fiske–Subbarow method[6]. The results, summarized in Table 1, clearly demonstrate that the fluorescent particles contain the mineral with the greatest potential for forming pyrophosphate. This corroborates the observation that both the tetracycline reactive and pyrophosphate-yielding minerals are found in less than 1 per cent of the bone salt that is the exchangeable, reactive, labile or metabolic fraction. The exact composition and structure of this fraction are not known, but the following are possibilities that have been considered in the literature: monetite, brushite, octacalcium phosphate, hydrated tricalcium phosphate, calcium-deficient apatite. New observations with new methods may be made using the foregoing method of labelling and separation of new mineral.

Table 1. PYROPHOSPHATE CONTENT OF BONE WHICH DOES AND WHICH DOES NOT BIND WITH OXYTETRACYCLINE

Sample	Rabbit (approximate age)	$\frac{\text{Pyrophosphate} \times 100}{\text{ortho- + pyro-phosphate}}$
Oxytetracycline-labelled bone	1–2 yr.	10·3
	6 mo.	15·8
Non-labelled bone	1–2 yr.	3·6
	6 mo.	5·0

Effect of Nicotinic Acid on Sterol Biosynthesis in *Saccharomyces cerevisiae*

In 1955, Altschul *et al.* reported[1] that large doses of nicotinic acid, but not of its amide, decreased serum cholesterol-levels in man and rabbit. This finding has been confirmed by many workers[2]. Despite several investigations of mechanisms, however, the locus of the nicotinic acid effect remains unknown[3,4]. We wish to report an effect of high concentrations of nicotinic acid on sterol biosynthesis in yeast. This effect may account for the hypocholesteremic action of nicotinic acid.

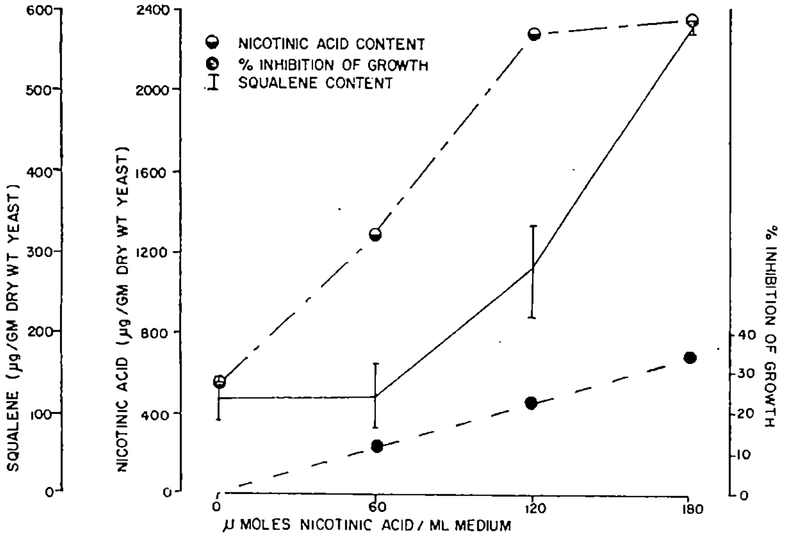

Fig. 1

Saccharomyces cerevisiae UT-139, a prolific producer of sterols[5], was grown at 25° C, with gentle stirring, in Fernback flasks containing 500 ml. medium. The medium was prepared according to Atkin[6], with the addition of 0·068γ biotin/ml. The initial *p*H of all media was 5·5–5·6. Nicotinic acid and mevalonic acid-2-^{14}C were added as in Fig. 1 and Table 1. An elevated or reduced oxygen tension was obtained by bubbling air or nitrogen into the medium and carbon dioxide was collected in 2 N sodium hydroxide.

Cells were collected at given times by centrifugation and washed three times with cold 0·85 per cent saline. Dry weight was determined on aliquots of cells dried at 85° C. Lipids were extracted from the wet cells either by repeated grinding with sea sand and Folch reagent[7] or by saponification[8]. Squalene and sterols in the non-saponifiable fraction were quantitatively determined by gas liquid chromatography. Cholestane or allopregnane-3,20 dione was the internal standard. The column, 6 ft. by 0·25 in. internal diameter silanized glass U tube, contained 2 per cent '*SE*-30' coated on 80–100 mesh 'Diaport *S*' and was housed in an F. and M. model 609 flame ionization instrument. For determination of specific activities, squalene and sterols were isolated by silicic acid thin layer chromatography, using hexane/ether/acetic acid, 80 : 20 : 1·5, as the developing solvent. The radioactivity taken up by whole yeast cells was determined in a flow-gas counter and corrected to infinite thinness. Lipid fractions and $^{14}CO_2$ in hyamine[9] were counted in a Packard liquid scintillation spectrometer. Nicotinic acid was determined by microbial assay[10].

It was observed (Fig. 1) that the squalene content of yeast cells increased almost linearly as the nicotinic acid concentration in the medium was increased. This effect was preceded by elevation of nicotinic acid levels in the cells and associated with growth inhibition. In these and other experiments (Table 1), a small depression in total sterol-levels and a marked fall in lanosterol content were noted when nicotinic acid was present in the medium. This suggested that nicotinic acid was inhibiting the conversion of squalene to sterols at the squalene oxidocyclase step[11].

To test this hypothesis further, the incorporation of acetate-1-^{14}C and mevalonic acid-2-^{14}C (MVA) into non-saponifiable lipid was studied. In the MVA experiment, cells were grown under both elevated and reduced oxygen tensions. The latter condition was used because it was thought that nicotinic acid might magnify the inhibitory effect of anaerobiosis on squalene cyclization. In the presence of nicotinic acid there was a marked fall both in total radioactivity taken up by cells and in the specific activity of the non-saponifiable lipid with little change in mass (Table 1). This result appears to be due to an effect of nicotinic acid on the uptake of mevalonate from the medium since the specific activity of whole cells, the radioactivity recovered in $^{14}CO_2$ per mg cell, and the fall in specific activity of non-saponifiable lipid were of the same order. By similar reasoning, it was concluded that reduced oxygen tensions in the absence of nicotinic acid stimulated MVA uptake. This novel blockade of mevalonate uptake by nicotinic acid seems to be independent of the effect on sterol biosynthesis. The latter, therefore, was evaluated by comparing the specific activities of given non-saponifiable lipids after correction for the penetration effect.

The results (Table 1) clearly demonstrated that in the presence of nicotinic acid and MVA, under both oxygen tensions, squalene mass and total radioactivity increased, while sterol mass and total radioactivity decreased. Similar distribution of radioactivity in lipids was noted with acetate-1-^{14}C as substrate, although with this substrate no effect of nicotinic acid on uptake by cells

Table 1. Effect of Nicotinic Acid (180 μmoles/ml. Medium) on the Uptake and Incorporation of Mevalonic Acid 2-^{14}C into Yeast Cells

Exp. No.	Growth conditions		Penetration effect Radioactivity in fractions				Biosynthetic effect Mass and radioactivity in lipids				
	Nicotinic acid	Oxygen tension	*A* Yeast cell* (d.p.m./g)	*B* $^{14}CO_2$ (d.p.m./g)	Non-saponifiable lipid		Squalene		Sterol†		Lanosterol mg/g
					Spec. act. (d.p.m./mg)	% total act.	mg/g	d.p.m./g	mg/g	d.p.m./g	
1	–	Elevated	136,000	718	2,731	39·0	0·126	459	19·3	70,368	3·6
2	+	Elevated	57,000	308	647	19·3	1·285	4,925‡	16·3	11,977‡	2·3
3	–	Reduced	821,250	1,666	24,963	41·7	2·059	162,157	11·6	246,054	4·0
4	+	Reduced	51,139	80	904	47·1	6·565	218,231‡	5·6	68,298‡	2·7

Mevalonate was present as the DBEB salt; 10 μc./500 ml. medium. Yeast cells were gathered during the log phase (controls: 15 h; nicotinic acid inhibited: 40–50 h, depending on oxygen tension).

* The efficiency factor (20 per cent) was based on the value given by 5 mg of $Ba^{14}CO_3$ ($3{\cdot}01 \times 10^{-1}$ μc./mM).

† Sterols measured include zymosterol, ergosterol, two unidentified sterols and lanosterol.

‡ Specific activity is corrected for normal penetration of isotope by the factor: $(A+B)_{\text{control}}/(A+B)_{\text{nicotinic acid}}$.

was observed. These results strengthen the view that nicotinic acid inhibits the cyclization of squalene.

The general mechanism of sterol biosynthesis in yeasts is similar to that of cholesterol biosynthesis in animals[12]. From rat liver slice experiments, Gamble and Wright concluded[13] that nicotinic acid inhibits cholesterol biosynthesis prior to MVA. However, these experiments have been criticized[4]. Since divergence of pathways in sterol biosynthesis in yeast as compared to animal tissues occurs after the formation of lanosterol[12], it is possible that nicotinic acid acts at the squalene cyclization stage rather than prior to MVA in animals. This possibility is under continuing investigation.

We thank Dr. J. O. Mundt, Department of Bacteriology, University of Tennessee, Knoxville, Tenn., for supplying the culture of *S. cerevisiae UT*-139, and Dr. O. N. Brevik, Fleischmann Labs., Stamford, Conn., for an authentic sample of zymosterol. This work was supported in part by grants from the National Institutes of Health of the U.S. Public Health Service (1501-*FR* 05151 and 5 *TI GM* 564 respectively).

Metabolism of Phenoxyacetic Acid by *Aspergillus niger* van Tiegh

A RECENT communication[1] reported the isolation of *o*-hydroxyphenoxyacetic acid as the main acidic product from the metabolism of phenoxyacetic acid by *A. niger*, using a replacement culture technique. Since these findings contrasted with our earlier work[2] in which both *o*- and *p*-hydroxyphenoxyacetic acids had been isolated, it was thought advisable to re-investigate the problem.

It has now been shown using both paper and thin-layer chromatography that while ortho-hydroxylation is predominant, all three hydroxyphenoxyacetic acids are in fact produced. While the *m*- and *p*-isomers have very similar R_F values in the three solvents used, their presence is clearly indicated by the characteristic colours of the diazo-coupled spots (*m*-isomer, bright yellow; *p*-isomer, salmon-pink). Exposure of the chromatogram to ammonia vapour changed the colour of the *m*-spot to magenta and that of the *p*-spot to bright blue. Furthermore, the relative positions of the spots are reversed in the two solvent systems used in the paper chromatographic examination.

Cultures of *A. niger* (Mulder strain, C.M.I. 31283) were grown in penicillin flasks and after 3 days the medium was replaced by a solution of phenoxyacetic acid (10^{-3} M) in aqueous disodium hydrogen phosphate (10^{-2} M). After 24 h at 26°, the substrate was poured off and concentrated in a cyclone evaporator, and the acidified concentrate continuously extracted with ether.

In a typical experiment, from 31 l. of fungal substrate initially containing 4·7 g phenoxyacetic acid, 3 g of sodium bicarbonate-soluble material was isolated. Separation was achieved by partition chromatography using silica gel as the supporting medium for the stationary aqueous phase which was buffered to *p*H 8, the mobile phase being *n*-butanol–chloroform (successively 60 : 40, 70 : 30, 80 : 20). After elution of unidentified material (0·9 g) and unchanged phenoxyacetic acid (1·42 g), the monohydroxyphenoxyacetic acids followed in the order *o*-(0·4 g), *m*-(0·02 g) and *p*-(0·1 g), details of their identification being given in Table 1.

Table 1. HYDROXYPHENOXYACETIC ACIDS

Solvent *A*: butanol/ethanol/3 N ammonia (4 : 1 : 5).
Solvent *B*: propanol/0·880 ammonia (7 : 3).

The difference between these findings and our earlier report[2] may reflect an improved separation technique or it may be due to a strain difference in *A. niger*. The culture used in the earlier work was Mulder strain, which had been in use at Long Ashton for some years previously; current practice is to renew the inoculum at frequent intervals from the Commonwealth Mycological Institute. The general pattern of hydroxylation appears to be relatively non-specific—resembling the metabolism of 2- and 4-chlorophenoxyacetic acids[3], but contrasting with results obtained in the metabolism of 2-naphthyloxyacetic acid[4] and with recent results obtained with 2,4-dichlorophenoxyacetic acid[5].

The metabolism of phenoxyacetic acid by a wild-strain of *A. niger* (kindly supplied by Dr. S. M. Bocks) has also been investigated. Thin-layer (propanol/0·880 ammonia (7·5 : 2·5) using 'Silica Gel *G*') and paper chromatographic examinations of acidic material obtained from four separate experiments using the replacement culture technique clearly reveal the presence of all three hydroxyphenoxyacetic acids, though the *m*- and *p*-isomers are present in a lower proportion than in the case of the Mulder strain.

PHYSIOLOGY

Effect of Intraventricularly Injected Anti-cerebral Antibodies on the Histamine-like Substance and Potassium Content of Various Regions of the Brain of the Cat

IN an attempt to investigate the possible differential reactivity of various cerebral structures when exposed to the action of different brain region anti-sera, it has been shown that the injection of heterologous anti-caudate nucleus antibody into the lateral cerebral ventricle of the cat was followed by pronounced electrographic abnormalities, confined mainly to the caudate nucleus. Since the electrical activity of other, simultaneously investigated brain regions was not essentially modified, the alterations observed were interpreted as being strongly suggestive of the possibility that the anti-caudate antibody has an affinity for the homologous nervous tissue[1].

Pursuing this line of investigation and having in mind the well-known fact that, in general, an antigen–antibody reaction is associated with a release of histamine, 5-hydroxytryptamine and other biologically active substances, a series of experiments have been undertaken to test: (1) if a similar phenomenon occurs when the brain is attacked by an intraventricularly injected anti-brain antibody; (2) whether or not the differential reactivity of various brain structures to the action of an antibody produced against the tissue of specific cerebral region, as suggested by previous experiments, could be ascertained using as indicators the variations in the histamine and potassium contents. This communication refers to the effects of intraventricularly injected anti-caudate and anti-hippocampal antibodies on the histamine-like substance and potassium contents of the frontal cortex, caudate nucleus, hippocampus and the cerebrospinal fluid of the cat.

The methods used for the preparation of antigens, immunization and separation of γ-globulins from immuno rabbit sera were the same as those previously described[1,2]. Immune anti-caudate and anti-hippocampal γ-globulins were tested by diffusion in gel and complement fixation reaction in which saline extracts and lipids (ethanol extracted) of caudate and hippocampal tissues respectively were used as antigens. Thus, tested normal rabbit γ-globulins, obtained from the sera prior to immunization, did not show any serological activity.

Experiments were performed on unanæsthetized adult cats carrying the cannula inserted under aseptic conditions (at least five days earlier) into the same, anterior portion of the lateral cerebral ventricle according to the method of Feldberg and Sherwood[3]. Animals were divided into three groups: the first group was injected with the anti-caudate, the second with the anti-hippocampal and the third group of animals with the normal γ-globulin. Three injections of 0·3 ml. containing 40 mg of protein were administered successively with an interinjection interval of 60 min. One hour following the last injection, animals were anæsthetized ('Nembutal', 0·6 ml. of 5 per cent solution/kg), the cerebrospinal fluid obtained by means of sub-occipital puncture and immediately centrifuged at 2,500*g*. Then the animals were killed and tissue samples from the head of caudate nucleus, hippocampus and the frontal cortex were quickly dissected, taking care to obtain the equal amounts of tissue from both hemispheres of the brain.

A histamine-like substance from the brain tissue was extracted according to the method of Barsoum and Gaddum[4] as modified by Kwiatkowski[5], while that from the cerebrospinal fluid and blood was extracted according to Code's method[6]. The extracts were then assayed on the guinea pig ileum suspended in 3 ml. of oxygenated, magnesium-free, Tyrode's solution, containing $1/3 \times 10^{-7}$ of atropine. Contractions induced by brain extracts could be antagonized by adequate doses of antistin. All values for histamine-like substance refer to the base. The tissue for potassium determination was deproteinized and potassium in tissue filtrate, the cerebrospinal fluid and plasma estimated by means of an EEL flame photometer.

*P, 0·01.

The results are presented in Table 1. They show, first of all, that in contradistinction to the normal rabbit γ-globulin, an immune anti-cerebral γ-globulin, when injected into the lateral cerebral ventricle of cat, produces an important increase of histamine-like substance in the brain. Furthermore, they demonstrate an apparently differential reactivity of various cerebral structures to the action of an antibody produced against the tissue of specific brain region. Thus, an intraventricular injection of anti-caudate antibody resulted in a significant increase of histamine-like substance in the tissue of the head of caudate nucleus, associated in some instances with its increase in the cerebrospinal fluid, but not (or at least not in a significant degree) in tissues of other cerebral structures investigated. On the other hand, the increased content of histamine-like substance following intraventricular injection of anti-hippocampal antibody was not evidenced in any other cerebral region investigated, but in the hippocampus itself and in some cases in the cerebrospinal fluid as well. Results were statistically tested using the method of variance analysis. The predominant increase of histamine-like substance in the caudate nucleus and hippocampus following the intraventricular injection of anti-caudate and anti-hippocampal antibodies, respectively, proved to be statistically significant (P = 0·01). Although in some of these experiments the values of histamine-like substance in the cerebrospinal fluid were remarkably high with respect to normal, the differences as expressed by the means were not found to be statistically significant. It should be added that in another series of experiments, in which the histamine content of both caudates and hippocampi was separately estimated, the increase of the amine was usually, but not necessarily, greater on the cannulated side of the brain. Potassium concentrations of investigated cerebral tissues as well as that of the cerebrospinal fluid were not essentially modified.

On the basis of electroencephalographic findings reported in a previous communication[1], the idea has been put forward suggesting the possible regional specificity of some high molecular weight substances present in morphologically and functionally differentiated parts of the central nervous system. Although the results of the present experiments challenge the discussion in many other directions, only the aspects pertaining to problems implied in the aforementioned hypothesis will be briefly commented. Despite the high degree of differentiation, various portions of the grey matter of the central nervous system could still be considered morphologically similar in that they are all composed of neurones, glia cells, unmyelinated and myelinated fibres, blood vessels, elements of the supposedly common ground substance, etc. Therefore, in view of the high specificity of serological reactions, so amply attested by Landsteiner[7], it can be assumed that immune γ-globulins used in our experiments contained a bulk of antibodies against the number of various components present in homogenates of given brain regions, including non-specific ones, common to the brain as a whole. Yet, as could be judged on the basis of variations in contents of histamine-like substance found in the present experiments, anti-caudate and anti-hippocampal γ-globulins were still able to 'recognize' the corresponding nervous structures. It could be inferred from these considerations that the predominant (if not selective) increase in the histamine-like substance content in the part of the brain attacked by the corresponding antibody indicates that in the antigen–antibody reaction are involved primarily those elements (most likely cellular, whatever they might be: neurones, glia or both) which determine the antigenic specificity of the given nervous structure.

Possible Role of a Phospholipid in the Development of the Slow Muscle Contracting Activity of Human Plasma

THE presence of a substance in the *G*.2 fraction of human blood plasma with a slow contracting activity on plain muscle (S.M.C.) was established and the active principle has been isolated from the *G*.2 fraction and designated as *G* acid[1]. It is important to note that the same effect has been obtained from citrated human plasma and is best observed with dialysed plasma, since dialysis eliminates the quick contracting agents[2]. The chemical nature of *G* acid prompted a search for a possible precursor of this lipid-soluble unsaturated fatty acid (3-octadecenoic acid)[1].

Although the *G*.2 fraction stimulates the isolated guinea pig ileum, the γ-globulin and the albumin fractions are much less active on the same muscle preparation. The S.M.C. effect of human plasma and of *G*.2 fraction is reduced to about 50 per cent of the initial effect after the addition of calcium ions to a final concentration of M/40. The serum prepared by recalcification of the plasma is much less active on smooth muscle than the serum obtained after clotting the same plasma with human thrombin.

The formation of a slow muscle-contracting substance by alkaline hydrolysis of lecithin or by the action of phospholipase *A* present in cobra venom on lecithin[3], and the recognition of another variety of phospholipid in human serum identified as lysolecithin[4], suggested the investigation of the effect of human plasma on egg lecithin *in vitro*. The results obtained show that the addition of egg lecithin (0·25 per cent) to plasma causes a marked increase in its S.M.C. activity which is neutralized by the addition of calcium ions to a final concentration of M/40. Lecithin alone is inactive on the isolated ileum of a guinea pig at the same level of dosage. Incubation of the plasma with lecithin at 37° C or raising the *p*H of the plasma to 8 increases the slow contraction of smooth muscle produced by lecithin-plasma. Olive oil, cotton-seed oil and butter fat do not produce similar effects on smooth muscle when emulsified with human plasma and incubated at *p*H 8.

It may be interesting to note that the amount of egg lecithin which doubles the S.M.C. effect of human plasma is about 250 mg per cent of the plasma, a concentration which roughly corresponds to the concentration of the naturally occurring choline-containing phospholipids in human plasma. Parallel results were not obtained after incubation of egg lecithin with 5 per cent solution of human serum albumin in saline.

The S.M.C. effect produced by lecithin added to human plasma is not antagonized by atropine or by antazoline. Similar to the S.M.C. effect of the original plasma, the S.M.C. effect produced by added egg lecithin is not destroyed by an esterase-rich fraction of blood which destroys acetylcholine under the same conditions. The esterase-rich fraction is produced during the purification of human serum albumin by the method of Kekwick and Mackay[5].

Processing of human plasma with kaolin considerably decreases its effect on the isolated ileum of a guinea pig[6,7]. The S.M.C. effect produced by lecithin added to human plasma is completely abolished by the same treatment. The S.M.C. effect of such plasma is indistinguishable from the S.M.C. effect of kaolin-treated plasma without added lecithin.

Brown Adipose Tissue and Thermoregulatory Heat Production in the Rat

THE role of brown adipose tissue in thermoregulatory heat production of the cold-adapted rat was inferred by R. E. Smith from the thermogenic activity of the interscapular fat *in vitro*[1] and the anatomical distribution of brown adipose tissue in the body[2]. The thermogenic role of brown fat has been directly demonstrated in the hibernating hamster by measuring temperatures at various sites in the body[3], and by measuring simultaneously the oxygen consumption of the whole animal, in the new-born rabbit[4,5].

In our experiments, copper-constantan thermocouples were inserted under light urethane anæsthesia (0·8 g/kg body-wt.) into adult rats adapted to room temperature at the following sites: (1) midbrain, 7 mm deep; (2) colon, 10 cm from the anus; (3) interscapular fat; (4) muscle,

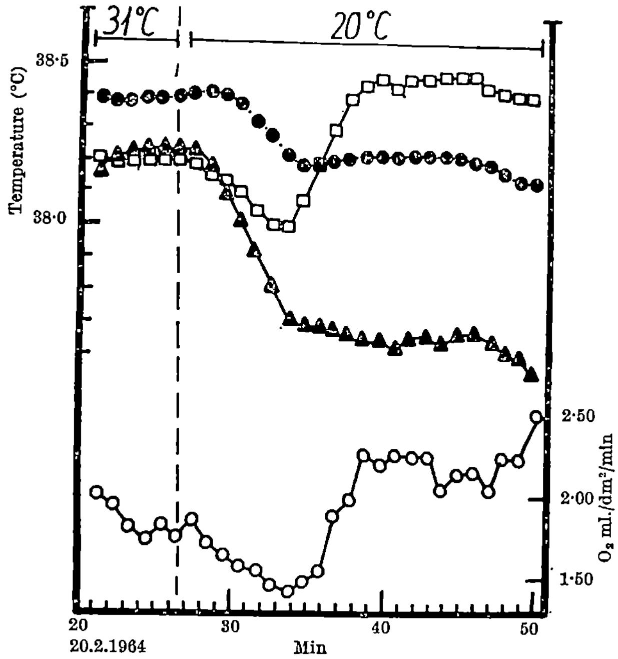

Fig. 1. Changes in colonic, brain and interscapular fat temperatures and the increase in oxygen consumption in response to transfer from a thermoneutral to a moderately cool environment in the adult rat. ●, Colonic temperature; ▲, brain temperature; □, interscapular fat temperature; ○, oxygen consumption

just beneath interscapular fat; (5) lumbar musculature. Oxygen consumption was recorded by a Noyons diaferometer permitting the registration of rapid changes[6].

Since the temperature of the lumbar musculature remained in every instance well below all the others and, in the cold, that of the thoracic muscle was found to be always less than that of the interscapular fat lying above it, these have been omitted from the figure and need not be discussed here in detail. Fig. 1 demonstrates a typical response of colonic, brain and interscapular fat temperature to exposure to a moderately cool environment. In many cases, however, the difference between colonic and interscapular fat temperature was greater in the thermoneutral environment than in this observation and brain temperature held an intermediate level between colonic and interscapular fat temperature. The increase in oxygen consumption in response to the cool environment coincided in every case with a marked and rapid increase in the temperature of the interscapular fat, and generally it became the highest in the body. Simultaneously, colonic and brain temperature ceased to fall. Following re-transfer into a thermoneutral environment, in parallel with the fall in oxygen consumption, the temperature of the interscapular fat decreased rapidly to a level below that of the colonic temperature, and in many instances also below that of brain temperature. The consecutive rise in colonic and brain temperature was followed by the interscapular fat only with a lag of several minutes. These observations seem to prove that the interscapular fat participates in thermoregulatory heat production in the adult, non-cold-adapted rat.

Effects of Deceleration on Rats exposed to Prolonged Centrifugation

Prolonged exposures of animals to simulated high gravity environments by centrifugation have been reported to repress their normal growth and attainable body mass. Matthews[1] centrifuged rats for more than a year at 3*g* and found that the body mass of centrifuged rats was appreciably lower than corresponding control animals. Similar effects for shorter exposure periods have been noted by Wunder[2] with mice and by Smith[3] with birds. The latter workers have found that when their animals were removed from the centrifuge the weight of these animals over a period of time approached that of the non-centrifuged controls. This investigation was undertaken to evaluate the effects of both an increase and decrease in gravity on rats adapted to relatively high *g* by prolonged centrifugation.

Weanling female Sprague–Dawley rats weighing approximately 84 g, usually 4–6 per cage, were placed on a 10-radial armed centrifuge and subjected to either 2·5, 3·5 or 4·7*g* depending on the radius used. The centrifuge, which had a maximum radius of 8·5 ft., was run at a constant 40 r.p.m. Animal cages were mounted on a swinging-bucket type of assembly and were illuminated by means of individual fluorescent lights automated to simulate 12 h of day and night cycling. A detailed description of the centrifuge is in preparation and will be published elsewhere. Rats were maintained on a standard laboratory rat chow ('Purina'). Water was provided by means of an inverted water bottle tray assembly. The centrifuge was stopped an average of 20 min each day to service and weigh the animals. The overall stoppage time was approximately 1·6 per cent of the total centrifugation time.

Fig. 1 (Curve *A*) shows the changes in body-weights of 4·7-*g* adapted rats removed from the centrifuge and successively exposed to normal gravity for periods of 168, 48, 24 and 9·5 h. These off-centrifuge exposures to normal gravity were spaced no closer than 2 weeks to allow sufficient time for recovery. A characteristic rapid increase in body-weight of rats removed from the centrifuge is noted with the greatest rate of increase occurring during the first 24 h. There was a progressive rise in the magnitude of this increase with each successive exposure treatment. This increase can be attributed to an enhanced rate of food and water consumption. For example, the basal food consumption of 16·4 g/rat/day for animals on the centrifuge increased to 25·3 g/rat/day when they were removed from the centrifuge for the first time. Comparable increases were noted in the other treatments.

The precipitous fall in body-weights of these rats when returned to the centrifuge was due to inanition. Rats

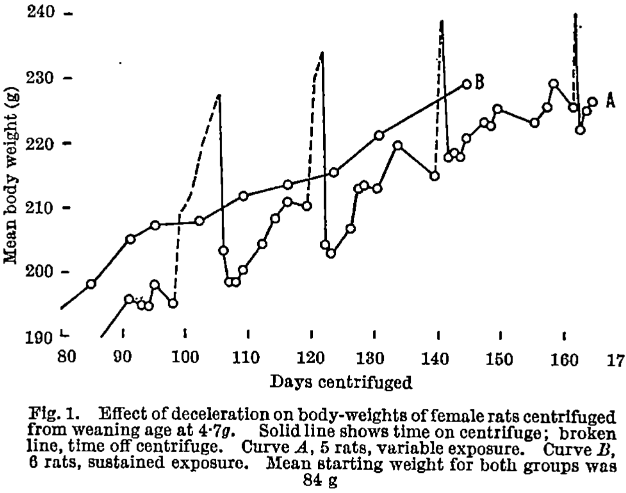

Fig. 1. Effect of deceleration on body-weights of female rats centrifuged from weaning age at 4·7*g*. Solid line shows time on centrifuge; broken line, time off centrifuge. Curve *A*, 5 rats, variable exposure. Curve *B*, 6 rats, sustained exposure. Mean starting weight for both groups was 84 g

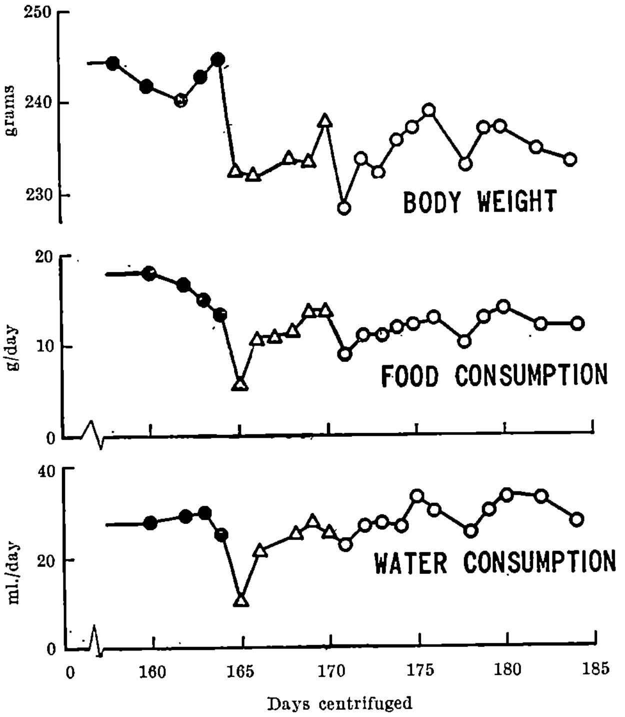

Fig. 2. Effect of increased g-loads on female rats previously exposed from weaning age to 2·5g. ●, 2·5g; △, 3·5g; ○, 4·7g. Values are means of four rats

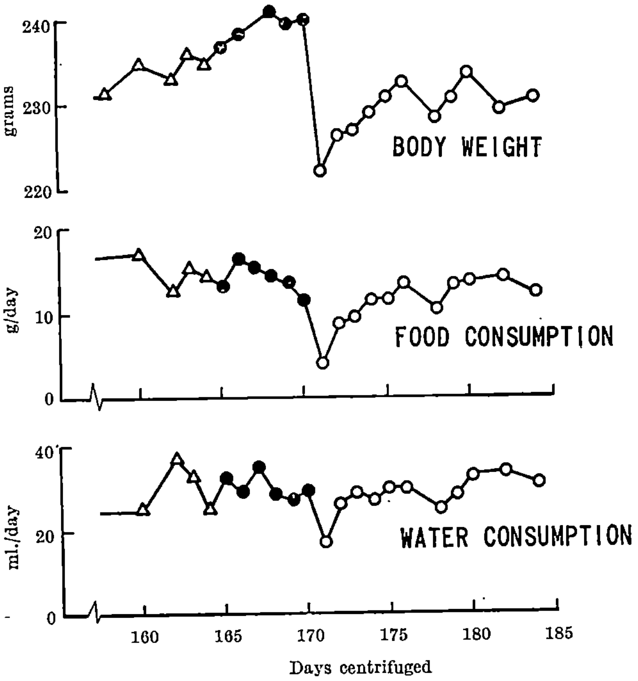

Fig. 3. Effect of decrease and increase in g-loads on female rats previously exposed from weaning age to 3·5g; △, 3·5g; ●, 2·5g; ○, 4·7g. Values are means of four rats

consumed no food or water during the first 24 h on the centrifuge following the first off–on treatment. Nine days elapsed before the food consumption of these rats was restored to the pre-treatment basal level of 16 g/rat/day. With progressively shorter exposures to normal gravity, the time required for the restoration of the basal food consumption rate was decreased proportionately. The recovery time after the 48-, 24- and 9·5-h exposure treatments was 5, 4 and 2 days respectively.

The repeated off–on treatments had no apparent effect on the overall growth rate since the growth-rate curve of these rats was similar to centrifuged rats not subjected to the off–on treatments (curve B). Preliminary growth examinations of rats exposed to prolonged centrifugation from weaning age to maturity have been reported[4] and will be presented in detail later (in preparation). Fig. 2 shows the response of rats adapted to 2·5g for 164 days and then subjected to 3·5g and 4·7g. It is observed that there is a marked decrease in body-weight, food and water consumption when the g-load is increased from 2·5 to 3·5g. A smaller decrease is noted in going from 3·5 to 4·7g. In distinct contrast, rats adapted to 3·5g for 164 days when decelerated to 2·5g show no marked change in body-weight or food and water consumption (Fig. 3). The characteristic decrement in these parameters with the imposition of a g-load is observed, however, when the rats are moved from 2·5g to 4·7g. The treatment accorded the animals in the latter experiment may be analogous to that received by terrestrial organisms when subjected to sub-gravity or weightlessness in space and then returned to Earth.

The results from this investigation indicate that deceleration is well tolerated by rats and appears not to be a stress factor. On the other hand, any sustained incremental increase in gravity has a deleterious effect on appetite and body-weight maintenance and can be considered a condition of imposed stress.

Duplex Function in the Grey Squirrel's Electroretinogram

THE grey squirrel (*Sciurus carolinesis leucotis*) was initially considered to have an all-cone retina, based on evidence obtained by light microscopy[1,2] and electroretinography[2]. In support of this, a difference spectrum obtained by reflexion densitometry was found to peak at 535 mμ[3]. Afterwards a difference spectrum of a photopigment extracted from this retina peaked at 504 mμ, however, and resembled rhodopsin[4]. Thereafter a group of diurnal squirrels including the grey squirrel was found to have double-peaked ERG spectral sensitivity curves, suggesting that there was more than one receptor mechanism in these retinæ[5]. Similar ERG results have been reported for other diurnal squirrels[6,7]. Recently, conditioning experiments on the grey squirrel demonstrated a peak wave-length sensitivity at 502 mμ (ref. 8), and rod-like in addition to cone receptors were found by electronmicroscopy[9]. This report shows that there are at least two receptor systems contributing to the grey squirrel's ERG which behave similarly to the rod and cone components of the ERGs of duplex retinæ.

The ERG has been recorded from a corneal contact lens electrode and a stainless steel needle placed under the skin on the forehead of squirrels anæsthetized with 'Nembutal'. The eye is stimulated in Maxwellian view subtending 90° of visual angle at the pupil. The light source is a well-regulated, high-pressure xenon arc lamp, the output of which can be filtered by neutral and double interference filters both calibrated spectrophotometrically. The energies of the spectral lights have been measured by a thermocouple and galvanometer. Sinusoidally flickering stimuli are obtained by rotating a 'Polaroid'

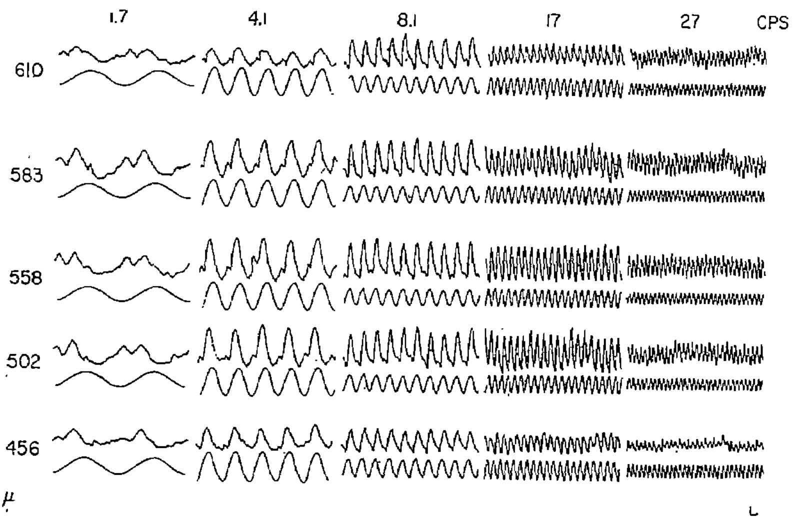

Fig. 1. ERG responses at different wave-lengths and flicker frequencies. The upper trace in each set is the ERG and the lower, the response of a photocell monitoring the stimulus. The calibration, lower right, represents 100 microvolts vertically and 100 msec horizontally. Upward deflexions indicate positivity and light on

plate in a polarized beam. The light modulation depth is 99 per cent.

Duplex function can be demonstrated by comparing the ERG responses obtained with light stimuli from both ends of the visible spectrum at different flicker frequencies (Fig. 1). With 610 mμ the ERG has a pronounced corneal positive 'off' effect and a higher peak-to-peak amplitude at 8 c/s than at lower or higher frequencies. At approximately equal response amplitudes with 456 mμ, there is neither a conspicuous 'off' effect nor amplitude peaking in the frequency response. The flicker fusion frequency is higher at 610 mμ than at 456 mμ, but if the energies in these stimuli are reduced equally, the ERG is more sensitive to 456 mμ than to 610 mμ. This can be seen in the spectral sensitivity curves obtained at low-response criteria (Fig. 2). With dim stimuli the ERG is always more sensitive to 456 mμ than to 610 mμ. With brighter stimuli the ERG response increases more rapidly at 610 mμ than at 456 mμ. With bright stimuli of high frequency the ERG becomes more sensitive to 610 mμ than to 456 mμ. This is not the result of saturation because larger responses are obtainable with wave-lengths of greater luminance than 610 or 456 mμ at all flicker frequencies.

There must be at least two receptor systems contributing to the grey squirrel's ERG, one more rod-like in the sense of determining threshold at dim light levels and being more short wavelength sensitive but slower than the other. The shift in spectral sensitivity resulting from changes in either the luminance or the flicker frequency of the stimulus parallels the Purkinje shifts of more familiar duplex retinæ.

HISTOCHEMISTRY

Alkaline Phosphatase in the Juxtaglomerular Apparatus of the Rat

Since the original observations by Goormaghtigh[1] on the structure of the juxtaglomerular apparatus of the mammalian kidney, and his subsequent observations on its endocrine function[2], the rat has been used as an experimental animal to provide material for studies of this organ. Thus examinations of enzyme changes in experimentally induced hypertension[3] and more recently granular cell changes following endocrine organ manipulation and hormone administration[4,5] have been carried out using the juxtaglomerular apparatus of the rat kidney.

In one respect at least the rat juxtaglomerular apparatus differs from that of many other mammals: that is, in the occurrence of non-specific alkaline phosphatase in a specialized layer of the cells which constitute the juxtaglomerular body. Activity at this site has been observed in four strains of laboratory rat following the application of two histochemical methods. The methods used were Lillie's modification of the calcium precipitation method of Gomori[6] and a modification[7] of the simultaneous coupling azo dye method of Manheimer and Seligman[8].

The activity which was observed varied with the strain of rat, and the intensities of the alkaline phosphatase visualized by the different methods did not correspond. This is shown in Table 1.

Alkaline phosphatase activity was located in a band of cells separating the myoepithelial cells of the juxtaglomerular body from the macula densa (Fig. 1). The afferent arteriole is surrounded by a zone of clear myo-

Table 1. ALKALINE PHOSPHATASE IN THE JUXTAGLOMERULAR APPARATUS OF THE RAT

Rat No. Strain	1 Suffield*	2 Suffield	3 Suffield	4 Sprague–Dawley	5 Sprague–Dawley	6 Sprague–Dawley	7 Fischer	8 Hooded	9 Hooded

* Inbred line from Sprague–Dawley/Wistar cross.

epithelial cells while the cells in contact with the macula densa show an intense alkaline phosphatase reaction. The nuclear staining in the cells of the macula densa and the vascular endothelium of the afferent arteriole is attributable to the nuclear staining artefact which results with the Gomori method. Comparison of the Gomori and azo dye results shows a weaker, more diffuse reaction by the azo dye method although the intensities of the reactions observed in the proximal convoluted tubules were approximately equal in both methods (Figs. 2 and 3). The variation in intensity which was observed may perhaps be due to the occurrence of isoenzymes visualized selectively by the different methods.

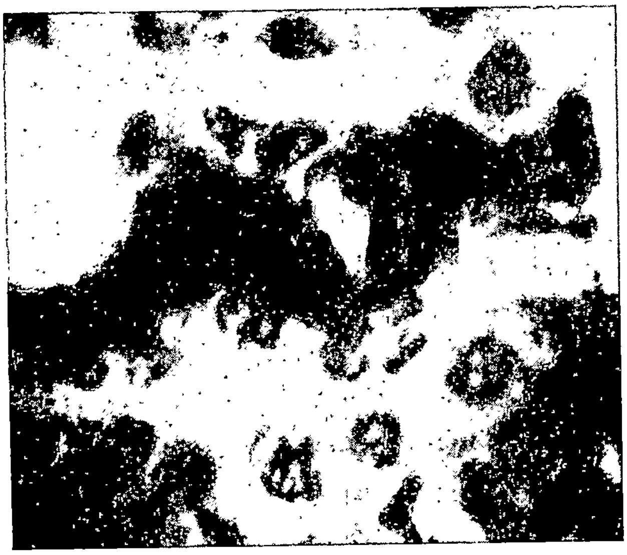

Fig. 1. Juxtaglomerular apparatus of rat. Alkaline phosphatase activity in layer of juxtaglomerular body adjoining the macula densa. Rat 4. Gomori method (×1,500)

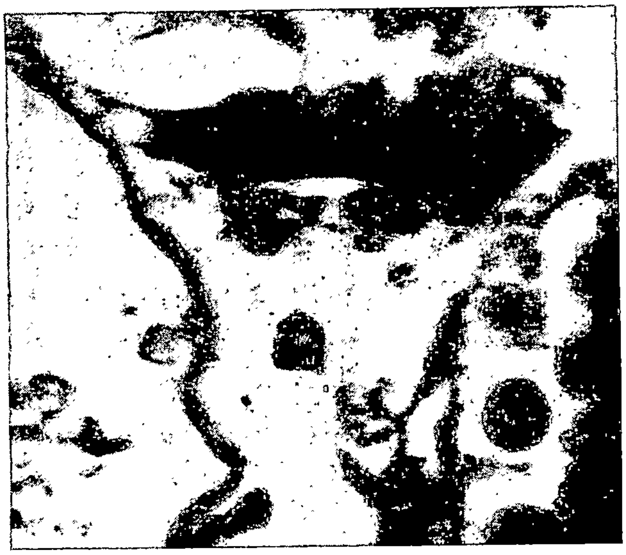

Fig. 2. Strong alkaline phosphatase reaction in the juxtaglomerular body. Rat 4. Gomori method (×1,500)

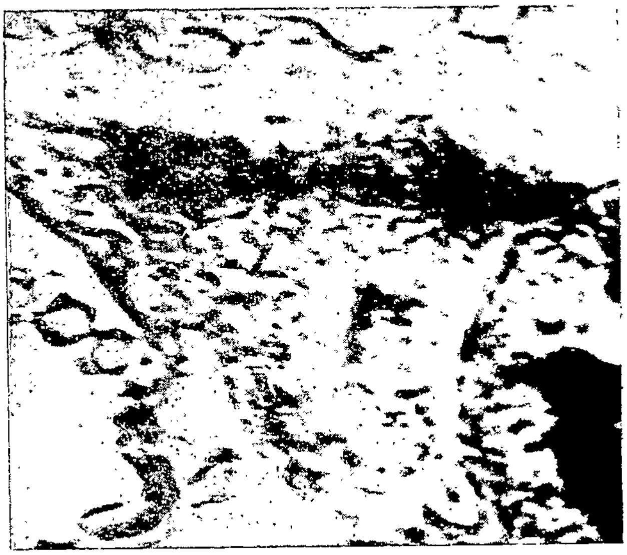

Fig. 3. Moderate alkaline phosphatase reaction in the juxtaglomerular body. Rat 4. Azo dye method (×1,500)

The occurrence of non-specific alkaline phosphatase in this location has not been observed in nineteen other species of mammal which have been examined[9]. It may be of some significance that the rat differed from the other species in the possession of well-defined alkaline phosphatase activity in the adventitia of arterial vessels. The possibility therefore exists that this specialized layer of the rat juxtaglomerular apparatus is derived from elements of the adventitia, as opposed to the myoepithelial cells derived from the media of the juxtaglomerular afferent arteriole.

It would be difficult to assign a function to alkaline phosphatase activity at this site. Perhaps this activity is concerned with the energy requirements of chemical or hormonal transfer related to the homeostatic or endocrine function of the juxtaglomerular apparatus, or perhaps more directly with the absorption of substances from the macula densa and their transference to the juxtaglomerular body.

Histochemical Localization of Alkaline Phosphatase and Adenosine Triphosphatase in the Myoepithelial Cells of Rat Salivary Glands

The histochemical demonstration of alkaline phosphatase in the myoepithelial cells of salivary glands, sweat glands and mammary glands has been reported by a number of workers[1-7].

Leeson[5,6] distinguishes between the myoepithelial cells surrounding the gland acini which form an extensive, irregularly branching network, and those of the intercalated ducts which are smaller and less extensively ramifying. He points out that the remaining portions of the duct system in rat salivary glands are alkaline phosphatase negative, implying thereby the absence of myoepithelial cells in the large ducts.

My own investigations of the distribution of alkaline phosphatase in rat salivary gland were carried out on fresh-frozen cryostat sections fixed in formol–calcium for 10 min, using naphthol *AS–BI* phosphate as substrate and coupling with fast red *TR* (5-chloro-*o*-toluidine)[8]. The results confirm Leeson's observations with regard to the myoepithelial cells of the acini and intercalated ducts. In addition, however, they clearly indicate the presence of similar cells giving strongly positive reactions for alkaline phosphatase, surrounding the striated ducts (Fig. 1). This suggests that in the rat submaxillary salivary gland, myoepithelial cells are present also in relation to the striated ducts.

Little is known of the function of alkaline phosphatase in myoepithelial cells. Certainly, its demonstration in these cells has contributed little to the understanding of their function. Although Leeson[6] states that the function of the myoepithelial cells is primarily one of contractility, there is little direct evidence in these cells of metabolic activity normally associated with muscle contraction. Indirect evidence has been provided by the work of Linzell[9], who found by direct microscopic examination of living mammary glands that the alveoli contracted following stimulation by vasopressin, oxytocin and other agents which produce smooth muscle contraction. A silver impregnation technique was used by Richardson[10], who observed structural changes in the epithelium of contracted as compared with distended alveoli and ducts in goat mammary glands. More recently, in electron microscope investigations, Scott and Pease[11] have demonstrated fibrils in the myoepithelial cells of salivary glands which they consider to be evidence that these cells can contract.

The work recorded here was undertaken in order to determine whether adenosine triphosphatase (ATPase), which is known to be present in smooth muscle, is present in the myoepithelial cells of salivary glands. Fresh-frozen cryostat sections were treated either unfixed, or fixed in formol–calcium at – 3° C for 5–10 min, and were incubated at *p*H 7·2 for 30 min at room temperature after the method of Wachstein and Meisel[8].

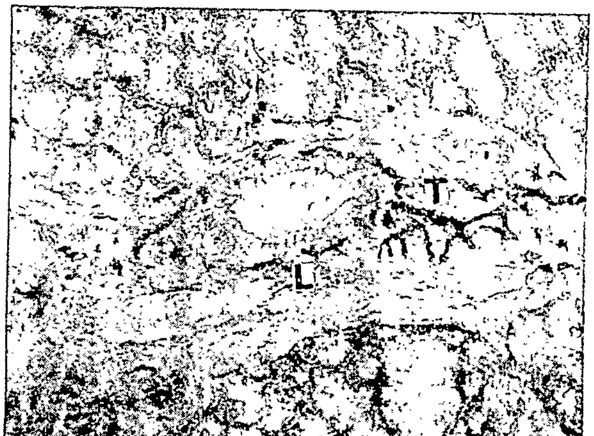

Fig. 1. Myoepithelial cells surrounding a striated duct in rat submaxillary gland. Sectioned longitudinally at *L* and tangentially at *T*. (Alkaline phosphatase; × *c*. 90)

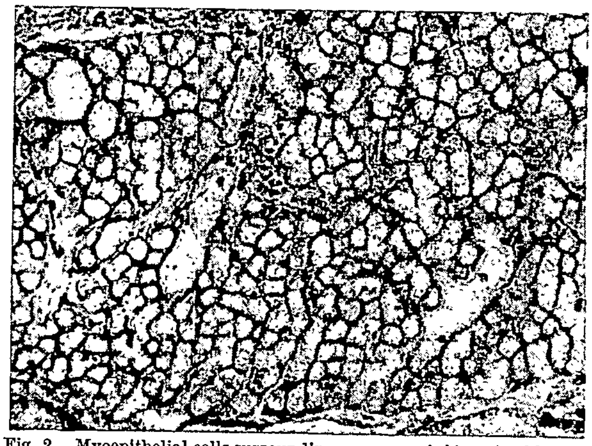

Fig. 2. Myoepithelial cells surrounding mucous acini in rat sublingual gland. (Adenosine triphosphatase; × *c*. 45)

Sections treated in this way show the presence of elongated, flattened cells which give a positive reaction for ATPase surrounding and lying in close contact with the gland acini and ducts. Their distribution is the same as that of the alkaline phosphatase-positive material in rat salivary glands and it may be assumed that they are myoepithelial cells. They form an almost unbroken ring around the mucous acini but are more sparsely located around the striated ducts (Fig. 2). Blood vessels and nerve fibres show equally strong reactions, but the acinar and duct cells themselves show no ATPase activity.

The specificity of the various histochemical reactions for ATPase has frequently been debated, as non-specific alkaline phosphatase is known to dephosphorylate ATP. The problem is discussed by Pearse[8], who concludes that, at *p*H 7·2, the *p*H involved in the Wachstein–Meisel procedure, the activity of non-specific alkaline phosphatase can be ignored. Furthermore, it was noted in this investigation that fixation at room temperature for 15 min was sufficient to obliterate any activity in these tissues, using the Wachstein–Meisel technique. As similar fixation will obviously not interfere to any marked extent with alkaline phosphatase activity in histochemical procedures, it may be assumed that the enzyme demonstrated here, using the Wachstein–Meisel procedure, is magnesium-activated ATPase and not non-specific alkaline phosphatase.

The indications are, therefore, that both alkaline phosphatase and ATPase are present in the myoepithelial cells of rat salivary glands. It is suggested that the presence of ATPase in these cells provides further evidence of their contractile nature.

This work was carried out during the tenure of a directed research bursary of the South African Council for Scientific and Industrial Research.

PATHOLOGY

Experimental Myopathic Syndrome associated with Pituitary Activation of Thymus

Formation of lymphoid follicles with light germinal centres is generally considered as being characteristic of myasthenia gravis[1] and is regarded as one of the manifestations of the auto-immune nature of this disease[2]. However, quite similar changes are induced in the thymus with no symptoms of myasthenia by subcutaneous injection of Freund's adjuvant[3] or through direct administration to the thymus of various antigens[4], proving only that the thymus is involved in every enhanced immunization process. On the other hand, the relationship of myasthenia gravis to thymus pathology is beyond any doubt; yet the nature of this relationship is obscure.

We have suggested that a mutual endocrine relationship does exist between the thymus and hypophysis. If, therefore, some known or unknown pituitary hormone carries a thymotropic function, implantation of the pituitary cells directly into the thymus of intact animals might lead to proliferation and drastic activation of the function of various thymic structures.

Experiments have been carried out on non-inbred albino rats (100–150 g). Minute pieces from 5–10 rat pituitaries have been surgically administered to the thymus of each animal.

More than 75 per cent of the experimental animals (22 out of 27) on the 14th–60th day after implantation have become ever more depressed, constrained and motionless and when set on the edge of a table usually drooped their heads for many hours. Aspiration was enforced. These symptoms as well as rapid onset of fatigue revealed a disease greatly similar to myasthenia. The tactile skin sensitivity was increased. The healing of wounds in the myopathic rats was longer than in normal ones. Electrophysiological examination shows neuromuscular disorders in this syndrome.

The following are additional symptoms observed in some individual rats: changes in the ratio of serum proteins; symptoms of hæmorrhagic diathesis; appearance in the blood of a great number of large immature cells with unsegmented nuclei; anæmia—the fall of erythrocytes number without changing the type of erythropoiesis.

Control animals injected intrathymically with pieces of brain, posterior pituitary or with the Freund adjuvant did not reveal any of the foregoing clinical changes.

Living grafts of the anterior pituitary were observed in the thymuses of some myopathic rats killed on the 25th day after implantation. These thymuses were almost normal in appearance with insignificant prevalence of lymphoid elements. Extreme hyperplasia of the lymphoid tissue with abundant germinal centres and with proliferation of plasma cells were noted in the spleen and lymph nodes.

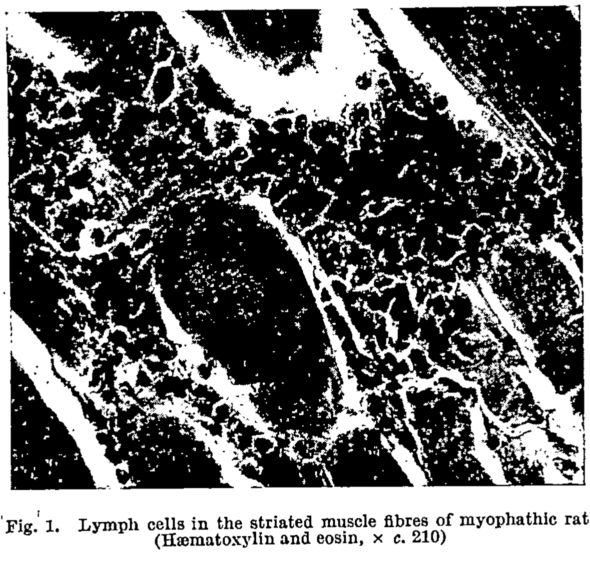

Fig. 1. Lymph cells in the striated muscle fibres of myophathic rat. (Hæmatoxylin and eosin, × c. 210)

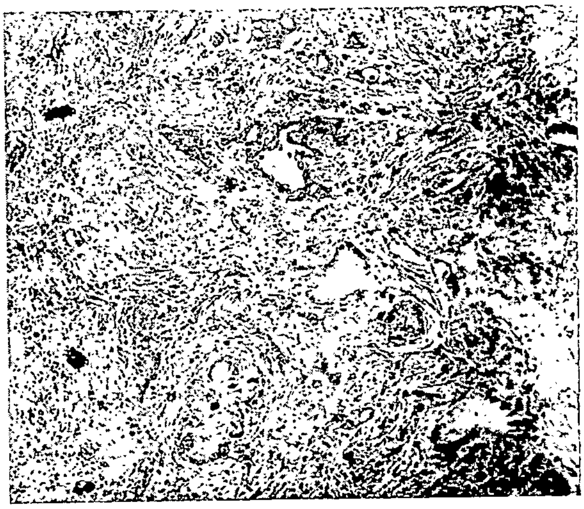

Fig. 2. Pituitary-activated thymus in cobalt-60 irradiated rat. Cavities lined with epithelium (× c. 52)

In some groups of striated muscle fibres of myopathic rats clumps of lymphoid cells and histiocytes with individual leucocytes between unchanged muscle fibres (lymph cells) were noted (Fig. 1).

In a rat with myopathic syndrome killed on the 80th day after pituitary implantation the thymus was reduced without any features of accidental involution. Ovoid lobules with nodular hyperplasia of the lymphoid tissue were noted in the upper part of the gland but without any follicles. In the lower part, lobules with thick fibrous capsule rich in mast cells, there occurred groups of epithelial and lymphoid cells surrounded by an abundance of fibrous cells. Lymph cells in the striated muscles were noted.

As to the morphological structures responsible for the myopathic syndrome, this question remains open. The lymphoepithelial thymoma-like structures previously described in this laboratory[5] have no relation to myopathic syndrome. The thymectomy of 2 rats with developed myopathia did not lead to recovery.

In some rats irradiated with cobalt-60 (200 r.) and then intrathymically implanted with the anterior pituitary unusual activation of the epithelial structure was observed which was different from that previously described[3]. The thymus was a little reduced in size, being composed only of reticular tissue in which many cavities of various size lined with monolayered epithelium were observed, some of them with pyroninophil homogeneous secretion. The whole thymus has an appearance of a secreting gland (Fig. 2). Lymphocytes were absent. Transient inhibition was observed in these rats. Such structures but less numerous were noted in control experiments with intrathymical implantation of hepatic tissue to irradiated rats. Such irradiated and pituitary activated thymuses can be used as a source for extraction of the thymus hormone. Preliminary experiments show that injection of such a thymus extract induces a marked but transient inhibition of the irradiated rats.

The foregoing experimental evidence proves the thymotropic action of the pituitary. Experiments show that this action is connected with the anterior lobe of the pituitary. Injection into the thymus of pure so far known pituitary hormones opens the possibility of deciding whether or not there actually does exist a specific pituitary thymotropin.

If the pituitary–thymus interrelation is mutual the thymus should act on the pituitary according to the feed-back principle, and experimental implantation of the pituitary into the thymus of hypophysectomized animals should not either restore or change the syndromes developing after hypophysectomy. This theory, as well as the method of stimulating implantation of one endocrine gland into another, is of general significance and may be used for the examination of any pair of organs to reveal in one of them an unknown endocrine or hormone-inhibiting function with regard to the other organ. Results of autotransplantation of the pituitary into the thymus indicate the existence of the anti-hypophyseal action of the thymus.

Artificial Heterogenization of Tumours by means of Herpes Simplex and Polyoma Viruses

We have suggested elsewhere[1] the possibility of artificial heterogenization of malignant tumours by induction in tumour cells of new antigen determinants followed by exposure of these antigens to actively acquired or passively administered lymphoid cells or antibodies.

Experiments in this laboratory on artificial heterogenization of tumours with *Salmonella* and *Staphylococcus* antigens followed by treatment with corresponding antisera proved of low efficacy. Artificial induction of new antigens in tumour cells by means of 'infectious' and 'oncogenic' viruses is described here.

In these experiments sarcoma 237 induced in C_{57} mice by means of 7,12-dibenz-(α)-anthracene and 2–5 times transplanted to these mice was used. The tumour nodes appeared on approximately the thirtieth day after inoculation. The tumour was minced without any trypsinization. The cells were filtered through 2 layers of gauze and infected *in vitro* with the herpes simplex virus (strain *El*-2 (kindly supplied by Dr. A. I. Shatkin) with low pathogenicity to mice has previously undergone about 80 passages in chick embryonic tissue cultures, titre 10^4 PFU$_{50}$ (plaque forming units)) and then implanted in mice. The cells of grown infected tumours have once more been infected with the herpes virus and implanted in mice. This procedure was carried out three times.

Tumour cells of the third passage were once more infected *in vitro* with the herpes virus and different quantities of such virus-infected tumour cells (10^4, 10^5 and 10^6 cells) were administered at a rate of 0·2 ml. to the following groups of mice: first group was twice immunized at 10-day intervals with herpes virus alone 1 month before tumour cells inoculation; the second group was immunized with vaccinia virus according to a similar schedule; the third group consisted of non-immunized mice. The same amounts of non-infected tumour cells have been injected into immune and non-immune mice.

It will appear from Table 1 that the growth of tumours infected by herpes virus was specifically inhibited in the herpes virus immunized mice.

In the next experiment the cells of sarcoma 237 were mixed *in vitro* with *SE*-polyoma virus, containing 4,960 hæmagglutinating units per 1 ml. This strain has kindly been supplied by Dr. S. Stewart. After exposure for 2 h the cells were precipitated by gentle centrifugation and resuspended in Earle's solution and injected into mice.

Table 1. Artificial Heterogenization of Cells of Cancerogen-induced Sarcoma 237 by Means of the Herpes Simplex Virus

Mice	Herpes virus-infected tumour cells			Non-infected tumour cells		
	10^4	10^5	10^6	10^4	10^5	10^6
Immunized with herpes virus	3/14*	6/15	15/15	14/14	14/14	14/14
Immunized with vaccinia virus	14/14	13/14	14/14	nt†	nt	nt
Non-immune	14/14	12/14	14/14	12/12	14/14	13/14

* Denominator indicates number of inoculated mice; numerator, number of tumours which have developed.

† nt, not tested.

Ripe tumours were minced and repeatedly treated with the polyoma virus *in vitro*. The cells treated with polyoma virus as well as non-treated control sarcoma cells were injected in doses of 10^4, 10^5 and 10^6 per mouse to the following groups of mice: (1) twice immunized with polyoma virus at 10-day intervals; (2) immunized with vaccinia virus; (3) non-immune control mice.

Absence of antibodies to polyoma virus was tested in the sera of the latter group of mice by the hæmagglutination inhibition test.

It is clear from Table 2 that growth of sarcoma 237 infected with polyoma virus is inhibited in polyoma-immunized mice.

The immunological nature of the growth inhibition phenomenon of heterogenized tumours is obvious from its passive transmission by means of lymphoid cells.

Fresh C_{57} mice were injected with polyoma virus-treated cells of sarcoma 237 (10^4 cells per mouse) and 48 h thereafter half these mice received lymphoid cells from the C_{57} mice actively immunized with the polyoma virus (10^4 lymphoid cells intravenously + 10^6 intraperitoneally). A second group of mice received the same quantity of lymphoid cells from vaccinia-immunized mice. Tumour growth in these two groups of mice was 3/14 and 14/14 respectively. The experiment shows the possibility of subsequent immunological action on the artificially heterogenized tumour.

The foregoing experiments show that tumour cells are artificially heterogenized by herpes and polyoma viruses and that immunity acts specifically on these newly artificially induced antigens. Another alternative, namely, that tumour growth is stimulated by means of virus in non-immune mice, and that this effect is inhibited in immune animals, can probably be excluded by a comparison of growth of infected and non-infected tumours.

The result of artificial heterogenization of tumour cells by means of herpes virus complies with our previous suggestion that natural heterogenization of infected cells is a general property of viruses[2].

Inflammatory lymphoid cell infiltrates common in virus disease of birds and mammals are a host reaction on the cells heterogenized by means of virus[3].

The principal problem is artificial heterogenization of ripe tumours followed by immunological treatment. For these purposes it is necessary to examine artificial heterogenization by means of various cytotropic organisms and compounds.

In one of the pioneer papers on viral oncolysis, Pierce and Rivers[4] have pointed out that growth of Brown–Pierce carcinoma infected with virus III is to some degree inhibited in rabbits immune to this virus. They regarded this effect as a non-specific one. It might be suggested, however, that here we are dealing with a specific immunological effect on an artificially heterogenized by virus III carcinoma.

Table 2. Artificial Induction of 'Polyoma' Antigen in Cells of Sarcoma 237*

Mice	Polyoma-infected tumour cells			Non-infected tumour cells	
	10^4	10^5	10^6	10^4	10^5
Immunized with polyoma virus	0/18	4/20	19/19	18/19	20/20
Immunized with vaccinia virus	20/20	18/19	20/20	nt	nt
Non-immunized	20/20	20/20	19/20	17/19	19/20

* Legends same as in Table 1.

The resistance of polyoma immunized mice to implantation of some non-polyoma tumours as reported by Sachs[5] was probably due to casual infection with the polyoma virus and subsequent artificial heterogenization of these tumours.

Note added in proof. Recently, Sjogren[6] has shown that polyoma antigen can be induced in non-polyoma tumours by a very simple method. It was shown recently in our laboratory that vacuolating virus SV_{40} can induce strong artificial heterogenization of tumours.

Protein Components of Amyloid

AMYLOID may be deposited in animal or human connective tissues in a variety of pathological circumstances. It consists mainly of protein, with up to 5 per cent of carbohydrates largely in the form of mucopolysaccharides. Previous attempts to characterize the protein moiety of amyloid have included : (*a*) Extraction with strong alkali followed by electrophoresis, revealing either α-1-, α-2-, and β-globulins with traces of albumin[1] : or α-globulin alone[2] ; (*b*) Extraction with strong alkali followed by analytical ultra-centrifugation, demonstrating a single component with a sedimentation coefficient of 6[2] ; (*c*) Extraction with concentrated aqueous urea followed by analytical ultracentrifugation, showing five fractions with sedimentation coefficients of 1, 6, 9, 16 and 23 (ref. 3); (*d*) Extraction with strong alkali followed by amino-acid analysis, which gave no precise protein identification but excluded collagen as a significant constituent on the basis of low hydroxyproline values[2]; (*e*) Fluorescent protein tracing in histological preparations, which is so sensitive a technique that trace contaminants would be revealed, has detected the presence of γ-globulin[4–6], β-1 complement[6], rheumatoid factor[6], and fibrinogen[6]; (*f*) Absorption of specific anti γ-globulin antiserum with purified amyloid substance, which produced no significant reduction in titre[7]; (*g*) Extraction with concentrated aqueous urea followed by immuno-diffusion and electrophoresis against specific antisera to albumin, γ-globulin, cæruloplasmin, orosomucoid, β-2 macroglobulin, rheumatoid factor, C-reactive protein, a pool of myeloma globulins, and whole serum ; none of these antisera precipitated the amyloid proteins[8]; (*h*) Extraction with strong alkali followed by preparation of an antiserum which, on immuno-electrophoresis against whole serum, gave precipitin arcs in the α-2 regions[8]. None of these methods has entirely surmounted the two main obstacles to precise identification of the protein components of amyloid. These are, first, the relative insolubility of this material in all but chemically vigorous reagents which are liable to degrade proteins and, secondly, the difficulty in obtaining amyloid free from incidental contamination by plasma proteins. The new method reported here appears to circumvent both these difficulties in the isolation of pure natural amyloid.

The technique involves cycles of : (*a*) brief ultrasonic disintegration into particles of macromolecular dimensions; (*b*) differential cold precipitation of the amyloid, which sometimes involves freezing, combined with numerous washings with neutral isotonic saline in order to remove all traces of incidentally trapped serum proteins. The substance so isolated is still in its original insoluble state and retains the tinctorial reactions (Schiff positivity, methyl violet metachromasia, positive congo red staining) characteristic of the parent amyloid deposits in the original tissues. The preparations from two human amyloidaceous kidneys were used to immunize rabbits and the antisera produced were analysed for their ability to precipitate human plasma proteins in immuno-electrophoresis.

Antiserum obtained with amyloid prepared from a patient with chronic syphilis reacted solely with 7*S* γ-globulin (Fig. 1). The antiserum produced by amyloid derived from a patient with chronic rheumatoid arthritis reacted with five plasma proteins ; very weakly with 7*S* γ-globulin, but very strongly with one α-1 and three α-2 components (Fig. 2). If the plasma proteins had been present in the amyloid preparations as a result of contamination from tissue fluids or blood they would most likely have been similar in both cases. However, since the antisera to each amyloid sample contained antibodies to different plasma proteins, the components revealed were probably integral with and peculiar to their respective amyloid substances. Neither sample induced precipitating antibodies to β-2-macroglobulin, to which class both rheumatoid factor and the Wassermann antibody belong[9], and thus these auto-antibodies were not components of the respective amyloid deposits. Hence, in opposition to Letterer's[10] belief regarding the pathogenesis of amyloid substance, it appears that neither of the amyloid samples tested contained sequestered products of an auto-immune reaction.

The present method of isolating amyloid, using only gentle physical means, seems to provide the substance pure and with its protein components undegraded. The findings with antisera prepared from such material may thus be accepted with less reserve than evidence obtained

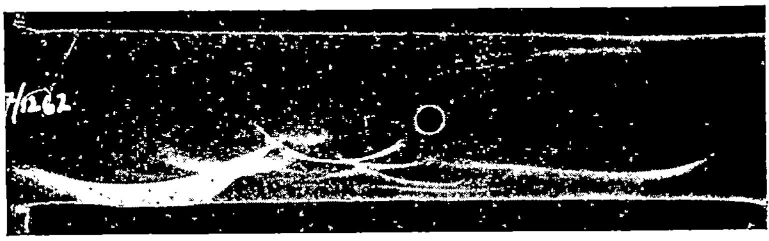

Fig. 1. *Upper trough*, antiserum to syphilitic amyloid; the only arc developed is to 7*S* γ-globulin, recognizable by its characteristic situation and curvature; *well*, whole human serum, anode to the left; *lower trough*, antiserum to whole human serum; *buffer*, borate-succinate; *p*H 8·6; M 0·05. N.B. The reduplication of the 7*S* γ-globulin lines on both sides is gel and/or Liesegang artefact

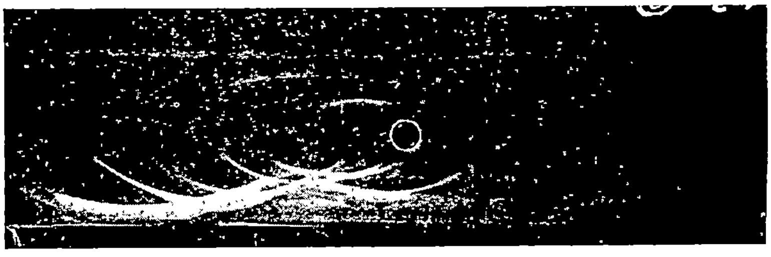

Fig. 2. *Upper trough*, antiserum to rheumatoid amyloid; the α-1 arc, two α-2 localized arcs, and an α-2 arc extending forward into the α-1 region are clearly visible. The 7*S* γ-globulin arc is too faint for photographic reproduction; *well*, whole human serum, anode to the left; *lower trough*, antiserum to whole human serum; *buffer*, barbitone; *p*H 8·2; M 0·05

by earlier techniques. While most authors are in agreement that different amyloids probably contain different proteins, there is less unanimity regarding their source. The results of the work recorded here confirm the heterogeneity of the protein components in amyloid from different sources and provide evidence that some of these proteins are derived from those normally circulating in the blood plasma.

Work is proceeding on similar analyses of other human and animal amyloids, and on the more precise identification of the alpha components revealed in the rheumatoid amyloid.

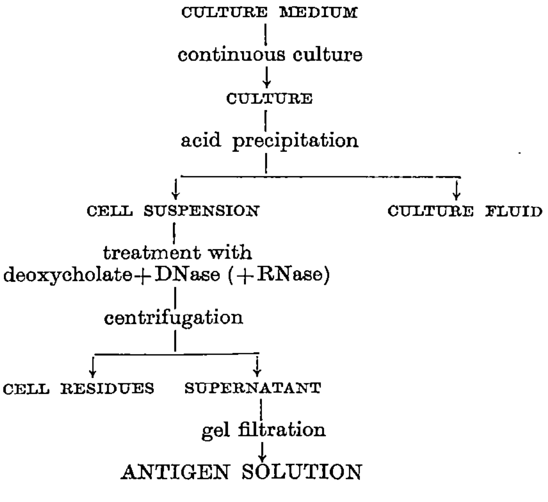
IMMUNOLOGY

Preparation of Soluble *Pertussis* Vaccine

SEVERAL suggestions have been made for isolating from *B. pertussis* the cell fraction which is responsible for immunizing man against whooping cough. Most investigators[1–4] have used some form of mechanical disintegration of the cells, but the possibility must also be considered, since the protective fraction is most probably located in the cell wall[5], that chemical solubilization of the outer layers of the cell may be a better approach.

Barta[6], using sodium deoxycholate, has shown that such an approach is possible although a reproducible process for the treatment of large quantities of cells was not considered. The process we describe here is one by which a solution of the protective antigen can easily be obtained in sufficient quantity, yielding a fairly constant starting material for further investigation.

The method is outlined as follows:



The method comprises:

(1) Continuous culture of *B. pertussis* according to the chemostat principle with a dilution rate of 0·06–0·09 h^{-1} (ref. 7). This procedure provides a suspension of cells grown under the same conditions, which is of great advantage to the reproducibility of the solubilization process.

(2) Precipitation of cells by lowering the *p*H to 3·8–4·0 as described by Pusztai *et al.*[8], followed by decantation of the culture fluids in a closed system.

(3) Treatment with 1 per cent sodium deoxycholate at 25° C and *p*H 8·0 of a cell suspension containing about 200 × 10^9 cells/ml. Barta[6], using a suspension of 20 × 10^9 cells/ml., sometimes obtained a very viscous liquid at this stage, but we have found that treatment with DNase at 25° C for 15 min reduces the liquid to a low viscosity and thus enables the next stages to be done quickly.

In some experiments addition of a very small quantity of RNase was necessary to reduce the viscosity to the desired level. An explanation of this fact may lie in variation in the RNA-content of the cell material. Unlike DNA, RNA is known to vary with dilution rate in continuous culture[9] and with age of the cells in stationary culture[10,11].

(4) Centrifugation of the treated suspension at 14,000*g* for 15 min.

Table 1. ACTIVITY OF SOLUBLE FRACTIONS COMPARED WITH THAT OF WHOLE BACTERIA

Cells prepared from culture No.	Values (I.U.) per human dose* Whole bacteria Protective antigen	H.S.F.	Soluble fraction Protective antigen	H.S.F.

			3·6	10
			3·2	8·4
			5·2	22·4

* The protective antigen was assayed in relation to the international standard for *pertussis* vaccine and the potency expressed in international units. The H.S.F. was also assayed in relation to the international standard according to the method of Preston[14] and the potency expressed in arbitrary units (ref. 15).

(5) Gel filtration of the clear supernatant in 0·025 molar phosphate buffer at *p*H 8·5. 'Sephadex *G*-75' has proved to be the most suitable. The filtration can be accomplished in a closed sterile system. Dialysis, as recommended by Barta[6], has certain disadvantages in that it takes longer and can be carried out aseptically only with difficulty; moreover, it is difficult to reduce the deoxycholate concentration sufficiently. In our gel-filtration procedure less than 20 mg deoxycholate per litre was left, this being the lower limit of sensitivity of the test which involves heating with 60 per cent sulphuric acid for 15 min and measuring in the photometer at 385 mμ. The column used was a modified version of that described by Porath[12], and is equipped with a double glass wall for working at constant temperature; it enabled 6 l. of the soluble fraction to be processed in one day.

A number of preparations of the soluble fraction have been tested in mice for protective antigen and histamine sensitizing factor (HSF) in comparison with whole bacterial suspensions. The results are given in Table 1. The lack of accuracy of the biological assay for protective antigen does not permit a precise estimate to be made of the yield, but it can safely be concluded that at least 75 per cent of the protective antigen of the whole cells is contained in the extract. The high concentration of HSF gives another indication of the close association of this factor with the protective antigen[3,13].

In the toxicity test according to the American minimum requirements for *pertussis* vaccine mice have shown no toxic reactions during the 7 days observation period.

The soluble fraction has been shown to retain its antigenic potency for at least 3 months when stored in the liquid state at 4° C. The fraction may be lyophilized but so far the method used has given rise to losses of activity of up to 50 per cent.

Further investigations are to be made to evaluate the product in pharmacological and immunological tests, and also to purify it still further.

We thank Prof. D. G. Evans (London School of Hygiene and Tropical Medicine) for his advice.

Secondary Immune Response to Bacteriophage T1 in the Shore Crab, *Carcinus maenas*

Comparative investigations of the clearance of injected bacteriophage from the circulation of several species of animal have been carried out. Clearance from the chicken, frog and from certain elasmobranch, holostean and teleost fish was very rapid and was associated with the development of neutralizing antibody[1,2]. In the cyclostomes *Petromyzon marinus* and *Eptatretus stoutii* clearance was relatively slow, and little or no neutralizing ability developed in the serum of injected animals[2]. The insect *Samia cecropia* cleared 90 per cent or more of the injected dose of bacteriophage from the hæmolymph between the second and the tenth hour, but no neutralizing activity appeared to develop[3]. Accelerated secondary clearance has been demonstrated in the chicken, the frog and in some fish, but was not tested in the insect. The following preliminary experiments were carried out to investigate primary and secondary clearance of bacteriophage in other invertebrates as part of an investigation in comparative immunology.

Bacteriophage *T*1 (10^3 'phage particles) was injected into the hæmocœle of three shore crabs (*Carcinus maenas*) which were maintained in sea water at 16°–18° C. Hæmolymph samples were taken 30 min after injection and then at fortnightly intervals. In the two instances in which the bacteriophage was completely cleared from the circulation, a further dose of 10^3 particles was injected and again the clearance was followed in fortnightly samples.

Samples of hæmolymph were allowed to clot, centrifuged and the supernatant tested for viable bacteriophage by the following pour plate technique. The hæmolymph was serially diluted in nutrient broth and 0·1 ml. of one or more suitable dilutions was mixed with 0·1 ml. of a 4 h culture of *Escherichia coli B*. The mixture was pipetted into 0·5 ml. of melted nutrient agar (0·7 per cent) at 50° C which was then poured evenly over the surface of a 1 per cent nutrient agar plate. After overnight incubation at 37° C the number of plaques was counted and from this the number of viable bacteriophage particles was calculated. Each selected dilution of hæmolymph was titrated in this way 5 times and the mean of the results taken.

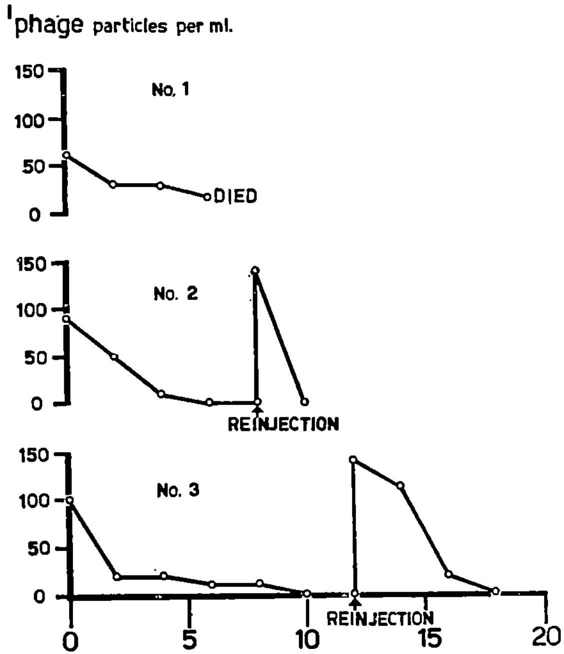

Fig. 1

Fig. 1 illustrates the decrease in bacteriophage particle counts in the three animals. Primary clearance occurred in 42 and 70 days in animals 2 and 3, respectively. Animal 1 died before complete primary clearance, but the 'phage particle counts were following a similar course to those in the other two animals. Secondary clearance was more rapid, animals 2 and 3 clearing completely in 14 and 42 days, respectively. Thus in the two instances in which secondary response was measured the rate of clearance increased by factors of 3·0 and 1·6.

Hæmolymph from crabs 2 and 3 was tested for neutralizing activity against bacteriophage *T*1 after secondary clearance of 'phage from the circulation and again 2 and 4 weeks later. No activity could be demonstrated. Although this observation suggests that the accelerated secondary clearance is mediated by a cellular rather than by a humoral mechanism, the possibility that undetected humoral factors are involved cannot be discounted.

RADIOBIOLOGY

Soluble Liver Proteins Fractionation by Zone Electrophoresis on 'Pevikon C-870'

Liver proteins have been separated by agar-gel electrophoresis into thirteen[1] and fifteen[2] separate moieties. The use of 'Pevikon *C*-870' (PVK) as supporting medium for electrophoresis has numerous advantages[3–5], and an analysis of soluble proteins in rabbit liver separated by PVK-block electrophoresis has yielded the results reported here. PVK (Stockholms Superfosfat Fabriks Aktiebolag) blocks measuring 50·0 cm × 24·0 cm × 1·6 cm; veronal buffer, pH 8·6 (0·075 M sodium barbital and 0·015 M diethyl-barbituric acid), were used throughout.

The liver (73·0 g) of a heparinized male rabbit previously injected with homologous serum proteins labelled with iodine-131 was perfused with about 2 l. of saline through the portal vein and homogenized with an equal volume of veronal buffer, 0·15μ, pH 8·6. The homogenate was frozen at − 39° and thawed six times, and the suspension was centrifuged at 34,000*g* for 90 min. The whole procedure was carried out at 2°–4°.

Protein solutions were labelled with iodine-131 (*IBS*.3, Radiochemical Centre, Amersham) according to McFarlane[6] and were equilibrated, by dialysis, against buffer solutions. At the end of the electrophoresis, performed at room temperature with adequate cooling and buffer mixing systems, the PVK block was separated into 49–50 segments 1 cm wide. The proteins in each segment were eluted with 0·15 M sodium chloride and the eluates were estimated for their radioactive and protein contents. Proteins were estimated from 540 mμ[7] absorption in a Unicam *SP*.500 spectrophotometer.

^{131}I-TCA (trichloroacetic acid final concentration: 10 per cent) soluble radioactivity as a percentage of the original radioactivity was measured in the presence of sodium iodide and of 35·0 mg of carrier bovine serum proteins.

After concentration and clarification the protein fractions were tested by starch-gel electrophoresis[8]. Agar used for double diffusion[9] was a 1 per cent solution of 'Ionagar' No. 2 (Oxo, Ltd., London) in phosphate buffered saline, pH 7·3.

Technical details about PVK-block electrophoresis have been previously described[6]. Soluble hepatic ^{131}I-proteins (2·1 g, 80 mg/ml.; ^{131}I-TCA soluble radioactivity: 4·6 per cent) were applied into a block at 10 cm from the cathodal end and electrophoresis was carried out for 44·5 h with a gradient voltage of 4·4 V/cm (current 160 m.amp).

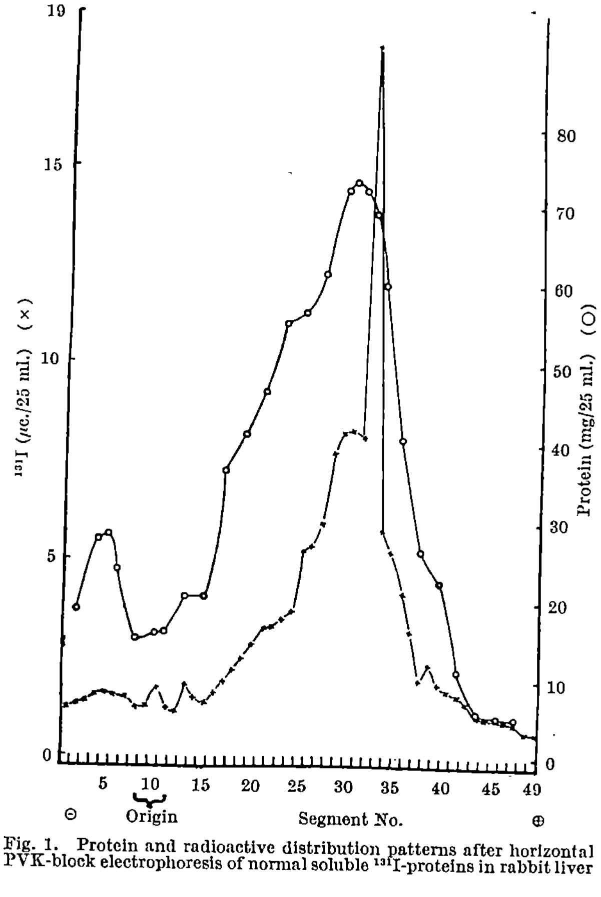

Fig. 1. Protein and radioactive distribution patterns after horizontal PVK-block electrophoresis of normal soluble ^{131}I-proteins in rabbit liver

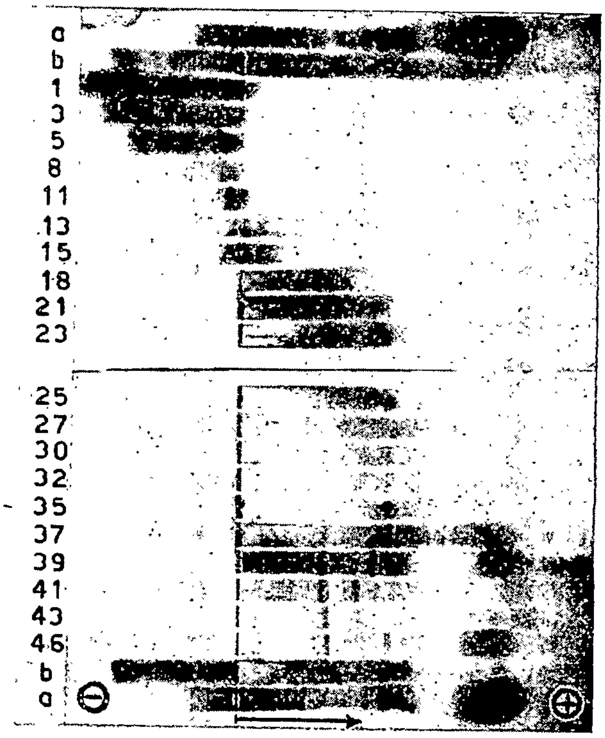

Fig. 2. Starch-gel electrophoresis (pH 8·6, 0·025 M borate buffer) of: (*a*) rabbit serum proteins; (*b*) rabbit liver soluble proteins and of rabbit liver protein fractions the numbers of which correspond to segment numbers in Fig. 1

Bromophenol blue-proteins bound had moved about 25 cm towards the anode. Fig. 1 shows the radioactive and protein contents of the PVK segments. The two profiles correspond fairly well, and therefore by measuring radioactivity the degree of separation can easily be assessed. Fig. 2 shows the electrophoretic pattern in starch gel of the separated liver protein components run compared with the original liver proteins sample and with rabbit serum proteins.

Starch-gel electrophoresis did not separate into distinct units the soluble liver proteins, whereas it helped to distinguish the separated protein fractions due to different electrophoretic mobilities, but showed in many cases the persistent complexity of the separated protein fractions. Segments Nos. 1–10 contained at least four liver protein components which moved towards the cathode, and some of these γ-globulin type proteins migrated faster than γ-globulin serum proteins, possibly because of a net positive charge under the conditions of electrophoresis. Segments Nos. 11–16 contained protein components having a low electrophoretic mobility. Segments Nos. 17–49 contained protein components all moving towards the anode. On starch-gel electrophoresis the liver protein fractions obtained from PVK segments gave at least 22 easily recognizable migrating bands. Some could be considered β-α-globulins or albumin or pre-albumin type proteins as they had the same migratory rate as corresponding protein serum fractions.

However, the soluble proteins extracted from liver should be free of contaminating blood serum proteins, because the liver, after an accurate perfusion, contained a very small amount of radioactivity due to circulating ^{131}I-serum proteins. Intracellular and extracellular serum proteins, by considering the role of the liver in plasma protein synthesis[10], could account for some of the protein bands. However, the immunological examination of rabbit serum proteins and liver soluble protein fractions, tested against a goat anti-rabbit serum, showed little, if any, contribution of serum proteins to liver protein bands.

The resolution of the liver proteins in such a high number of fractions is due, at least in part, to the possibility of large loading of protein in the PVK-block.

Exchange Labelling of 'Lipiodol' Ultra Fluids with Iodine-131 and its Intra-lymphatic Administration with a Fistula on the Thoracic Duct

Lymphangiography of diagnostic contrast media was first reported in clinical practice by Kinmonth in 1955 (ref. 1). The therapeutic significance of this method was recognized by Fischer in 1959 (ref. 2) and is gaining increasing importance. Most authors are using radioactive colloidal gold for intra-lymphatic application[3-5] and supplementary therapy to surgical intervention in the case of microscopical metastatic infiltration of lymph nodes in malignant diseases. However, recently[6-8] iodine-131-labelled 'Lipiodol *UF*' or 'Ethiodol' is preferred for this purpose.

A new method for preparing 'Lipiodol *UF*'-iodine-131 by an exchange reaction and an improved method of administration is described here.

After intra-lymphatic administration of large quantities of 'Lipiodol *UF*', embolization of this compound occurs in the lungs, occasionally causing severe to lethal complications in the patient[9,10]. A technique was elaborated experimentally which prevents these difficulties. A polyethylene tube was introduced into the terminal part of the thoracic duct on the necks of dogs. A fistula was formed through which the lymph as well as 'Lipiodol' leaves the body of the experimental animal. Figs. 1 and 2 (1, lungs; 2, para-aortal lymph nodes; 3, popliteal lymph nodes) show scintigraphs of dogs after administration of 1 ml. of 'Lipiodol *UF*'-iodine-131/10 kg body-weight (spec. act. 1 mc./1 ml.). Fig. 1 shows a dog without the fistula on the thoracic duct, in which a high activity above the lungs can be observed. Fig. 2 shows distribution of 'Lipiodol' after application of the same quantity of 'Lipiodol *UF*'-iodine-131 (relative to body-weight) by the fistula. No activity is detectable in the lungs. Fig. 3 shows the lymphangiogram of the latter dog; the popliteal and two para-aortal lymph nodes filled by 'Lipiodol *UF*'-iodine-131 can be recognized. Radioactivity in the lungs was measured also after killing the dog. The results confirmed the conclusions from the scintigraph as well as histological examination of the lung tissues.

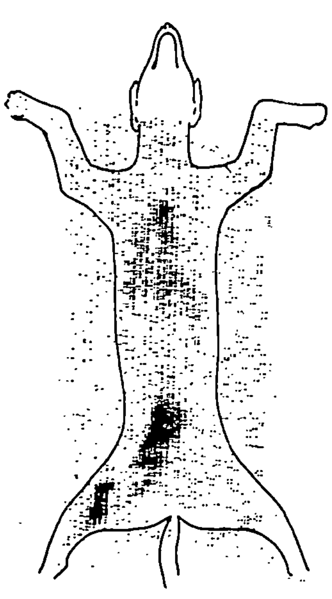

Fig. 1

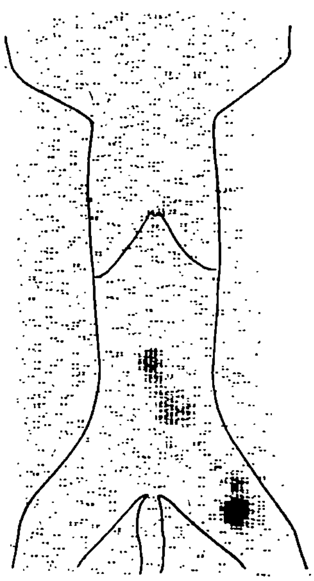

Fig. 2

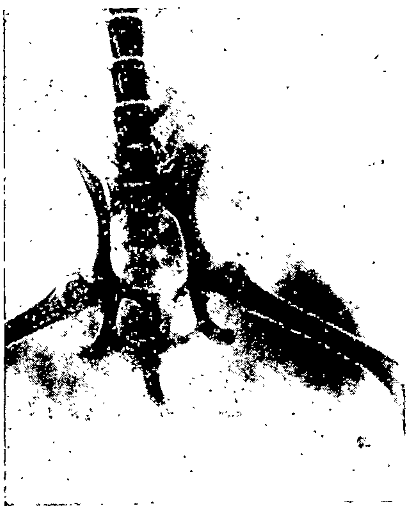

Fig. 3

Since performance of a thoracic duct fistula is simple and safe in clinical practice, this method is recommended for patients to whom large quantities of these compounds are injected.

Iodine-131-labelled 'Lipiodol *UF*' was prepared by a modified radioactive exchange method based on our previous experience with labelling of *RTG* contrast media[11] and rose bengal[12]. Two methods of exchange labelling of 'Lipiodol *UF*' (iodinated higher fatty acid ethyl esters with 38 per cent iodine content)[13] have been elaborated, the first being more advantageous.

(*a*) Exchange reaction between 'Lipiodol *UF*' and iodine-131. 0·1 ml. of 0·1 N potassium iodide, 0·1 ml. of 0·01 N sodium nitrite, 1 ml. potassium iodine-131 (10 mc.), 2 ml. carbon tetrachloride and 0·15 ml. 0·02 N hydrochloric acid are pipetted into a glass-stoppered flask and intensively stirred for 1 h. The organic phase containing the iodino-131 released is separated and washed three times with 1·5 ml. water. The iodine-131 solution in carbon tetrachloride together with a mixture of 2 ml. of carbon tetrachloride and 1 ml. of 'Lipiodol *UF*' is heated to 50°–60° in a tapered flask under reflux. The solution is then extracted twice with 2 ml. of 0·001 N $Na_2S_2O_3$, twice with 2 ml. 0·001 N potassium carbonate and twice with 5 ml. water. The carbon tetrachloride solution is evaporated *in vacuo*, dissolved in ethanol, filtered if necessary, and evaporated again. A clear oil is obtained: radioactivity 9 mc. iodine-131 (yield 90 per cent). The product is chromatographically identical with the starting material and does not contain any free iodine-131.

(*b*) Exchange reaction between 'Lipiodol *UF*' and potassium iodine-131, 1 ml. 'Lipiodol *UF*', 35 ml. of acetone and 2 ml. of an aqueous solution of potassium iodine-131 and 0·5 ml. 0·001 N potassium iodide carrier are mixed and heated under reflux for 2 h. The solvents are evaporated, 5 ml. petrol ether and 2 ml. water added and the layers separated. The petrol ether solution containing 87 per cent of the initial radioactivity is evaporated to give a colourless oil.

BIOLOGY

Resistance to Warfarin in the Common Rat

A case of apparent resistance of the common rat to warfarin occurred in 1958 on a farm in West Scotland[1], and further evidence of resistance from the same farm was given in 1963 (ref. 2). No other report on this matter is known to me.

In 1962 some difficulties arose in controlling rats (*Rattus norvegicus*) on a couple of farms in Jutland, Denmark, and some rats caught on the farms during the winter of 1962–63 were consequently tested for warfarin resistance in the laboratory. After being fed for two or three weeks on the same diet as brown rats from the rat farm of the Laboratory, they were compared with these rats in four tests, each consisting of four rats from Jutland (*J*-rats) and four rats from the rat farm (*RI*-rats). The two groups were identical in regard to sex and rather uniform in regard to weight. They were placed singly in metal cages and supplied with water from a bottle with tube at the top of the cage.

Table 1

Dose of warfarin	No. of rats *J*-rats	No. of rats *RI*-rats	No. of rats surviving *J*-rats	No. of rats surviving *RI*-rats	Average No. of days from first portion eaten to death *J*-rats	Average No. of days from first portion eaten to death *RI*-rats
Test 1 0·025% 1 ml. for 5 days	4	4	2	1	10 (2 *r*)	4·7 (3 *r*)
Test 2 0·045% 1 g for 5 days	4	4	3	0	11 (1 *r*)	6·5 (4 *r*)
Test 3 0·049% 1 g for 5 days	4	4	3	0	6 (1 *r*)	6·5 (4 *r*)
Test 4 0·024% 1 g for 5 days	4	4	4	0	—	7·3 (4 *r*)
Total	16	16	12	1		

(-*r*) = (-rats). All the dead rats had pronounced internal hæmorrhages.

In test 1 each rat had 1 ml. of a warfarin solution dripped on a piece of white bread on each of five successive days.

In tests 2–4 each rat had 1 g of a warfarin preparation mixed up in white bread on each of five successive days. When five portions had been eaten, the rats were fed with ordinary rye bread.

In test 4 the *J*-rats were survivors from tests 1, 2 and 3.

As two groups of *J*-rats, each consisting of seven rats, were received during October–November 1963, two supplementary tests were carried out.

In test 5 the seven *J*-rats from the first group were fed a bait containing 0·05 per cent warfarin. On the first day each rat was offered 30 g of the bait as the only food and more was added the following days, the rat always having a surplus of bait to eat. After 51 days the test was broken off and the amount of bait eaten was measured. One rat died in seven days with internal hæmorrhages, the other six remained sound, eating on an average 630 g bait each in the period (504–887 g).

In test 6 four *J*-rats from the second group were fed a bait containing 0·025 per cent warfarin + 0·025 per cent sulphaquinoxaline (an antibacterial agent supposed to eliminate the bacteria in the intestinal tract of the rat, and in this way reducing the amount of vitamin K, the antidote to warfarin). These rats were compared with the three remaining *J*-rats being fed on an ordinary 0·025 per cent warfarin bait.

One of the four *J*-rats died after 11 days with no sign of warfarin poisoning (inflammation of the lungs and enteritis), the rest remaining sound for 30 days, when the test was broken off. In this period each rat had eaten on an average 410 g (358–460 g).

The surviving *J*-rats from tests 1–4 plus later received rats were placed in an empty rat pen at the laboratory in order to let them breed.

Besides showing an astonishing resistance to warfarin in the *J*-rats, the test may indicate that the vitamin K-producing bacteria in the intestinal tract are not primarily responsible for this resistance.

Retino-hypothalamic Connexions in Cetacea

The existence of retino-hypothalamic neural connexions in mammalian forms has long been controversial. The more recent investigations of Blümcke[1] in the cat and guinea pig, of Frey[2] in the guinea pig and of Knoche[3,4] in man, dog and rabbit strongly suggest that a bundle of fibres leaves the optic pathway at a chiasmatic level and passes dorsalward into the area of the paraventricular nucleus of the adjacent hypothalamus and also into the posterior lobe of the hypophysis. Altman[5], using the Nauta–Gygax staining technique to demonstrate fibre degeneration following optic nerve section in the cat, observed fibres of retinal origin above the optic chiasm and in the lateral hypothalamus immediately adjacent to the optic tract. Giolli[6], on the other hand, using

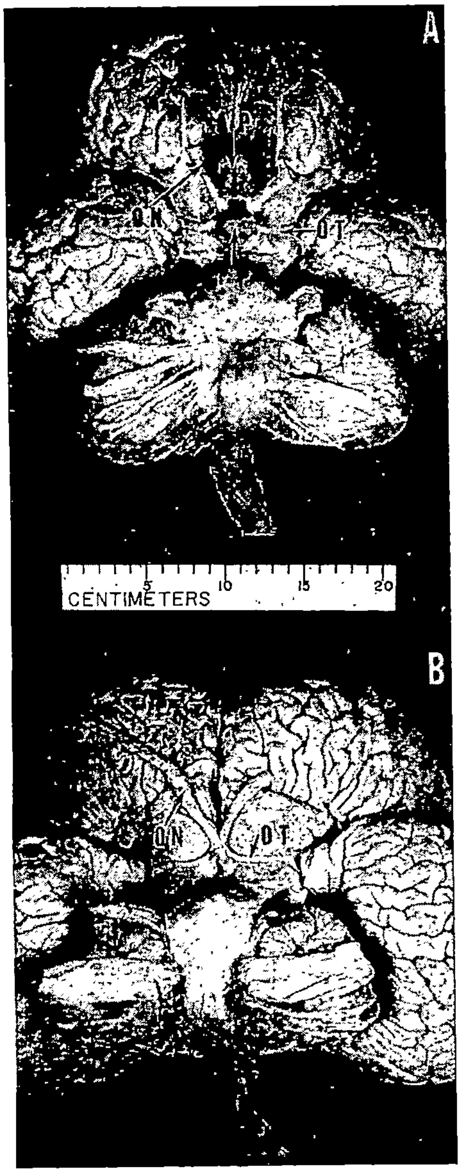

Fig. 1. Ventral aspect of cetacean brains. *A*, humpback whale (*Megaptera nodosa*) optic nerve (*ON*) and optic tract (*OT*) are indicated. Anterior lobe of pituitary gland (*AP*) reflected anteriorly from separate posterior pituitary (*PP*); *B*, sperm whale (*Physeter catodon*) depicting optic nerve (*ON*) and more slender optic tract (*OT*)

both the Nauta–Gygax and Romanes silver methods to investigate the accessory optic system in the cynomolgus monkey, found no evidence of retino-hypothalamic fibres in this form after enucleation of the eye.

In our laboratories we were impressed by the general disparity in relative size between the optic nerve and optic tract in a variety of cetacean brains. On gross observation the optic nerve always appeared to be the larger of the two structures. This feature has been observed in the sperm whale (*Physeter catodon*), fin whale (*Balaenoptera physalus*), humpback whale (*Megaptera nodosa*), Sei whale (*Balaenoptera borealis*) and in the bottlenose dolphin (*Tursiops truncatus*). This disparity in size can be clearly seen as it exists in the humpback whale (Fig. 1*A*) and sperm whale (Fig. 1*B*).

In a 401-lb. male bottlenose dolphin, with brain perfused through the aorta with 20 gallons of Windle's solution, planimetric measurements of transverse sections of the optic nerve and tract were made. Such measurements were carried out as part of the procedure[7] utilized to estimate the number of fibres in those structures. Similar data on other cranial nerves of the bottlenose dolphin[8] have been reported earlier. In this particular animal, the area of the optic nerve was $93 \cdot 0 \pm 1 \cdot 2 \text{ mm}^2$ (mean ± *S.D.*) whereas the area of the optic tract was only $74 \cdot 0 \pm 1 \cdot 9 \text{ mm}^2$. Since microscopic examination showed the fibres in both optic nerve and tract to be similar in size (Fig. 2*A* and *B*), it appeared that the increased cross-sectional area of the nerve represented a larger number of fibres.

This was confirmed by fibre counts which showed that the average number of fibres for both optic nerves in this *Tursiops* specimen was 158,435, whereas it was only 132,753 for the optic tract.

The fact that the optic nerve has a cross-sectional area exceeding that of the tract by about 25 per cent and

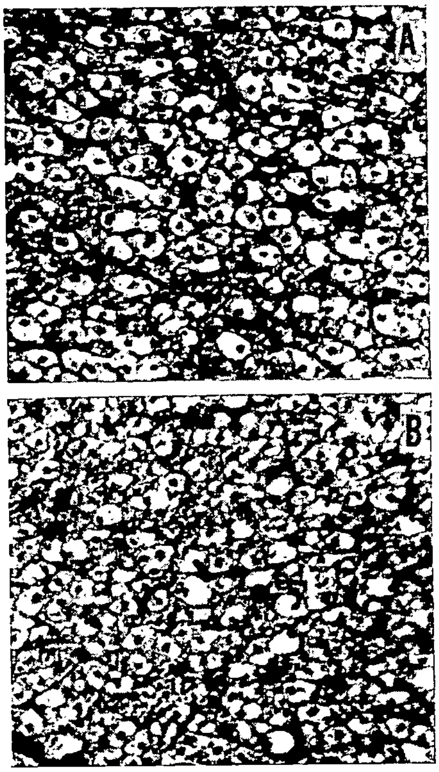

Fig. 2. *A*, optic nerve fibres; *B*, optic tract fibres. Both from bottlenose dolphin (*Tursiops truncatus*). (Alzheimer–Mann, × 440)

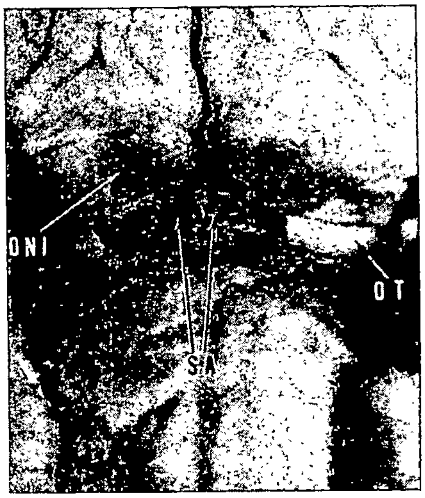

Fig. 3. Ventral aspect of chiasmatic region of bottlenose dolphin (*Tursiops truncatus*). Photograph shows the optic tracts (*OT*), severed attachment with the hypothalamus (*SA*) and impression for optic nerve (*ONI*)

contains about 19 per cent more fibres than the corresponding optic tract leaves little doubt that certain contingents separate from the visual pathways at approximately the chiasmatic level. To test this hypothesis further, the optic chiasm of one *Tursiops truncatus* was dissected from the brain base. In the process it became necessary to sever a broad tissue attachment to the overlying hypothalamus (Fig. 3).

The isolated chiasm was embedded in paraffin, sagittally sectioned at 6μ and stained by the method of Klüver and Barrera[9]. In sections through the middle third of the optic chiasm, a fibre bundle appeared to take origin from its dorsal aspect and stream obliquely upward and posteriorly into the adjacent hypothalamic area (Fig. 4*A* and *B*). As yet, chiasmatico-fugal terminations of this bundle have not been investigated in the cetacean form, but our future investigations will bear on this point.

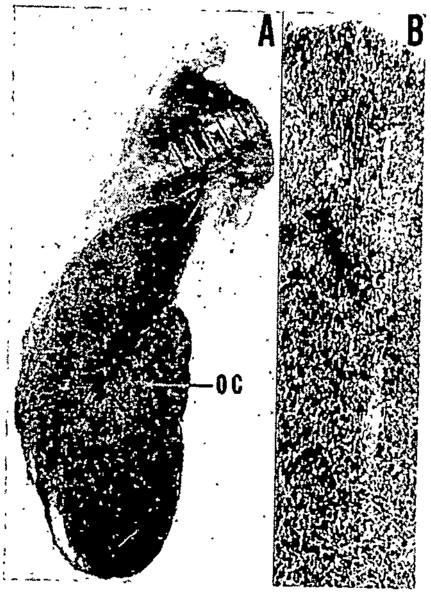

Fig. 4. Optic chiasm in bottlenose dolphin (*Tursiops truncatus*). *A*, retino-hypothalamic bundle (arrows) coming from optic chiasm (*OC*). (Sagittal section, Klüver–Barrera, × 9.) *B*, fibres of retino-hypothalamic bundle at higher magnification (× *c*. 133)

The preceding considerations strongly suggest the existence in Cetacea of direct neural connexions between the optic pathway and hypothalamus. These observations support other investigations in the literature indicating that retino-hypothalamic connexions do exist in a variety of animal forms.

Keratinized Epidermal Derivatives as an Aid to Climbing in Gekkonid Lizards

The ability of gekkonid lizards to climb up vertical glass surfaces and to hang upside-down on ceilings is a problem which has attracted the attention of numerous workers. All of them[1-3] have referred to the presence of microscopic bristles on the undersides of the feet which are apparently associated with the animal's climbing ability. However, the exact histological structure of the bristles has not been described, and even Altevogt's[3] electron-microscope observations contain no reference to the nature and histological origin of the bristles. The lack of information on the histological structure of the squamate epidermis, for the bristles are, in fact, epidermal derivatives, precluded any precise interpretation.

Sections of the adhesive pads on the feet of *Gekko gecko* (the tokay) have been examined during examination of the structure of the squamate epidermis, and some preliminary observations regarding the structure of the bristles, with comments on the present theories of the adhesive mechanism, are presented here.

Longitudinal sections of the digits show that the adhesive pads consist of a series of lamellar scales, each of which shows a slightly modified form of the typical squamate scale[4]. The adhesive bristles arise in pairs from the surface of the β-keratin on the outer scale surface[4]. Each bristle is about 90μ long and about 10μ wide at its base. Under oil immersion they are seen to be cylindrical structures of homogeneous keratin the distal ends of which have a brush-like appearance (Fig. 1). Altevogt's[3] electron-micrograph shows that there are numerous terminal subdivisions in this region.

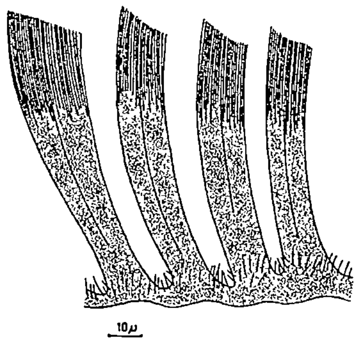

Fig. 1. Diagrammatic drawing of pairs of adhesive bristles of the foot of *Gekko gecko*

The topographical position of the pairs of bristles suggests that they are homologous with the sculpturing which characterize squamate keratin[4,5]. As has been described elsewhere[5], the sculpturings arise during keratinization by the splitting of the Oberhautchen cells: the 'split' Oberhautchen cells thus form the outer surface of the β-layer[4]. The method of formation of the adhesive bristles of the gecko's foot is more complex. The Oberhautchen of the inner epidermal generation on the underside of the foot is a very distinct cell layer the component cells of which show a striking vertical differentiation when keratinization begins (Fig. 2). The pairs of bristles are formed from without inwards, so that whereas the distal portion of the Oberhautchen cell, away from the stratum germinativum, consists of dead polymerized keratin, the proximal portion, nearest the stratum germinativum, is living, having a distinct nucleus and slightly granular cytoplasm. The bristles increase in length by the addition of new keratin at the proximal end. When the Oberhautchen cell dies and becomes fully keratinized, the bristle attains its full length (Fig. 2). It is not possible to describe the formation of the terminal sub-divisions of each bristle as they are beyond the limit of resolution of the light microscope. Oil immersion examination of the dead Oberhautchen cell body reveals thousands of even

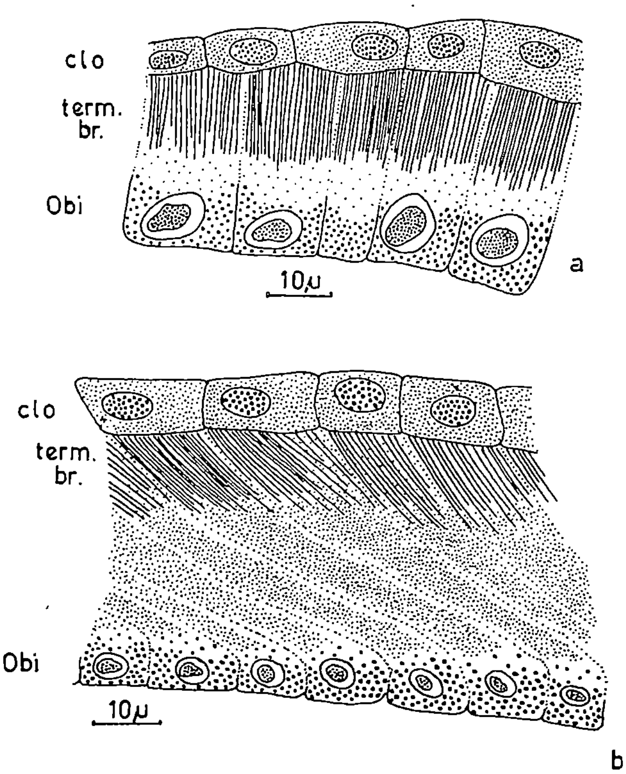

Fig. 2*a*, Diagrammatic drawing of an early stage in the formation of new bristles from the Oberhautchen of the inner epidermal generation; *b*, diagrammatic drawing of a later stage in the formation of new bristles from the Oberhautchen of the inner epidermal generation; *clo*, clear layer of outer epidermal generation; *term. br.*, terminal sub-divisions of major bristles; *Obi*, Oberhautchen of inner epidermal generation

smaller bristles on its outer surface, between the bases of the major formations (Fig. 1). The completion of keratinization of the inner epidermal generation results in the formation of a new β-layer bearing the adhesive bristles on its outer surface. These are revealed when the next slough occurs[5].

These observations are important in assessing the validity of the explanation at present accepted of the adhesive mechanism. Mahendra[2] and Altevogt[3] have put forward a theory which suggests that a gecko uses its adhesive pads in essentially the same way as a climber uses spiked boots. They believed that in the first instance adhesion is achieved by the digital claws clinging to the major irregularities in the substrate, and, secondly, that the bristles, as well as the sub-divisions thereof, reinforce the action of the claws by entering the smaller irregularities. In climbing windows the claws play no part and the adhesion results from the insertion of the terminal sub-divisions into the microscopic irregularities in the glass.

This hypothesis presents a number of difficulties in the light of the observations presented here. Neither Mahendra[2] nor Altevogt[3] referred to the length of the major bristles, nor to the relatively flexible nature of the keratin of which they are composed. The extra adhesion afforded by the spikes on a climber's boot depends not only on the individual spike's ability to engage small crevices, but also on its immobility relative to the sole of the boot. The length of the bristles affords a flexibility which would seem to preclude an analogous function. In the absence of any mechanism which would enable the bristles to actively engage the irregularities in the substrate, it is doubtful whether a direct insertion of the bristles into small crevices, as illustrated by Mahendra's[2] model, could withstand gravitational forces, particularly when the animal is walking upside-down on the ceiling. Furthermore, the effects of abrasion when the animal runs over rough surfaces, for example, stone walls, suggests that the minimum effective diameter of the terminal sub-divisions would be in the order of 0·5–0·1μ, and there is no evidence to suggest that surface depressions of this magnitude are normally to be found in window-glass. However, the presence of a bed of smaller bristles around the bases of the major structures, and the terminal sub-divisions of the latter, suggest that the adhesive mechanism is dependent on the existence of a very large surface area. In spite of the objections of Mahendra[2], the possibility of the existence of a mechanism dependent on electrostatic charges cannot be ruled out, although there is no experimental evidence to support or reject such a theory. It is difficult to see, however, what would be the significance of the terminal sub-divisions if an electrostatic charge was responsible for the adhesion. It is suggested that the present adhesion theory is unsatisfactory and that further attention should be directed to the possibility of a mechanism dependent on physical properties.

Effect of Low-salinity Water on the Vertical Migration of Estuarine Plankton

Plankton in estuaries is frequently exposed to water of different salinities in layers at different levels, with less dense low-salinity water at the surface[1]. The effects of such salinity layers on the behaviour and distribution of zooplankton have been considered by a number of workers, including in recent years Harder[2], Banse[3] and Lance[4].

Plankton samples pumped from a series of depths in the estuary of the River Test at Southampton during the day and the night indicated that the presence of low-salinity water at the surface inhibited the vertical migration of most species of estuarine zooplankton. A concentration of planktonic animals during the night appeared just below the low-salinity surface water, whereas when there was no such salinity gradient the plankton rose to the surface.

Most workers have found that estuarine plankton will not perform natural diurnal migrations in the laboratory so it is difficult to investigate this behaviour experimentally. In the laboratory most species are attracted to a light[5,6], whereas in the field they may only migrate upwards during darkness.

Lance[4] has shown in an elegant series of laboratory experiments that the strong positive phototactic responses of various estuarine copepods are reduced or inhibited by a layer of low-salinity water. The effect of salinity discontinuities on several estuarine species was reported. However, it seemed desirable to find whether diurnal vertical migrations in the field occurring in darkness were affected in the same way as these responses to a directional light stimulus in the laboratory.

For field experiments an apparatus was required, similar in principle to that designed by Sir Alister Hardy (Hardy and Paton[7]), but in which the enclosed water could come into equilibrium with the environment, and take up any outside salinity layering. Such an apparatus (Fig. 1) was constructed in the Zoology Department of the University of Southampton with the technical assistance of Mr. R. Odell. A transparent tube of square section, 1 m. long, with one side covered solely by 200 mesh/in. nylon netting was separated into three compartments by two sliding trap-doors. Mechanisms were devised for injecting a previously caught sample of living zooplankton and for closing the trap-doors while the apparatus was submerged. The apparatus was designed so that it could be raised without losing the enclosed water through the panels of

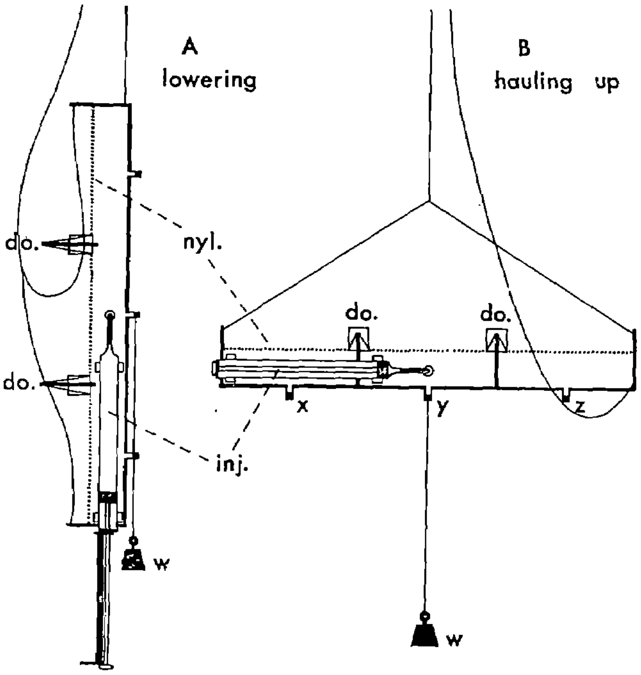

Fig. 1. Apparatus for studying the vertical migration of plankton. *A* shows the position in which it is lowered into the water with the trapdoors (*do.*) open, and a previously caught sample of plankton in the injection mechanism (*inj.*). Water is taken up freely through the panels of nylon netting (*nyl.*). The apparatus is left down for 30 min after injecting the plankton into the main tube before closing the trapdoors (*do.*). *B* shows the apparatus being hauled up horizontally so that the enclosed water is not lost through the panels of nylon netting (*nyl.*), but can be drained separately from the outlets (*x*, *y* and *z*). The weight (*w*) holds the apparatus steady in either position

netting. The water can then be drained from the three compartments separately and the percentages of each species in the upper, middle and lower compartments counted. Sharp salinity discontinuities were produced by surrounding the upper chamber only, by a metal cylinder made from a sawn-off drum, and running fresh water into this, where it was held as a floating layer. The cylinder was large enough in diameter to avoid shading the tube. Slight salinity gradients were also obtained in experiments under completely natural conditions. Several estuarine species appeared to exhibit natural vertical migration patterns in this apparatus and the effects of low-salinity water on their migrations could be determined.

Experiments were carried out using this apparatus in estuaries at Hermanus and Milmerton near Cape Town, with the estuarine copepod *Pseudodiaptomus hessei* (Mrázek)[8]. Groups of experiments in sunlight, shaded daylight, darkness and just before dawn were performed to determine the normal behaviour of the animals in salinities of 24·0, 35·0 parts per thousand. Two further groups of experiments in sunlight and darkness were then done with the top chamber of the apparatus surrounded by water of salinity of 8·5–19·0 parts per thousand. 1,000 and 3,000 *Pseudodiaptomus* were used in each of the six groups of experiments.

In the absence of a low-salinity layer the mean percentage of *Pseudodiaptomus* in darkness and before dawn was greatest in the top chamber, less in the middle and least in the bottom chamber. (Mean in the top chamber, 53·8 per cent; range 41·2–73·6 per cent.) In sunlight and shaded daylight the mean percentage was least in the top chamber, greater in the middle and greatest in the bottom. (Mean in top chamber, 23·9 per cent; range 10·1–36·8 per cent.)

In the presence of the low-salinity layer described here the percentage of *Pseudodiaptomus* in the top chamber, which was above the salinity discontinuity, was less than 1·0 per cent in all cases both in sunlight and in darkness. There was thus an almost complete inhibition of migration into the water of lower salinity, despite the fact that *Pseudodiaptomus hessei* may at times be found living naturally in water of equally low salinity[8], where there is no sharp salinity discontinuity. No consistent differences in the behaviour of the sexes or developmental stages of *Pseudodiaptomus* were apparent in these experiments.

Diurnal vertical migration must be of profound significance to have evolved in almost all planktonic animals. Its survival value to estuarine planktonic animals is probably in helping to maintain their position in the estuary. Complex current patterns occur in estuaries, where there are usually tidal oscillations and a net surface outflow of low-salinity water, and a compensating influx of saline water along the bottom which maintains the salinity gradient[9]. By performing vertical migrations, the planktonic animals drift alternately upstream and downstream, tending to maintain their position in the estuary[10]. In the case of river floods, however, the plankton would be in danger of being swept out to sea if it rose to the surface. The inhibition of migration produced by a strong salinity discontinuity would, however, prevent this occurring. This may well be the reason for the evolution of this particular behaviour pattern. This behavioural mechanism would also reduce the coefficient of reproduction[11], required to maintain a zooplankton population in an estuary, for a given exchange ratio of water escaping seaward at each tidal cycle.

I thank Prof. J. E. G. Raymont (Southampton) for advice and facilities, and Dr. R. Bainbridge (Cambridge) and Dr. Joan Lance (Hull) for advice.

Relation of Electrical Resistance to Vigour of Apple Scions

THE size attained by a scion apple tree grafted to a clonal rootstock may be modified by interaction between them; but this size is primarily an expression of rootstock effect, and it is usually similar to that of the unworked stock. The vigour rating[1] assigned to the latter is stated in terms of its effect on the ultimate size of scions.

Two electrolytic methods, namely, one involving extraction by either ethanol and/or water and the specific conductance of the extract, and a needle electrode probe method which is applied to living shoots, have identified the accepted vigour of a number of apple rootstocks. Dwarfing and vigorous stocks had high and low specific conductance[2,3], and low and high electrical resistance[4], respectively. This communication examines resistance data from living shoots of 3 scion varieties of apple grafted to 5 apple rootstock varieties.

The accepted vigour ratings 2, 4, of the rootstock clones in the experiment were as follows : *M* (Malling) IX, very dwarfing ; *M* VII, semi-dwarfing; *M* I, vigorous ; and *M* XII, and the Ottawa stock, *Malus robusta* No. 5 (hereafter referred to as *R* 5), very vigorous. The preceding were grafted to each of 3 scion varieties classified in respect of self-vigour as follows: 'Toshkee', semi-dwarf ; 'McIntosh', semi-vigorous ; and an 'Ottawa' selection, 0-2016, very vigorous. Growth and resistance data were obtained when the scions had attained the age of 5 years.

Table 1 gives averaged growth results obtained in October for each of the three varieties of scion trees on the various rootstocks. The heights of 15 trees in each rootstock/scion combination were measured in feet from ground-level, and their trunk circumference in inches at 1-ft. above the ground. The results for each scion variety reveal a direct relationship between height and rootstock vigour, and a similar relationship between circumference and rootstock vigour excepting in the case of the variety 'Toshkee'. On a particular rootstock both the height and circumference of the very vigorous scion 0-2016 were invariably greater than those of either 'McIntosh' or 'Toshkee'. The height of 'McIntosh' exceeded that of 'Toshkee' excepting in the case of the combination 'Toshkee'/*M* XII. The circumference of 'Toshkee' was slightly greater on both rootstocks *M* IX and *M* XII. Scion means for both height and circumference were in the order of accepted scion vigour. Similarly rootstock means identified in the true order of rootstock vigour.

The electrical resistances of living twigs of the previous year's growth of the scion varieties, 8 mm in diameter, were measured in the field on October 5 and November 5 by means of a portable, battery-powered Bouyoucos bridge and steel needle electrode probe assemblage according to procedures[4] previously described. The electrodes, 0·7 mm in diameter, had a tip separation of 7·0 mm. Their penetration of 2·5 mm ensured complete passage of the bark, which becomes progressively thicker with age of shoot. Air temperature ranged from 20° to 28° C; but it must be pointed out that air temperature is one of the least influential factors affecting resistance readings made on living shoots[4]. The averaged results given in Table 2 represent results from 2 twigs on each of 4 trees in each combination of rootstock and scion varieties.

Inspection of the results in Table 2 generally, and of rootstock means in particular, reveals no consistent pattern of electrical resistance attributable to rootstock effect. That the rootstock *per se* had no significant effect on the resistance of the scion grafted to it is further indicated by an analysis of variance and application of the Duncan multiple range test[5] to the data. However, the interaction between the rootstock and the scion was statistically significant at the 5 per cent level.

Table 1. Heights and Circumferences of Trees of Three Apple Scion Varieties grafted to Five Apple Rootstocks

Rootstock		Scion		Rootstock mean
	'Toshkee'	'McIntosh'	0–2016	
		Height (ft.)		
M IX	4·5	5·0	6·1	5·2
M VII	5·0	6·1	6·3	5·8

R 5	5·8	5·9	6·8	6·2
Scion mean	4·7	5·0	5·6	

Table 2. Electrical Resistances (each × 100 ohms) of Living Shoots of Three Apple Scion Varieties grafted to Five Apple Rootstocks

Rootstock		Scion		Rootstock mean
	'Toshkee'	'McIntosh'	0–2016	
		Oct. 5		
M IX	267·0	242·0	270·0	259·7
M VII	212·0	232·0	246·0	230·0
M I	213·0	246·0	258·0	239·0
M XII	230·0	243·0	280·0	251·0
R 5	266·0	254·0	277·0	265·7
Scion mean	237·6	243·4	266·2	
		Nov. 5		
M IX	264·0	259·0	266·0	263·0
M VII	283·0	330·0	332·0	315·0
M I	312·0	292·0	359·0	321·0
M XII	224·0	248·0	271·0	247·7
R 5	253·0	261·0	282·0	267·0
Scion mean	267·2	278·0	302·0	

L.S.D., between scion means: Oct. 5, 5 per cent level, 19·30; 1 per cent, 28·07. Nov. 5, 5 per cent, 24·83; 1 per cent, 36·12.

There were no significant differences attributable to date of sampling. On each of the two dates there existed a direct relationship between self-vigour of scions and their mean resistances. Low resistance was associated with semi-dwarfness and semi-vigour, and high resistance with extreme vigour. The mean scion resistance of 0-2016 differed significantly from those of 'McIntosh' and 'Toshkee', but there was no significant difference between the latter two. The latter result appears attributable to the proximity of 'Toshkee' and 'McIntosh' in the classification scale.

From this experiment it appears that, whereas the height and circumference of a scion apple tree tend to identify the vigour of both the scion and its rootstock, the electrical resistance of living scion shoots is markedly affected by the scion itself, and tends to identify only the accepted self-vigour of the scion variety.

Feeding of Vitamin C to Tomato Stems and Leaves

Branches of tomato plants ('King Humbert' variety) can absorb, without any apparent ill-effects, large quantities of ascorbic acid (0·1 per cent in tap water). In this solution, oxidation does not proceed very quickly; moreover, the vitamin C content remains constant. In July, in two days, 205* mg were absorbed per 100 g fresh weight; in October, 332 mg per 100 g fresh weight[1–3].

Vitamin C, thus absorbed in the form of ascorbic acid, partly disappears during the absorption itself: in July, the immediate determination found in the plant an excess over the controls of 115 mg vitamin C per 100 g fresh weight, that is, 56 per cent of the quantity absorbed; in October, of 129 mg vitamin C per cent fresh weight (39 per cent of the absorbed vitamin).

For the larger part at least, vitamin C is absorbed as ascorbic acid; it can be found as such in the plant, or, in various percentages, as the non-reducing form. In July, the excess of 115 mg vitamin C contains 95 mg (that is, 83 per cent) ascorbic acid. In October the excess of 129 mg vitamin C per cent g fresh weight was 97 per cent ascorbic acid.

If after two days' absorption of the ascorbic acid solution this solution is replaced by tap water, the excess of vitamin C over the controls does not exceed 29 mg per cent g fresh weight. As 158 mg (per cent g fresh weight) were absorbed, only 18 per cent of the absorbed quantity is found in the plant. These 29 mg vitamin C contain 23 mg ascorbic acid (that is, 79 per cent).

In July, after two days' absorption of the solution the vitamin C content in the stem and in the stalk of the leaves is 84 mg per cent g fresh weight: in the control at the same time, it is 27 mg. Thus the content in the experiment is about three times the content in the control. In the flat parts of the blades, the figures are much higher —experiment, 292 mg per cent g fresh weight; control. 84 mg. The content in the blade is about 3·5 times the content in the control.

* All figures given here are means.

If after two days absorption the solution is replaced by tap water for three days, a large part of the absorbed vitamin C disappears; the content in stem and stalk falls to 45 mg (control, 30 mg) per cent g fresh weight: in the flat part of the blades, to 147 mg (control, 91 mg) per cent g fresh weight: the ratio to the control is thus about 1·5 for both. The distribution of the excess of vitamin C in the experiment is fairly uniform with the distribution of the vitamin in the control, in both cases.

In October, concentration in the stem after absorption for three days rose to 75 mg per cent g fresh weight (control, 26 mg) and in the whole leaves to 223 mg per cent g fresh weight (control, 44 mg). At the end of the experiment the concentration is 3 times the control in the stem, 5 times the control, and more than twice the concentration in the solution, in the whole leaves. Water is always a little more abundant in the experimental plants than in the controls, but this is of little consequence.

At the end of the last experiment, after absorption of tap water for three days, the concentration of vitamin C in the stem is still higher than in the control: this fact points to the incorporation of the excess of vitamin C in the tissues, the increase of concentration in the stem being not merely an appearance resulting from the presence of the solution moving in the vessels.

There is a very sharp difference between the composition of vitamin C in the two kinds of organs: in the leaves, specially in the leaf blades, all the vitamin C absorbed can be in the form of ascorbic acid; in mg per cent g fresh weight 273/292 (control, 68/87) and 217/223 (control, 31/44). In the stem the proportion of ascorbic acid in vitamin C is always much lower: 42/84 (control, 14/27) and 46/75 (control, 7/26). It seems that oxidation in the stem is followed by reduction in the leaves, most probably in the blades.

The absorption of a solution of ascorbic acid (0·5 per cent in tap water) can also be brought about by means of a wick set as a seton in a slot cut in the stem of a normally rooted tomato plant. The results are less regular; but sometimes there is an important increase of the vitamin C content in the stem and the concentration may be lower above the seton than below it.

VETERINARY SCIENCE

Comparative Digestive Capacities of *Bos taurus* and *Bos indicus* Cattle as affected by Intake of Feed

A comparison of the productivity and efficiency of *Bos taurus* and *Bos indicus* cattle in an environment intermediate to those in which the two species developed was carried out over a 3-year period and reported in 1963 by Howes *et al.*[1]. Using these data it is possible to correlate and regress the apparent digestive coefficients with nutrient intakes (Table 1) for the two bovine species.

All correlation coefficients are highly significant and indicate that the coefficients of apparent digestibility are significantly correlated with the intake of dry matter, protein and gross energy for both species. However, the individual correlation coefficients for the 'Herefords' were consistently larger, although not significantly greater than those for the 'Brahmans', which may be interpreted to indicate that the digestibility of dry matter, protein and energy are more closely related to intake in 'Herefords' than 'Brahmans'. Compared with the 'Brahmans', 'Herefords' over the past century have been subjected to much selection for growth and feed efficiency. This may be the reason for the closer association between intake and digestion for the 'Herefords'. If the correlation between intake and digestion for the 'Herefords' was truly superior, it would indicate a greater efficiency in beef production.

Table 1. Correlation Coefficients and Regression Equations for Intake and Digestion of Dry Matter, Crude Protein and Gross Energy

	Correlation coefficients 'Hereford'	'Brahman'
Dry matter	0·67*	0·62*
Crude protein	0·91*	0·89*
Gross energy	0·76*	0·59*

	Regression equations (*S.E.* in brackets)
Dry matter:	
'Hereford'	$X_1 = 46\cdot2490 + 0\cdot0028\ X_2$ (0·0007)
'Brahman'	$X_1 = 45\cdot9667 + 0\cdot0030\ X_2$ (0·0009)
Crude protein:	
'Hereford'	$X_1 = 19\cdot4490 + 0\cdot0498\ X_2$ (0·0053)
'Brahman'	$X_1 = 29\cdot0271 + 0\cdot0391\ X_2$ (0·0047)
Gross energy:	
'Hereford'	$X_1 = 40\cdot3030 + 0\cdot7805\ X_2$ (0·1577)
'Brahman'	$X_1 = 43\cdot1136 + 0\cdot6094\ X_2$ (0·2175)

* $P < 0\cdot01$. X_1, coefficient of apparent digestibility. X_2, total daily intake.

Based on these investigations the regression equations reveal that the interrelationships for the dry matter and energy measures are similar for both species. However, the relationship for protein is markedly different for the two species ($P < 0\cdot05$). The superior ability of 'Brahman' females to digest crude protein has been discussed in detail elsewhere[1]. Ashton[2] has recently indicated that 'Brahman' steers have a superior coefficient of apparent digestibility for nitrogen. It is appreciated that the fæcal nitrogen involved in these investigations included undigested feed residues, unabsorbed but digested nitrogen, nitrogen secreted from various sources into the alimentary tract, nitrogen from cellular debris from the tract wall and nitrogen from undigested bacteria. No satisfactory system for separating these components has been developed.

Attempts to classify the origins of fæcal nitrogen usually involve more assumptions and errors than they eliminate.

Bos indicus cattle developed in the tropics appeared to possess fundamental digestive and other advantages for tropical beef production[3]. Since crude protein is comparatively low in tropical forages, this may be the result of adaptation. With suitable management and selection, it is possible that tropical cattle production would eventually benefit more from the selection of indigenous types rather than attempts to adapt temperate species to environments for which they are not well suited.

ENTOMOLOGY

Accelerating and Inhibiting Effects of Crowding on Sexual Maturation in Two Species of Locusts

Isolated pairs of *Locusta migratoria* (R. and F.) kept in optimum laboratory conditions may begin to copulate seven days from their emergence as adults, and the majority of females lay their first egg-pods before the 14th day of adult life[1]. Isolated pairs of *Schistocerca gregaria*

Forsk.) kept in the same conditions seldom copulate or viposit before the fourth week of adult life, and maturaion is frequently delayed for long periods[2]. Crowding ccelerates maturation in *Schistocerca* but retards it in *ocusta*. This difference between two acridids of similar regarious habit seemed anomalous. However, the bservation that continuous crowding of *Schistocerca* vith very young individuals, or fledglings, less than 8 lays old retards maturation suggested that the difference etween the two species might be mainly one of timing[3]. his suggestion is confirmed by the results of the following xperiment which show that in *Locusta*, as in *Schistocerca*[3], nature males exert an accelerating influence on the naturation or readiness to copulate of young males.

Six groups of 10 newly emerged pairs of *Locusta* were et up and three of them were seeded each with two mature nales. The times from emergence until the first copulation of ach experimental male was noted and any male copulating n the non-seeded groups was at once removed and replaced by a female of the same age as the others in the group. The copulation times of the males were as follows:

Groups with mature males	Groups without mature males
13·5 ± 1·7 days	19·3 ± 6·5 days
14·1 ± 1·4 ,,	17·5 ± 2·7 ,,
13·6 ± 1·6 ,,	25·2 ± 3·5 ,,

The average of 13·7 ± 1·5 for all males in the seeded groups differed significantly from that of 20·7 ± 5·5 for the non-seeded ones ($t = 6·566$, $P < 0·001$). Also the average for the most rapidly maturing non-seeded group differed significantly from that of the most slowly maturing seeded group ($t = 3·377$, $P < 0·01$). The synchronizing effect of the mature males on the rates of maturation was, as in *Schistocerca*, very well marked.

In both species, therefore, the young locusts have an inhibiting effect on male maturation and the mature ones have an accelerating effect. The retarding effects of crowding are counteracted by the stimulating effect of the first males which become mature, and maturation is thus synchronized. When young individuals are crowded together there comes a point where the balance is switched over from inhibition to stimulation. In *Schistocerca* this point is reached during the second week of adult life, probably before the crowded males are fully mature, and before any but the most precocious isolated individuals are mature. In *Locusta*, on the other hand, the inhibitory period lasts beyond the second week while most isolated individuals become mature early in the second week. The net result of these opposing differences in the duration of the inhibitory period and in the characteristic maturation time of isolated individuals is that crowding retards in *Locusta* and accelerates in *Schistocerca*.

In *Schistocerca* the accelerating influence of mature males is due to a chemical substance or pheromone secreted by the epidermal cells of the male at maturity[4]. The stimulating agent in mature *Locusta* males has not been isolated but it may safely be assumed to be a pheromone as in *Schistocerca*. There is as yet no direct evidence as to the nature of the juvenile inhibitor in either species but there are strong indications that it is also a pheromone. In general, crowding stimulates activity. Yet older males of *Schistocerca*, whether mature or immature, show depressed activity when permanently crowded with fledglings and become more active when temporarily isolated or crowded with each other. If permanently isolated they show depressed activity when temporarily crowded with fledglings and increased activity when crowded with each other[5]. Since the fledglings are themselves very active, locusts crowded with them are subjected to far more tactile and visual stimulation of a type which normally induces activity than they are when isolated. The inference follows that depression of activity is a response to some non-mechanical, non-visual and therefore presumably chemical stimulus. High activity is associated with rapid maturation in males[5] and enforced activity stimulates ovarial development in females[6]. Although depression of activity in older males may be a response to the same stimulus as that which inhibits maturation it is improbable that delayed maturation is the direct result of depressed activity. During the first two weeks of adult life, by the end of which time ordinary crowded *Schistocerca* are normally maturing, males crowded with fledglings are as active as those crowded with older individuals and more active than isolated ones[5].

In *Schistocerca* the pheromone also has a stimulating effect on ovarial development and on readiness to copulate in the female[3,7]. (As is usually the case in insects spermatogenesis in the male is under independent control and is dissociated from readiness to copulate; spermatozoa appear in the seminal vesicles within 10 days from emergence.) Oviposition in virgin females is stimulated by pheromone action but still more so by copulation[3], and where both sexes are present the effect of the pheromone on oviposition is mainly indirect through acceleration of copulation. The effect on the female was not tested in the present experiment with *Locusta*. The females in the seeded groups certainly copulated with the mature males well before they did so with the young males in any of the groups, but it is probable that this was forced copulation rather than the result of pheromone action on the female.

Role of DDT-hydroxylation in Resistance

To prove the rate of enzymatic detoxication in resistance, a direct correlation between the degree of insecticide resistance with the enzyme system concentration within the insect must be shown. Thus, in the housefly, DDT * is readily converted to DDE by cell-free preparations and the resistance appears to be proportional to the DDT-dehydrochlorinase activity[1]. DDT is also metabolized to a 'Kelthane'-like material by a microsomal enzyme system, in several insect species, including *Triatoma infestans*[2,3]. However, no significant data are available on the possible relation of DDT-hydroxylation to resistance. Correlation between the level of enzymatic detoxication and resistance can be shown by *in vivo* specific inhibition or stimulation of the enzymatic process, resulting in decreased or increased resistance, respectively. In this respect, it is known that SKF 525–A and other compounds, such as iproniazid, block microsomal hydroxylation reactions[4], while 3-methylcholanthrene acts like an activator[5]. By using this last approach, it has been possible to show that the degree of tolerance to DDT by nymph *T. infestans* can be modified by the foregoing inhibitors and activators, suggesting that DDT-hydroxylation plays indeed a part in resistance.

T. infestans third instar larvæ, which are fairly tolerant to DDT[6], kept under the conditions of Dinamarca *et al.*[3] were used throughout. To groups of 15 insects, 10 μl. of an acetone solution containing 30 μg SKF 525–A or 3-methylcholanthrene were topically applied to the ventral abdominal region of the insects by means of a micropipette. Iproniazid phosphate in aqueous solution (75 μg/3·3 μl.) was intracœlomatically injected at the dose of 75 μg per specimen. After treatment for 24 h, the insects were topically intoxicated with 200 μg DDT in acetone solution per specimen[3], and the survival determined thereafter for 72 h. In order to follow the production of internal polar DDT-metabolites[3], ring-labelled DDT-^{14}C (5,000 c.p.m./μg) was used. The latter was applied at the dose of 4·0 μg per specimen in 10 μl. acetone[3]. After 24, 48 and 72 h of the application of the DDT-^{14}C, the insects were rinsed three times in acetone to eliminate any external insecticide, homogenized in chloroform and extracted according to Dinamarca *et al.*[3]. The chloroform extracts were fractionated in an activated alumina column by the procedure of Sternburg *et al.*[7]. The carbon tetrachloride eluate, containing unchanged DDT and DDE[3], and the combined benzene and acetone eluates which correspond to the polar metabolites, were concentrated to a known volume and an aliquot taken for measuring the radioactivity. Proper functioning of the alumina columns was checked by paper chromatography of the carbon tetrachloride and benzene–acetone eluates[3].

---

* Abbreviations: DDT, 2,2,-*bis*-(*p*-chlorophenyl)-1,1,1-trichloroethane; DDE, 2,2-*bis*-(*p*-chlorophenyl)-1,1-dichloroethylene; 'Kelthane', 2,2-*bis*-(*p*-chlorophenyl)-1,1 1-trichloroethanol; SKF 525–A, β-diethyl-aminoethyl-diphenylpropyl acetate; iproniazid; 2-isopropyl-1-isonicotinoyl hydrazine.

Control groups were treated only with either SKF 525–A, iproniazid, 3-methylcholanthrene, acetone, or injected with water. At the doses used, SKF 525–A and 3-methylcholanthrene proved to be non-toxic, while iproniazid alone produced a small mortality of 8 per cent 96 h after injection. Topically applied acetone or injected water was without effect on the insects during the entire experimental period. Ring-labelled DDT-^{14}C was synthesized in the laboratory[3]. SKF 525–A was a gift from Dr. James R. Gillette. The rest of the reagents used were of commercial sources. Radioactivity was measured as described elsewhere[3].

Fig. 1 shows the effect of SKF 525–A, iproniazid, and 3-methylcholanthrene on the toxicity of DDT to *T. infestans* nymphs. It is evident that SKF 525–A and iproniazid potentiate the effects of DDT. At 72 h, DDT alone produced a 58 per cent mortality, while with SKF 525–A and iproniazid, the mortalities were 81 and 89 per cent, respectively. On the other hand, the mortality of DDT-intoxicated insects decreased to 46 per cent by the action of 3-methylcholanthrene, indicating a certain degree of antagonism between DDT- and 3-methylcholanthrene.

When experiments were conducted with DDT-^{14}C, it was found that iproniazid and SKF 525–A substantially decreased the rate of production of polar metabolites, while 3-methylcholanthrene increased their production (Table 1). The latter effect, although fairly small, was consistently found in several experiments.

Our results indicate a negative correlation between the mortality and the rate of production of DDT–polar metabolites. When the latter were decreased, for example, by the effect of SKF 525–A at 72 h, to about 52 per cent, as compared with control insects, mortality increased about 23 per cent. On the other hand, when DDT–polar metabolites were increased to 11 per cent of the controls by the action of 3-methylcholanthrene at 72 h, mortality decreased in 12 per cent. The reported observations would apparently contradict those of Hewlett *et al.*, showing no effect of SKF 525–A on the toxicity of DDT to *Aliphitobius laevigatus*[8]. However, there is no evidence that DDT is metabolized to hydroxylated compounds by this insect, as occurs in *T. infestans*[3]. Further supporting our work, Terriere[9] has recently observed that DDT-resistant houseflies contain microsomal tissue of greater hydroxylating capacity than those isolated from normal insects. Whether the effect of SKF 525–A, iproniazid and 3-methylcholanthrene reflect a depression or an acceleration, respectively, of the rate of specific protein biosynthesis at the microsomal level, or simply an inhibition or activation of microsomal enzymes, is now under investigation. On the basis of this work, it is concluded that DDT-metabolization via hydroxylation plays a part in resistance.

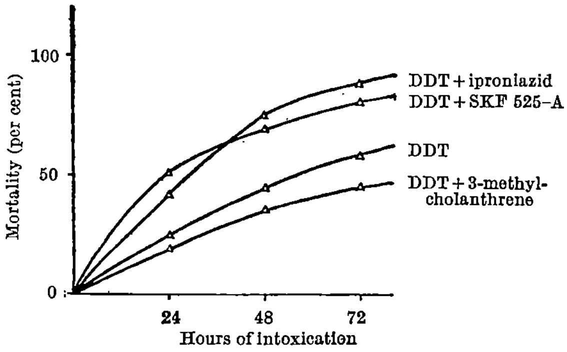

Fig. 1. Effect of iproniazid, SKF 525–A and 3-methylcholanthrene on the mortality of DDT-intoxicated nymph *T. infestans*. The values are the average results of 15 experiments

Table 1. Effect of Iproniazid, SKF 525–A, and 3-Methylcholanthrene on the *in vivo* Production of DDT-^{14}C Internal Polar Metabolites by Nymph *T. infestans*

The values correspond to the average of 5 experiments

Compound	Metabolites production (% of DDT controls		
	24 h	48 h	72 h
Iproniazid	60	78	75
SKF 525–A	52	41	52
3-Methylcholanthrene	124	115	111

Sex Attractant of Male Scorpion Flies

It is well known that in mecopteran flies of the family Panorpidae courtship and mating behaviour fall into a distinctive pattern[1]. In the case of the Bittacidae, the recorded observations[2–4], although suggestive, have been insufficient to reveal clear-cut feeding and mating patterns

Harpobittacus nigriceps (Selys) is a very important predator of the cinnabar moth (*Callimorpha* (*Tyria*) *jacobaeae* L.) which was introduced into Australia for the control of ragwort (*Senecio jacobaea* L.). Observations carried out in the Gippsland area of Victoria, where *Callimorpha* was released, and later in the Australian Capital Territory on the closely similar *Harpobittacus australis* (Klug), brought to light an extraordinarily interesting pattern of courtship behaviour in which the emission of a sex attractant by the male is combined with the presentation to the female of a nuptial meal. Part of the interest of these observations stems from the fact that the production of a 'female lure' has been very seldom reported in the Insecta.

Both species of *Harpobittacus* search for the soft-bodied insects on which they prey by flying slowly upward along the stems of herbage with their powerful raptorial hind legs outstretched. The long prehensile tarsi vibrate rapidly while they systematically explore the surfaces of the plants. Anything soft or moving is captured instantly by the hind tarsi, which coil around the prey. Once the victim is held securely, the predator seeks out a suitable plant on which to settle and feed. As soon as the biting mouthparts penetrate the integument of the prey, an apparent paralysis sets in, suggesting the presence of some toxic constituent in the saliva. Feeding is usually completed in 1–2 min.

It is significant that the females of *H. nigriceps* and *H. australis* were never observed hunting, capturing o

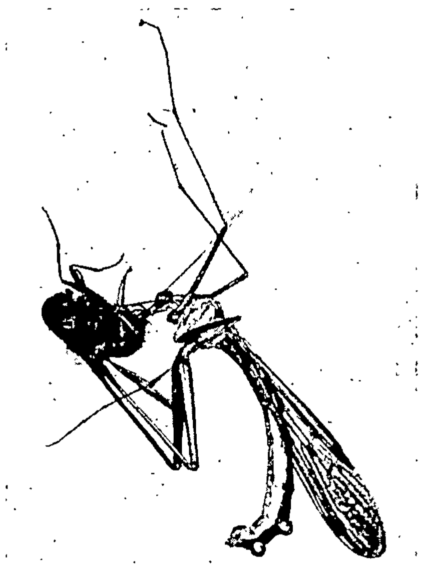

Fig. 1. A male *H. australis* in its female-luring position with vesicles everted (× *c.* 1·5)

killing prey in the field. When the male *Harpobittacus* is holding its prey and starts feeding, two reddish-brown vesicles are everted on the abdomen between tergites 6–7 and 7–8 (Fig. 1); and these can be observed to expand and contract in a slow rhythmic motion. These abdominal vesicles discharge a scent, best described as musty, which is perceivable by the human nose. In the field it acts as a sex pheromone[5] which attracts the females to the vicinity of the male. Females down-wind of a male with prey in its clutches have been repeatedly observed to move unerringly in his direction.

As soon as the female is within reach of the male, the latter retracts its vesicles (presumably ceasing immediately to emit scent) and brings the prey to its mouthparts. The female makes efforts to get hold of the prey, but is prevented in this by the hind legs of the male. During the somewhat agitated proceedings, the abdomen of the male seeks out the tip of that of the female and manipulates it until impregnation commences. Once in copula, the male voluntarily passes the prey with its hind legs over to the female, which eagerly accepts this nuptial food offering.

This courtship and mating pattern, which is virtually identical in *H. nigriceps* and *H. australis*, will be described in greater detail elsewhere. The composition of the *Harpobittacus* sex pheromone is being investigated by colleagues in this Division. A preliminary examination has been carried out of the scent-producing vesicles. They do not appear to have any associated scent reservoirs; and they seem to consist of a specialized intertergal membrane, the cells of which presumably discharge their secretion directly on to the membrane surface (Dr. D. F. Waterhouse, personal communication).

MICROBIOLOGY

Immuno-clinical Classification of *Staphylococcus pyogenes aureus*

Experimental pyelonephritis in animals and clinical pyelonephritis in man have been under serious investigation at Columbia Presbyterian Medical Center for the past decade. We have been publishing and presenting scientific exhibits at various time-intervals. In 1958, an immunological approach for the possible diagnosis of pyelonephritis in man was undertaken because, bacteriuria being intermittent, the urine culture in such patients was often negative, and no abnormal urinary and radiological changes were demonstrable, particularly early during the course of this disease.

Pyelonephritis is a very common condition. Among the autopsy cases at Columbia–Presbyterian Medical Center in 1940, 11·1 per cent of the kidneys microscopically showed evidence of pyelonephritis, while in 1960 it rose to 26·1 per cent[1]. The results of agar-gel immunological investigations were first reported from our laboratories in the form of a scientific exhibit at the annual meeting of the American Medical Association and American Urological Association in 1960, and a brief reference was made to this technique by us in 1962[2].

While evaluating the results of the agar-gel precipitation bands in patients suffering from chronic pyelonephritis, we observed a very significant fact concerning antibodies to *Staphylococcus pyogenes aureus*. A tabulation showed that some strains of *Staphylococci* reacted uniformly with all patients' sera, while a second group very rarely reacted with such sera, and an intermediate or third group reacted with 5–30 per cent of sera. Having observed this immunological phenomenon, we undertook a survey in 1960 to test as many clinical strains of *Staphylococcus* as possible against the sera we obtained from patients suspected of clinical pyelonephritis.

Every patient suspected of pyelonephritis is routinely examined by the house physician, a urine specimen is collected for culture and 10 ml. blood obtained for serological investigations.

The following eight cultures are being routinely used as antigens in these investigations because they are commonly involved in upper urinary tract infections: *Proteus columbiensis* (*P. rettgeri*, *P. mirabilis*, *P. vulgaris*), *P. morganii*, *K. pneumoniae*, *A. aerogenes*, *E. coli*, *P. aeruginosa*, *enterococcus* and *Staphylococcus pyogenes aureus*. These pathogens are grown for 18 h on Difco brain heart agar in Roux bottles; they are then lysed by sonic oscillation in a Raytheon oscillator *DF* 101, 250 W, 10 kc/s, 115 V and 60 c/s, for 30 min.

One per cent 'Ion agar' (Oxoid) in normal saline is heated to dissolve, and 1 : 10,000 merthiolate is added. Four and a half ml. of melted agar is put on a standard (25 × 75 mm) microscope slide. After the agar has solidified, eight peripheral wells are bored with core borer No. 2, and two centre wells with No. 3. The serum of the patient is put in the centre well, while eight antigens are put in the peripheral wells. The slides are kept at room temperature in a closed plastic freezer box containing moist cotton balls or beakers of water to prevent drying. The readings are taken at the end of 24 and 48 h. The same procedure is carried on using antigens obtained from various *Staphylococcus pyogenes aureus* obtained from surgical and urological patients.

So far 840 sera from patients suffering from chronic pyelonephritis have been tested since 1958, using our eight standard antigens. This observation in pyelonephritis will be reported separately. During this period 221 clinical strains of *Staphylococcus pyogenes aureus* have been tested against 288 sera obtained from cases of chronic pyelonephritis.

A tabulation of these *Staphylococci* showed that 81 *Staphylococcus* or 36·7 per cent gave agar-gel reactions with more than 50 per cent of sera tested. These have been named Group I. Twenty-six of this group are tentatively placed in Sub-group I*a*, and they account for 11·1 per cent of *Staphylococcus*. Sub-group I*a* reacts with almost 100 per cent of sera tested. Forty-four or 19·9 per cent of *Staphylococcus* reacted with less than 5 per cent of these sera, some showing no reaction whatever. These have been named Group III. In the intermediate

Table 1. IMMUNO-CLINICAL CLASSIFICATION OF *Staphylococcus* OBTAINED FROM 221 PATIENTS

Group	No. of *Staphylococcus*	Per cent
I (I*a* included)	81	36·7
I*a*—sub-group	26	11·1
II	96	43·4
III	44	19·9

Group II there were 96 *Staphylococcus* which reacted with 5–30 per cent of sera tested, and they accounted for 43·4 per cent of the pathogens.

We do not know the significance of this observation. We are now preparing typing sera in rabbits with these four types of *Staphylococcus*, so that we shall be able to type all clinical and laboratory strains of this pathogen. Moreover, we shall try to correlate these types with phage 80/81, mutation in relation to chemotherapeutic agents, urease production, coagulase reaction, toxin production, virulence, epidemiology etc. . . . and the possible relationship to superinfection under the impact of chemotherapy with antibiotics.

A brief review of the literature shows that some interesting observations have been reported in this field. Staphylococcal typing by agglutination and agglutinin absorption methods has been in use for some time since first reported by Blair in 1939 (ref. 3). In 1960, Haukenes and Oeding[4] described agglutinins *m* and *n*, and attempted to correlate agar-gel bands with agglutination reaction. Jensen[5] typed 161 *Staphylococci* against sera from 951 donors by agar gel method, and described eight antigens, namely, *A*, *B*, *C*, *D*, *E*, *F*, *G* and *H*; up to six were present in a single strain. Antigen *A* was found in all pathogenic *Staphylococci*, and corresponding antibody found in all normal sera. The sera from infected patients contained more antibodies of the other types than sera from healthy patients. Haukenes, Losnegard and Oeding[6] tested acid and alcohol extracts of *Staphylococci* and found Jensen antigen *A* to be chemically and immunologically distinct from carbohydrate *A* which was identified in all pathogenic *Staphylococci* by Julianelle and Wieghard[7]. Lofkquist and Sjoquist[8] proved the identity of Jensen's *A* and Verwey's type specific protein. Oeding and Haukenes[9] compared agar-gel precipitin bands and agglutinin. Of 9 specific factors used in agglutinin typing, three formed bands in agar gel, namely, *n*, *h* and *i*. Polysaccharide *A* of pathogenic *Staphylococcus* is known to be ribitol terchoic acid mucopeptide.

These observations lead us to believe that there are certain patterns or trends in the nature of the highly mutagenic pathogen, *Staphylococcus*, which have become a great nuisance in the two decades of antibiotic therapy. Apparently, within the species of *Staphylococcus pyogenes aureus*, strain or race variation may be responsible for the erratic behaviour of this organism.

Investigations in Europe and ours in the United States have been carried out independently. Complete and adequate knowledge of these three or four types of *Staphylococcus pyogenes aureus* may prove to be of clinical and epidemiological importance, similar to Lancefield's contribution to the classification of *Streptococcus*.

CYTOLOGY

Effects of Tannic Acid and Mercury on Huma Erythrocytes

INVESTIGATIONS have been carried out in this laborator on the effect of various substances on the permeability erythrocytes to non-electrolytes in an attempt to elucida the problem of the relationship between the molecul anatomy of the cell membrane and the movement molecules across it. The effect of these same substanc on other characteristics of erythrocytes, including hæm lytic volume, initial volume and fragility, may also gi information which will contribute to a possible solutic of the basic problem. The present report includes da obtained from an investigation of the effect of tannic ac and mercury on these parameters.

Human blood was obtained by venipuncture an citrated. It was refrigerated no more than 24 h befo being washed three times in solution *A* (phosphat buffered, *p*H 7·1, isotonic sodium chloride). For examin tion of initial volumes, 1 ml. of packed cells obtaine following the third washing was added to 10 ml. solution *A* and another 1 ml. of packed cells was added t 10 ml. of solution *A* containing mercuric chloride tannic acid. After 10 min, both solutions were centr fuged at approximately 2,000*g* for 10 min. The supe natant fluid was discarded and the packed cells we used for cell counts[2] and hæmatocrit measurements From these results the initial volume of the cells in th presence and absence of the two substances could b calculated. The highest concentration of mercur chloride used in these experiments was 8×10^{-5} M an of tannic acid $3 \cdot 5 \times 10^{-4}$ per cent.

The method of Hoffman *et al.*[4] was used to measure th hæmolytic volume ($\bar{V}_h$). Stock suspensions of contr and experimental cells were prepared as above. Aliquo of the packed cells were added to different volumes water as described by these authors. The experiment cells were added to water containing mercury or tann acid. In some experiments the value for 100 per cen hæmolysis in these solutions was slightly different fro the control reading. Calculations using both dat however, led to the same conclusions. The highe concentrations used in the cell suspensions in the experiments were $2 \cdot 7 \times 10^{-6}$ M mercuric chloride an $3 \cdot 5 \times 10^{-4}$ per cent tannic acid. The highest concentr tions used in the water were $2 \cdot 0 \times 10^{-6}$ M mercur chloride and $4 \cdot 6 \times 10^{-4}$ per cent tannic acid.

Since previous experiments with 'Triton *X*-100' (ref. had demonstrated that with fragility measurements th concentration of the substance in the salt solutions wa effective while the concentration in the stock solutio made no difference, aliquots of packed cells were adde directly to solutions of sodium chloride of differen osmotic pressures. The highest concentrations used i these experiments were $5 \cdot 9 \times 10^{-6}$ M mercuric chlorid and $2 \cdot 9 \times 10^{-3}$ per cent tannic acid.

A stock solution of tannic acid was prepared freshl each day for all types of experiments. A stock solution o 10^{-3} M mercuric chloride was kept in a 'Desicote'-covere flask. Dilutions of this solution were prepared freshl each day in a desicote-covered flask. All measurement were made at room temperature (20° ± 2° C).

Table 1. EFFECT OF TANNIC ACID AND MERCURIC CHLORIDE ON $\bar{V}_h$ O HUMAN ERYTHROCYTES

Substance	Concentration	No. of observations	$\bar{V}_h$	
Control		127	1·50	
Tannic acid	$3 \cdot 5 \times 10^{-4}$ %	127	1·23	8
Control		27	1·52	
$HgCl_2$	$1 \cdot 0 \times 10^{-6}$ M	24	1·45	1·
Control		70	1·41	
$HgCl_2$	$2 \cdot 0 \times 10^{-6}$ M	69	1·40	0·

Quickfit® leads the world with interchangeable laboratory glassware

From Manchester to Mandalay; from London Town to Leningrad, laboratories of every type are served by QUICKFIT glassware.

Once you take QUICKFIT products into your confidence you too will reflect on their distinct advantages—the sheer quality of the glass, the clever design, the precision ground connections and the remarkable finish.

Take a look at QUICKFIT — clearly it leads the world.

ZEISS

STEREO MICROSCOPE

This microscope incorporates automatic drum-change magnification which gives a range from 4× to 100× without the need to re-focus on altering magnification. The fixed working distance is 4″. Accessories are available for transmitted light and photo-micrographic work. Ideally suitable for the chemist and metallurgist in all forms of research work where simple and rapid operation is essential.

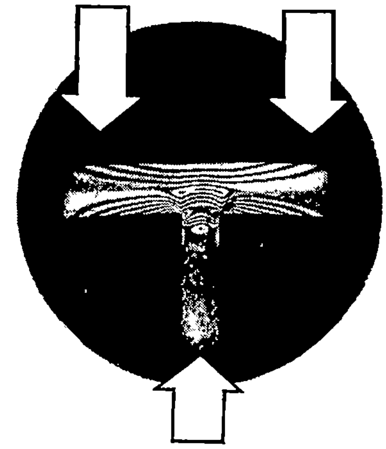
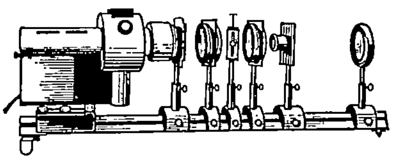
REVEALING THE EFFECTS OF

STRESS



IMPORTANT APPLICATIONS OF SPINDLER & HOYER OPTICAL BENCHES



Beam of light from carbon arc lamp is gathered in optical condensers, transmitted through polarizing screen, specimen, analysing screen and objective, which projects it on viewing screen. Spindler & Hoyer optical benches feature an automatic feeding device to move carbons uniformly through the lamp and eliminate adjustment. A wide range of sliding carriages and other accessories makes them extremely versatile.

(2) TEACHING

When specimens of plastic or special glass are fitted to a Spindler & Hoyer optical bench and subjected to stress, an image showing the effects is projected for observation. It may be filmed or photographed as a record. The instrument provides lecturers with a particularly graphic means of illustrating the principles of mechanics at work.

Industrial applications are numerous—Spindler & Hoyer optical benches are valued as time and money-saving equipment in many leading laboratories. For example, they are used to test glass and plastic mixes and product designs before manufacture, and to investigate the effects of stress on engineering projects at the technical design stage. For full details, please contact the sole U.K. distributors,

GREY OF NORWICH

Tel: Norwich 23696 & 26819

Both tannic acid and mercuric chloride increased the fragility of these cells slightly. To determine whether or not any of the differences are statistically significant an analysis was made of 44 control values and 65 observations in each of the most concentrated solutions of tannic acid and mercuric chloride. The values in 0·45 per cent sodium chloride were used since the greatest differences were observed in this solution. Using the Student *t*-test, the difference between the cells in the presence of mercury and the controls is significant at the 1 per cent level, and between tannic acid and the controls at the 0·1 per cent level. Neither of these substances produced a significantly different value for the initial volume.

The results of the investigation of the effect of these two substances on $\bar{V}_h$ are summarized in Table 1. It can be seen that high concentrations of tannic acid decrease the hæmolytic volume significantly. Mercury, however, in the concentrations used had no statistically significant effect on this parameter.

Comparing the present results with those previously reported on the effect of 'Triton' (ref. 5), it can be seen that none of these three substances has a marked effect on the initial volume. 'Triton' decreases, while mercury and tannic acid increase, the fragility of these cells. Mercury has no effect, tannic acid decreases and 'Triton' increases the hæmolytic volume. These observations can readily be reconciled with the suggestions previously made that each of these substances is acting on the membrane in a different manner.

Laser in Cytology

The article by Lang *et al.*[1] suggests that the ruby crystal laser, without mode control, is incapable of producing small areas of tissue destruction, and also that the triocular microscope is not usable. In this laboratory we have been using a ruby crystal laser and a triocular microscope as a routine instrument in biological investigation. The laser, originally designed for ophthalmological coagulation[2], has been modified to be easily connected to the microscope. In numerous experiments we have achieved areas of tissue destruction of $< 2\mu$ diameter, and Fig. 1 shows the effect of the pulsed ruby crystal laser beam on a gametophyte cell of the fern *Osmunda cinnamomea* L. It is worth remarking that we have investigated, theoretically, the temperature distribution in material irradiated by a focused laser beam in the system presented by the retina–choroid interface[3]. We are at present conducting a series of experiments on the volume/temperature relationships of laser irradiation in the case of homogeneous media and have shown, conclusively, the possibility of producing tissue destruction confined to the nucleus of a single cell.

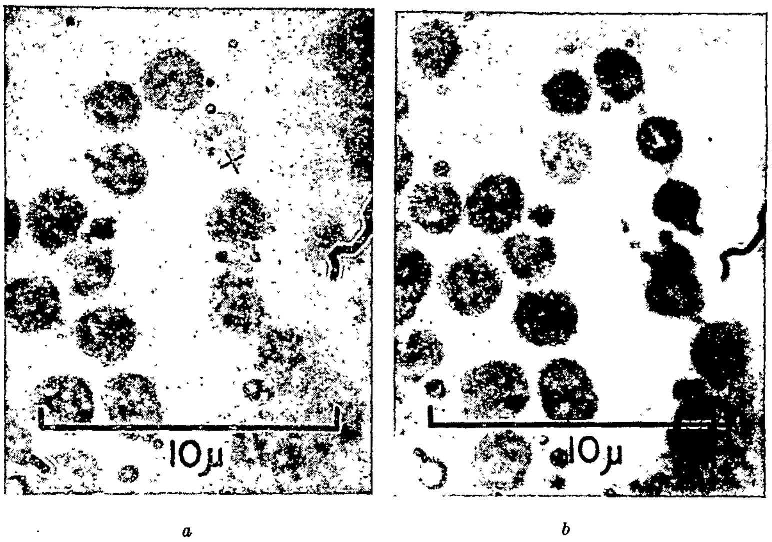

Fig. 1. Effect of a ruby laser beam burst on a living gametophyte cell of *Osmunda cinnamomea* L. (*a*), Before laser beam: the cross marks the point on the chloroplast at which the beam was aimed; (*b*), after a single laser beam burst of approximately 10 m joule into the triocular microscope

VIROLOGY

Effect of Urea on A_2 Influenza Virus

Although many investigations have been reported concerning the action of concentrated urea solutions on plant viruses, relatively few papers discussing the reaction of this reagent with animal viruses have been published.

Cooper[1] has recently described, in some detail, the action of urea solutions on poliovirus. He found that 7·2 M urea initially induced slight surface changes in poliovirus particles and these changes were followed by rupture of the particle. Loss of infectivity and release of RNA were associated with this rupture.

The effect of urea on the hæmagglutinin of influenza virus has been reported by Scott and Lauffer[2], who investigated the action of urea on the thermal stability of hæmagglutinin. Buckland and Tyrrell[3] have recently briefly recorded the response of influenza A_2 virus hæmagglutinin to urea solutions of varying concentration.

In the present work, the effect of concentrated urea solutions on a number of properties of influenza A_2 virus has been investigated. Purified preparations of *A*/Sing./1/57 were prepared by adsorption of virus from infected

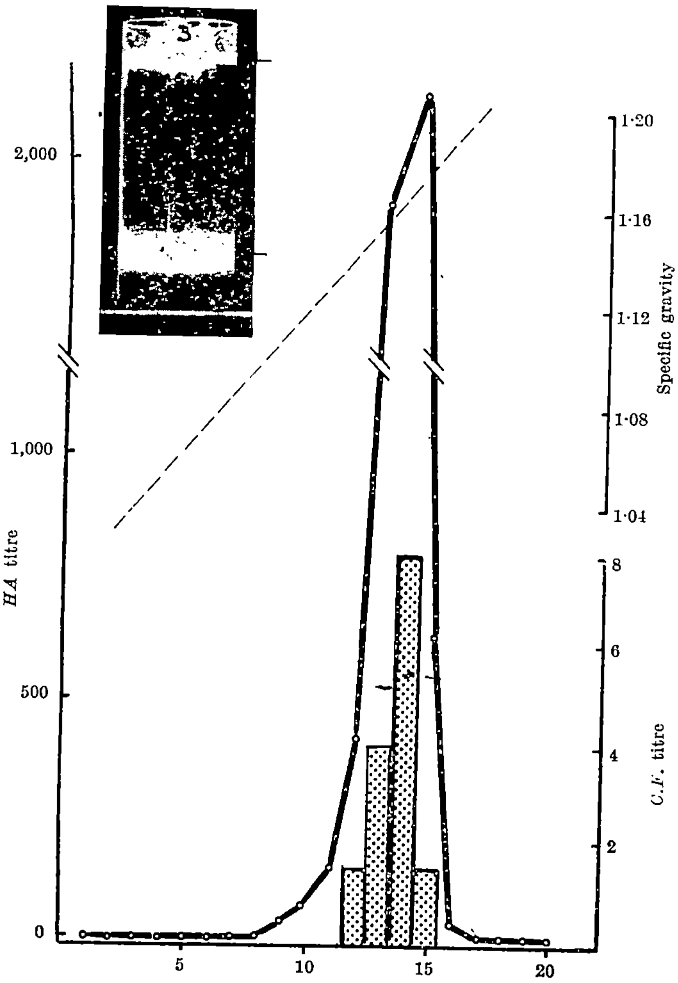

Fig. 1. Control virus. Distribution of light scattering material, hæmagglutinin (*HA*) and complement-fixing antigen (*C.F.*) after centrifugation on a potassium tartrate density gradient. ○, *HA* titre; – – –, specific gravity; stippling, *V* complement-fixing antigen

allantoic fluid on to human red blood cells followed by elution and passage of the eluate through a calcium phosphate column[4]. The virus was further concentrated by centrifugation yielding virus concentrates with hæmagglutinin titres of 1·5–2·0 × 10^5. Urea solutions were freshly prepared by dissolving urea, without heating, in 0·15 M sodium chloride containing 0·01 M phosphate buffer *p*H 7·0. Such solutions were free of cyanate[5,6]. Virus concentrates were treated with urea in the following manner: 0·1 ml. of concentrate and 0·9 ml. of 8 M urea, at the appropriate temperature, were mixed and the reaction allowed to proceed for the selected time. 6·0 ml. of chilled phosphate buffered saline was then added and the mixture transferred to a refrigerator. Control preparations were made by substituting phosphate buffered saline for the urea solution in the above procedure.

Table 1 shows the effect on the hæmagglutinin and the complement fixing antigens of exposure to 7·2 M urea, for 1 min at 0° C. The hæmagglutinin titre is unchanged when measured with guinea pig red blood cells but i reduced when measured with fowl red blood cells. Th *V* complement-fixing antigen is unaffected by the treatment, but in contrast there has been a marked increase in the titre of *S* complement-fixing antigen. Other experiments have shown that no change occurs in the neuraminidase activity of the virus following urea treatment under these conditions.

Table 1. TREATMENT OF A_2 INFLUENZA VIRUS WITH 7·2 M UREA FOR 1 MIN AT 0° C

	Hæmagglutinin* titre		Complement fixing† antigen titre	
	Fowl cells	Guinea pig cells	*S*	*V*
Control	2,560	2,560	<1	24
Urea treated	960	2,560	12	24

* 0·5 ml. volumes of serial, double dilutions were mixed with an equal volume of 0·5 per cent red blood cells and results were read after settling for 1 h at room temperature.

† Determined by the method of Belyavin (ref. 7) but using a single serum dilution.

To explore the foregoing changes in more detail, 4·0 ml aliquots of the control and urea-treated preparations were placed on potassium tartrato density gradient columns contained in 3 in. × 1 in. lusteroid tubes[8,9]. The tubes were then centrifuged in an *SW* 25.1 rotor (Spinco model *L* ultracentrifuge) for 90 min at 20,000 r.p.m. After centrifugation, the distribution of light-scattering material was recorded photographically. The contents of the tube were then displaced by the introduction of 45 per cent potassium tartrate solution into the bottom of the tube and 1·4 ml. fractions were collected from the top through a modified cap. Fractions were tested for hæmagglutinin using fowl red blood cells and, after overnight dialysis against phosphate buffered saline, for *V* and *S* complement-fixing antigen.

The results of the foregoing experiment are shown in Fig. 1, representing the control material, and Fig. 2, representing the urea-treated virus. A comparison of these figures reveals that there has been little change in the sedimentation behaviour of light-scattering material following treatment with urea under the conditions described. Furthermore, the distribution of hæmagglutinin

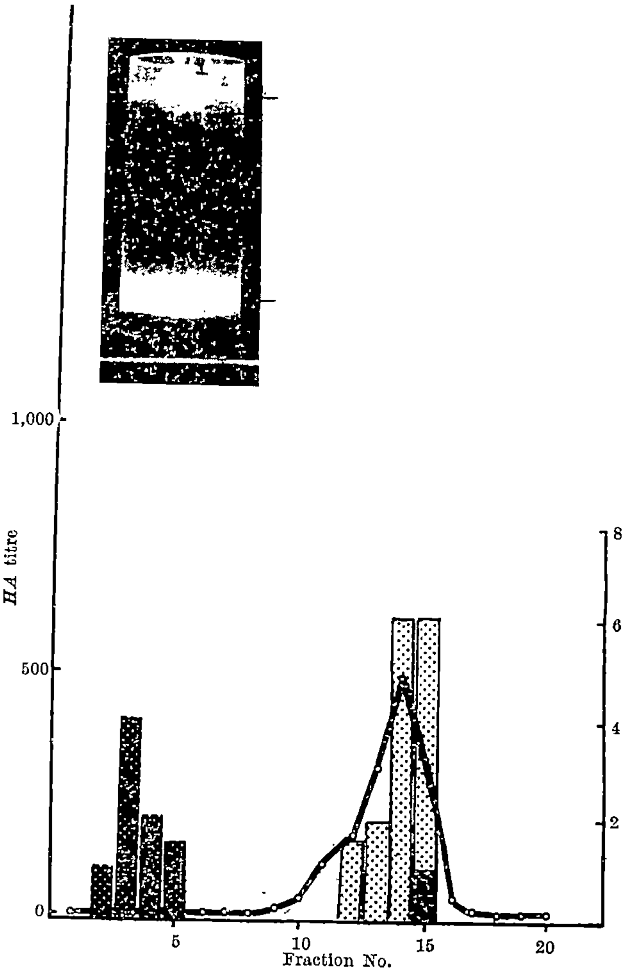

Fig. 2. Urea-treated virus (7·2 M urea for 1 min at 0° C). Distribution of light scattering material, hæmagglutinin (*HA*) and complement fixing antigen (*C.F.*) after centrifugation on a potassium tartrate density gradient. ○, *HA* titre; light stippling, *V* complement-fixing antigen; dark stippling, *S* complement-fixing antigen

s remained unchanged while the change in the dis-bution of *V* complement-fixing antigen is slight. wever, Fig. 2 shows quite clearly that the bulk of the complement-fixing antigen revealed by urea treatment liments much more slowly than either hæmagglutinin *V* antigen.

Brief treatment of A_2 influenza virus with urea thus pears to release *S* complement fixing antigen from the rus particle and in this respect resembles the action of ler on influenza virus described by Hoyle[10].

Extension of this work to the examination of the effect influenza virus of prolonged exposure to urea at higher mperatures has confirmed the rapid release of *S* com-ement-fixing antigen but has revealed marked additional anges in the hæmagglutinin and *V* complement fixing tigen of A_2 influenza virus[11].

I thank Prof. G. Belyavin for his advice. I also thank e Wellcome Trust and the Fleming Memorial Fund for e purchase of equipment used in this investigation. his work was carried out while I was on leave from the stitute of Pathology, Royal Alexandra Hospital for ildren, Camperdown, New South Wales.

GENETICS

Palatinose Element of the Receptor of the Melezitose Locus in *Saccharomyces*

THE receptor[1,2] of the melezitose (MZ) gene-system omprises at least five 'elements' corresponding to five -glucosidic inductors of the enzyme melezitase, an -glucosidase capable of splitting the five different -glucosidic inductors of MZ, namely, turanose, maltose, ucrose, α-methyl-glucoside and melezitose[3,4]. The otipotent allele, which responds adaptively to all five ubstrates, is designated MZ^{TMSGZ} (abbreviated to TMSGZ). artially recessive alleles, for example, TMSGz, TMSgz, Msgz, Tmsgz, and the totally recessive allele, tmsgz, ere obtained by ultra-violet irradiation[5]. (The small etters indicate specific inabilities of cultures to respond daptively to the corresponding substrates.) The multiple lleles are inferred, on the receptor-hypothesis[1,2], to eflect mutations (heritable changes in folding) of the roteinaceous receptor, a component of the gene con-rolling the capacity to respond to different inductors. t is of special interest to know if the synthetic α-glucoside, alatinose (α-glucosido-6-fructofuranose), can act as a ubstrate and an inductor of this particular enzyme. Emeis[6] has already shown that *Saccharomyces* cultures arry genes controlling the fermentation of palatinose, ut since there are other genes which split α-glucosides and fructofuranosides), and since he did not have genetic-lly identified MZ cultures with which to make specific ests, further analysis was necessary to implicate MZ. The totipotent TMSGZ cultures of the Lindegren Breeding Stock are able to ferment palatinose after 48 h, but specific artial mutants, for example, TMsgz and recessive tmsgz ultures, do not ferment palatinose when tested on EMB-gar and by the Durham tube technique (remained negative for five days)[7]. The fact that the TMSGZ cultures fermented palatinose suggested that palatinose might be one of the substrates (and possibly an inductor) by which the different alleles of the MZ locus may be distinguished from each other.

Melezitase induced in the palatinose-negative, partial mutant TMSgz, *B*4799 (the glucose-grown cells which ferment turanose, maltose, and sucrose after a lag period but which are unable to utilize palatinose, α-methyl-glucoside, melezitose or raffinose), hydrolysed palatinose. The culture was grown on glucose, yeast-extract, peptone nutrient broth for 24 h under aerobic conditions. The cells were adapted to maltose, collected, washed and tested for fermentation[8] of turanose, maltose, sucrose, α-methyl-glucoside, melezitose, palatinose, raffinose and glucose. In control experiments with unadapted cells in which melezitase had not been induced the same

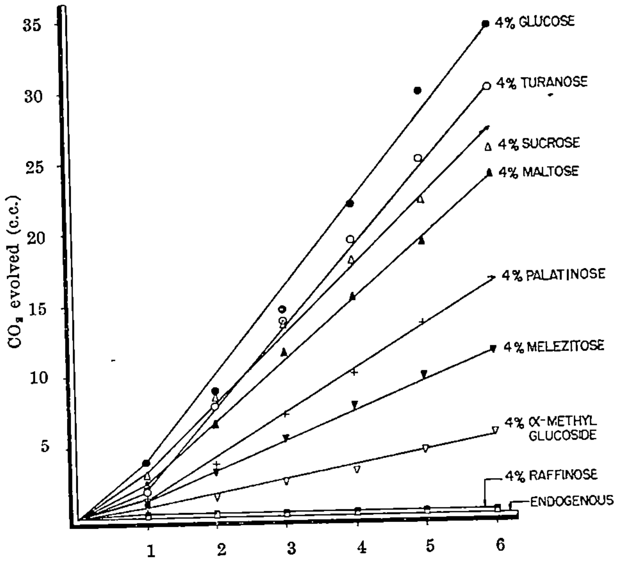

Fig. 1. Culture *B*4799 (TMSgz '*PA*') was grown in 2 per cent glucose nutrient broth for 24 h, adapted to 1 per cent maltose nutrient broth for 12 h and tested for CO_2 production on glucose, palatinose, turanose, maltose, sucrose, α-methyl-glucoside, melezitose and raffinose by the syringe gasometer (1·4 × 10^9 cells in 4 ml. of *p*H 4·5 phosphate buffer at 30° C)

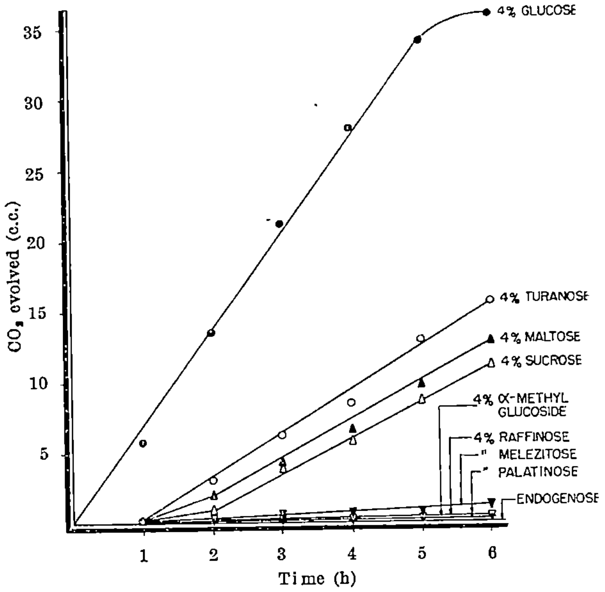

Fig. 2. Culture *B*4799 (TMSgz '*PA*') was grown in 2 per cent glucose nutrient broth for 24 h, then in 1 per cent glucose nutrient broth for 12 h and tested for CO_2 production on glucose, palatinose, turanose, maltose, sucrose, α-methyl-glucoside, melezitose and raffinose by the syringe gasometer (1·4 × 10^9 cells in 4 ml. of *p*H 4·5 phosphate buffer at 30° C)

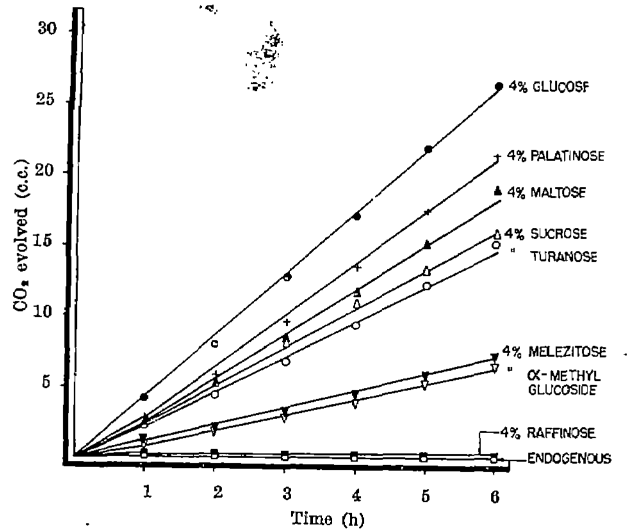

Fig. 3. Culture No. *D*1008Z (TMSGZ '*PA*') was grown in 2 per cent glucose nutrient broth for 24 h, adapted in 1 per cent palatinose nutrient broth for 12 h and tested for CO₂ production on glucose, palatinose, raffinose, turanose, maltose, sucrose, α-methyl-glucoside and melezitose by the syringe gasometer (1·0 × 10⁹ in 4 ml. of *p*H 4·5 phosphate buffer at 30° C)

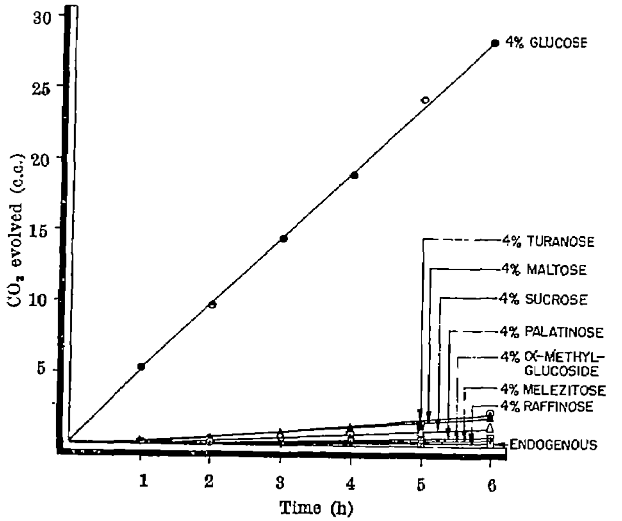

Fig. 4. Culture No. *D*1008Z (TMSGZ '*PA*') was grown in 2 per cent glucose nutrient broth for 24 h, then in 1 per cent glucose nutrient broth for 12 h and tested for CO₂ production on glucose, palatinose, turanose, maltose, sucrose, α-methyl-glucoside, melezitose and raffinose by the syringe gasometer (1·0 × 10⁹ cells in 4 ml. of *p*H 4·5 phosphate buffer at 30° C)

procedure was used (Figs. 1 and 2). The maltose-adapted cells of the TMSgz mutant immediately fermented palatinose and the other five substrates, although the different sugars were fermented at different rates. The unadapted cells were completely unable to utilize raffinose, indicating the absence of β-fructo-furanosidase[9]. These results indicate that the enzyme, melezitase, induced by maltose (in the palatinose-negative culture) is capable of hydrolysing palatinose and the other five substrates.

Similar experiments were performed using the palatinose-fermenting totipotent culture No. *D*1008Z (TMSGZ) (Figs. 3 and 4). Palatinose-adapted cells of TMSGZ fermented turanose, maltose, sucrose, α-methyl-glucoside, melezitose and palatinose, but glucose-grown cells did not ferment any of the six substrates without a lag period. These results indicate that palatinose can induce a melezitase which hydrolyses palatinose as well as the other five α-glucosides, and that another element (the palatinose element, *P*) is presumably a component of the MZ receptor.

Two palatinose-fermenting, totipotent, TMSGZ, single ascospore cultures, derived from the same ascus, were each mated to a recessive tmsgz culture which was capable of fermenting palatinose, and no recombinat were observed between the capacity to ferment palati and the capacity to ferment the other five substr among 23 tetrads from these hybrids. The close lin supports the view that the palatinose element is a c ponent of MZ.

A partial mutant (TMsgz) No. 14 *uv* (which had obtained by ultra-violet irradiation of a palatin fermenting, totipotent, TMSGZ culture, No. *D*10 fermented turanose and maltose but not palatin sucrose, α-methyl-glucoside or melezitose. The re suggests that the putative '*P*' element (along with elements '*S*', '*G*' and '*Z*') had been inactivated by ul violet irradiation. It is unlikely that ultra-violet irr ation would have simultaneously injured two sepa genes ('*MZ*' and '*PA*') in a single cell if one were to ass that '*PA*' was an independent gene rather than 'element' of the *MZ* receptor. Furthermore, when injury of the ultra-violet mutant was back-muta by exposure to melezitose, totipotent back mutants w obtained which had regained the ability to ferm palatinose along with recovery of the ability to ferm sucrose, α-methyl-glucoside and melezitose. Th abilities (once regained) remained tightly linked in s sequent genetical analysis.

We thank Dr. H. Hirschmüller, director of the Be Institute for Sugar Technology, for a supply of palatin We also thank Messrs. J. K. Bhattacharjee and Tom M. Yau for their assistance.

PSYCHOLOGY

Apparent Size of Holes felt with the Tongue

It is often said that holes, such as dental cavities, fe much larger to the tongue than they appear to the oth senses. This was tested by comparing the apparent si of holes when felt with the tongue and with the finge using the psychophysical method of constant stimuli.

Six research students in psychology, aged 22–30 yea acted as subjects. The subject closed his eyes and pa pated with his tongue a hole accurately reamed in t centre of a 2-in. square of 1/8-in. thick 'Paxolin', whi he held to his lips with his left hand. At the same tin he ran his right index finger round a circular row graduated holes and selected that which felt the san apparent size as the tongue hole. These graduated hol were arranged in steps of 1/64 in., from 1/16 in. up 1/2 in., and were bored in a metal annulus: they we the drill-holding holes in a Dormer drill holder.

Four standard holes were presented to the tongue, diameters 1/8, 1/4, 3/8 and 7/16 in. Each hole was pr sented eight times, in randomized order, and the dri stand felt by the finger was rotated through a rando angle after each trial, to counteract position habits. T

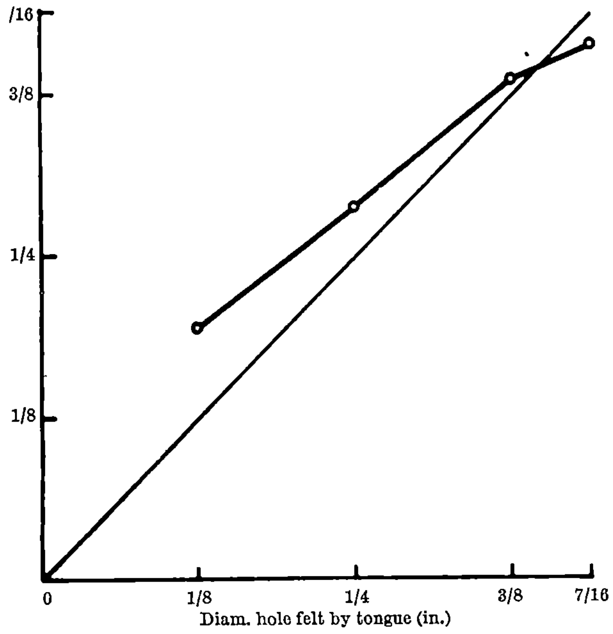

Fig. 1

.bject was allowed to see the finger holes on the drill and before the experiment, but not during it. No .bject saw the tongue holes at any time.

Results are shown in Fig. 1. Each point represents the ean of six subjects, with eight trials per condition. The e of unit slope (45°) indicates no illusion, where the ctual space of the tongue would be congruent with the ctual space of the finger. It will be seen that there is large illusion of just more than 50 per cent for the 8-in. hole, a smaller illusion (15 per cent) for the 1/4-in. le, but no appreciable illusion on the 3/8- and 7/16-in. les. The line which best fits these points by the method least squares is: $y = 0{\cdot}718x + 0{\cdot}106$.

The equations for the individual subjects are: $y =$ 616x + 0·097; $y = 0{\cdot}067x + 0{\cdot}152$; $y = 0{\cdot}768x +$ 089; $y = 0{\cdot}828x + 0{\cdot}117$; $y = 0{\cdot}450x + 0{\cdot}151$; $y =$ 005x + 0·034. A t-test shows that the slope of the dividual subjects' lines is significantly less than unity $< 0{\cdot}05$), and that they intercept the y axis at a value nificantly above zero ($P < 0{\cdot}01$).

So a size illusion is found when the tongue feels 1/8- d 1/4-in. holes, but not when it feels 3/8- and 7/16-in. les.

Alcohol Dehydrogenase Activity and Previous Ethanol Consumption in Mice

PREVIOUS investigations[1,2] have shown marked strain fferences in ethanol preference of mice, and a correlation tween strain means for alcohol preference and for liver cohol dehydrogenase (ADH) activity has been described[3]. urther investigation of this association between ADH d preference is needed to clarify the causal relationships, owever.

Available techniques require that alcohol preference sting precede ADH assay. Thus, if any increase in easured ADH occurs as a result of substrate ingestion, urious correlations would automatically arise from dividual differences in ethanol intake during the eference testing period. Dajani, Danielski and Orten[4] have described such enzyme alteration subsequent to ethanol ingestion in Sprague–Dawley rats, and Figueroa and Klotz[5] have shown an increase with later decrease in ADH activity in Sprague–Dawley rats forced to consume ethanol. Studies on the relationship of ethanol ingestion to ADH in mice should provide data of comparative interest as well as providing information of methodological importance for a planned series of researches on gene-enzyme relationships in ethanol preference of mice. The present investigations are concerned with two strains that differ extensively in the traits of interest: *C57BL/Crgl* mice with high alcohol preference and high ADH activity, and *DBA/2Crgl* mice with strong alcohol avoidance and low ADH activity.

ADH activity was measured in liver homogenates by the rate of reduction of diphosphopyridine nucleotide (DPN) under standard conditions. The procedure used has been described in detail previously[3].

The condition of 'forced' alcohol consumption was imposed simply by providing the animal with only a 10 per cent ethanol solution as a liquid source. Variations of three basic conditions were employed in different studies. The basic conditions were: (*a*) a period of forced alcohol consumption terminating at the time of enzyme assay; (*b*) a period of forced alcohol consumption with a period of forced water consumption intervening before enzyme assay; (*c*) a control condition in which the animal never was provided with alcohol.

Male animals from the *C57BL* and *DBA/2* inbred mouse strains were used. Descriptions of the origin and some of the characteristics of these strains have been given by Jay[6].

Investigations 1 and 2 were designed to determine if the amount of alcohol ingested in the two-week test routinely used for measuring preference could increase measured ADH activity. Forcing animals to consume alcohol solution exclusively for this period of time should provide an estimate of the maximum increase that could be expected in a choice situation.

The effect of forced alcohol consumption, of course, might reasonably be expected to differ in strains which differ markedly in baseline ADH activity and in alcohol preference. In investigation 1, ADH activity was measured in control and experimental (forced alcohol consumption) animals from both the *C57BL* and *DBA/2* strains. All animals were 57 ± 3 days old when killed for ADH assay. The experimental animals had been forced to drink alcohol for either 15 or 16 days prior to killing. Investigation 2 was a partial replication of investigation 1, differing from it in these respects: (*a*) Animals were 77–84 days old when killed for ADH assay; (*b*) the experimental animals had been on a forced alcohol condition for 14 days prior to killing for ADH assay.

Investigations 3 and 4 were undertaken to determine if the alteration in ADH activity observed in investigations 1 and 2 would persist in the absence of ethanol. In *C57BL* and *DBA/2* mice, animals forced to consume alcohol for 3 weeks (3*FAC* group) and control animals were compared to animals which had been forced to consume alcohol for 2 weeks and had then been returned to control conditions (water only available) for 1 week immediately preceding death (2–1 group). Age at time of death was 90 ± 3 days for all groups. The 2–1 group and the 3*FAC* group were thus introduced to the forced alcohol consumption condition at the same age.

Investigation 4 compared 2*FAC* and control animals to animals forced to consume alcohol for 2 weeks and then returned to control conditions for 3 weeks prior to death (2–3 group). Age at time of death was 90 ± 3 days. The 2–3 group was thus introduced to the forced alcohol consumption condition three weeks earlier than the 2*FAC* group.

The results are summarized in Table 1 and Fig. 1. Three measures used to express ADH activity present the same general picture of an increase in liver ADH activity with

Table 1. Means of Measures of Investigations 1–4

Strain	Condition	Study	*N*	Weights Body (g)	Liver (g)	Liver ÷ body	Micromoles ethanol oxidized/min per g liver	Entire liver	Entire liver per g body-wt.

* The experimental animals of investigation 1 are approximately 2*FAC*, and are shown as such in this Table and in Fig. 1.

forced substrate ingestion and a reduction of ADH activity with abstinence. The relation is most regular and consistent when ADH activity is expressed in terms of liver weight as in Fig. 1.

These results confirm earlier reports[3,7] that liver ADH activity in *C57BL* mice exceeds that of the *DBA/2* mice.

The increment in ADH activity for the experimental (forced alcohol consumption) conditions appears to be of approximately the same magnitude in the two strains. This, of course, results in a greater percentage increase for the *DBA/2* animals. Because of the aversion of the *DBA/2* animals to alcohol, the total ingested by the forced alcohol consumption groups is less than that of the corresponding *C57BL* groups. For example, in investigation 1 the mean fluid consumption per gram body-weight for the control groups was 0·176 ml. and 0·184 ml. for the *C57BL* and *DBA/2* strains, respectively. The mean fluid intake/g body-wt. for the forced alcohol consumption groups was 0·196 ml. and 0·128 ml. for the *C57BL* and *DBA/2* strains respectively. Under ostensibly the same conditions, then, the *C57BL* animals drank more ethanol although water requirements, as measured by intake in the control condition, are similar in the two strains. Therefore, a detailed analysis of the relative ADH activity increase in the two strains would require controlled substrate administration or correction for consumption differential.

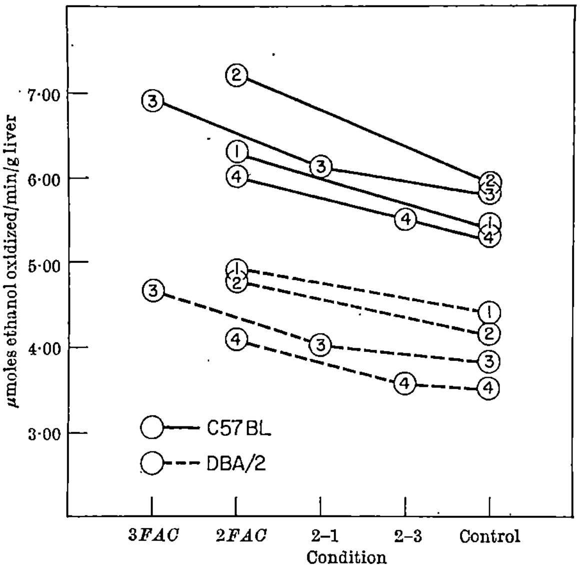

Fig. 1. Alcohol dehydrogenase activity under different conditions. Numbers in circles designate different studies

The results demonstrate that measured ADH activit increases as a function of ingestion of the substrate, an that activity declines toward control values when th substrate is withdrawn. It appears that the absence o ethanol ingestion for three weeks permits almost complet return to baseline values, and, by extrapolation, a period o four weeks or more should constitute an adequate interva in further research on the relationship of ADH to alcoho preference. It is not known, of course, whether th increase in ADH activity represents release of inhibition actual *de novo* synthesis of the enzyme, or some othe process. Nor has it been demonstrated that an increas of this relatively small percentage magnitude has detectable effect upon ethanol metabolism.

The liver weight results, taken primarily for purpose of correcting the ADH activity data for differences i organ size, are of interest *per se*. The larger livers of th *C57BL* animals may simply reflect their greater bod size. The ratio of liver weight to body-weight does no differ between the strains (Table 1). In both investigations (3 and 4) which include a group forced to consum and then to abstain, that group has liver weight in exces of either their control group or the forced alcohol consump tion group. This is true for both strains. Whatever th process responsible for this phenomenon, it appears to b either accelerated by, or initiated by, the cessation c ethanol consumption. Further investigation of thi phenomenon might be of value to the examination of live pathologies associated with alcohol consumption b human beings.

This work was supported by grant *G*–14221 from th U.S. National Science Foundation and also receive support from the U.S. Atomic Energy Commission.

FORTHCOMING EVENTS

Tuesday, August 18—Friday, August 21

ity of Cambridge, School of Clinical Research and Post- Medical Teaching (in the Lecture Theatre of the Department omy, Tennis Court Road, Cambridge), at 9.15 a.m. daily—Symposium rent Research in Leukaemia".

APPOINTMENTS VACANT

pplications are invited for the following appointments on or before dates mentioned:

xperimental Officer in Electrical Engineering in the Faculty of nce, to be responsible for the development and operation of high vacuum electronic equipment—The Registrar, The University, Manchester, 13 gust 22).

esearch Assistant (with a degree) in the Department of Geology, arry out cartographical work and evaluate echo traces for an investigation he submarine topography of the northern North Sea—The Registrar, University, Liverpool 3, quoting Ref. CV/260 (August 22).

esearch Assistants (2) (science graduates) in the Laboratories of Rheumatism Research Centre, to take part in studies of the experi- ntal immuno-pathology and ultrastructure of synovial and other connec- tissues—The Registrar, The University, Manchester, 13 (August 22).

esearch Associates in the following subjects: biology, organic chemis- , mechanical engineering, civil engineering and physics—The Principal, tingham and District Technical College, Burton Street, Nottingham gust 22).

emonstrator (graduate) in Agriculture (Animal Production) in the artment of Agriculture, to assist with experiments and for general duties he University farms—The Registrar, The University, Leeds, 2 (August 24).

ibrarian (with a scientific background, preferably with a pass degree or ivalent, and proficient in German)—The Secretary, John Innes Institute, fordbury, Hertford (August 24).

ssistant Lecturer in Pure Mathematics—The Registrar, The Univer- , Sheffield (August 26).

ssistant Lecturer (with special interests in stratigraphy and sedi- ntation) in the Department of Geology—The Registrar, The Univer- , Manchester 13 (August 27).

xperimental Officer (with a university degree or Higher National tificate, and preferably some knowledge of digital electronics and data dling systems) in the Department of Computer Science, to have ponsibilities for special purpose systems connected to the Atlas computing chine and to assist with the development of new equipment—The Regis- r, University of Manchester, Manchester, 13 (August 27).

raduate Assistant (Administrative) in the Department of Educa- n—The Registrar, The University, Manchester, 13 (August 28).

ecturer (graduate in veterinary science or honours graduate within the ulty of Science, and preferably with postgraduate qualifications and a earch background) in Animal Husbandry at the University of Queens- d, Australia—The Secretary, Association of Commonwealth Universities anch Office), Marlborough House, Pall Mall, London, S.W.1 (London and isbane, August 28).

enior Lecturer (veterinary graduate with postgraduate qualifications honours graduate with a science degree majoring in anatomy and physiol- or biochemistry) in Animal Husbandry (Meat Production) at the iversity of Queensland—The Secretary, Association of Commonwealth iversities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 ndon and Brisbane, August 28).

enior Lecturer (with a higher degree in biochemistry and considerable ching and/or research experience in this field) in Biochemistry at the iversity of Queensland, Australia—The Secretary, Association of Common- alth Universities (Branch Office), Marlborough House, Pall Mall, London, V.1 (London and Brisbane, August 28).

echnician (with Ordinary National Certificate in Chemistry or equivalent alification) to assist with research in the Botany Department—Prof. J. Carr, Department of Botany, The Queen's University, Belfast, Northern land (August 28).

Assistant Lecturer (with medical qualifications registrable in the ited Kingdom) in Anatomy—The Registrar, The University, Manchester, (August 31).

Biochemist or Chemist (Scientific Officer grade) to work in a team studying ion of organo-phosphorus insecticides—The Secretary, Rothamsted perimental Station, Harpenden, Hertfordshire (August 31).

hair of Chemical Engineering at Newcastle University College, The iversity of New South Wales—The Warden, Newcastle University College, ghe's Hill, N.S.W., Australia; and The Agent General for New South ales, 56–57 Strand, London, W.C.2 (August 31).

Chair of Psychology at Newcastle University College, The University New South Wales—The Warden, Newcastle University College, Tighe's ll, N.S.W., Australia; and The Agent General for New South Wales, –57 Strand, London, W.C.2 (August 31).

Lecturer in Theoretical Physics in St. Salvator's College—The Secre- ry, University of St. Andrews, College Gate, St. Andrews, Scotland ugust 31).

Post-Doctoral Research Fellow (with experience in adsorption studies in mass spectrometry) for the spectroscopic investigation of molecules sorbed on surfaces—Prof. N. Sheppard, School of Chemical Sciences, iversity of East Anglia, Wilberforce Road, Norwich, NOR 77H (August 31).

Research Assistant (with a degree in zoology and an interest in fresh- ter biology or ecology) for work on the profundal fauna of lakes—The gistrar, The University, Liverpool 3, quoting Ref. CV/269 (August 31).

Senior Assistant Librarian or Librarian (chartered librarian, and for e higher grade an appropriate university degree) to be employed principally cataloguing and classification duties—The Academic Registrar, Lough- rough College of Technology, Loughborough, Leicestershire, quoting ef. 21/G (August 31).

Research Assistant (with a pass degree in one of the natural sciences) assist in an investigation of unidentified phenolic constituents of plants— e Secretary, Low Temperature Research Station, Downing Street, Cam- idge, quoting Vacancy 64/23 (September 1).

Statistician (Assistant Lecturer or Lecturer) to assist and initiate in- stigations in the Department of Social Medicine and consult with her members of the School and Hospital—Dr. H. W. Holland, Department Social Medicine, St. Thomas's Hospital, London, S.E.1 (September 1).

Post-Doctoral Research Assistant (preferably with an interest in the plication of physico-chemical methods to biochemical problems) in the epartment of Biochemistry, to investigate interaction phenomena in hæmoglobin reactions—Dr. S. Ainsworth, Department of Biochemistry, The University, Sheffield, 10 (September 2).

Administrative Assistant (graduate of a British university and preferably experience of university administration) in the Institute of Education—The Registrar, The University, Liverpool 3, quoting Ref. CV/268 (September 5).

Senior Lecturer (medically qualified man or woman) in the Department of Public Health and Social Medicine—The Secretary, The University, Edinburgh (September 5).

Research Fellow (with a Ph.D. or equivalent postgraduate experience in experimental geophysics, and preferably experience in the maintenance or development of electronic equipment) in Seismology in the Department of Astronomy—The Secretary, The University, Edinburgh (September 7).

Principal Scientific Officer (Senior Zoologist, Research) (with a good honours degree in zoology, considerable postgraduate ecological research experience, and preferably a knowledge of Scottish fauna) at the Edinburgh Headquarters of the Nature Conservancy—The Nature Conservancy (E), 19 Belgrave Square, London, S.W.1 (September 10).

Senior Lecturers; Lecturers; and Assistant Lecturers in Geography, in the following fields of specialization: cartography, climatology, geomorphology, and economic geography, at University College of Cape Coast, Ghana—The Assistant Registrar (Overseas), University College of Cape Coast, 15 Gordon Square, London, W.C.1 (September 11).

Research Assistant (with an honours degree in botany or agricultural botany) to investigate the effects of storage conditions on the life span of crop seeds—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge (September 12).

Lecturer in Physiology in the Institute of Obstetrics and Gynæcology at Queen Charlotte's and Chelsea Hospitals and at the Institute of Basic Medical Sciences—The Secretary, Institute of Obstetrics and Gynæcology, Chelsea Hospital for Women, Dovehouse Street, London, S.W.3 (September 14).

Fellow, Senior Research Fellow or Research Fellow in a Unit of Cell Biology and Immunology within the Department of Experimental Pathology, The John Curton School of Medical Research, Institute of Advanced Studies, Australian National University, for studies on acquired immunity and on mechanisms involved in the responses and interactions of cells—Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, September 15).

Assistant Director of Research in the Mathematical Laboratory—The Secretary of the Appointments Committee of the Faculty of Mathematics, Arts School, The University, Bene't Street, Cambridge (September 16).

Lecturer (preferably with special competence in X-ray diffraction and crystallography and/or electron diffraction) in Physics at the University of Cape Town—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1; and The Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town, South Africa (September 25).

Senior Lecturer or Lecturer in the Department of Mathematics, University of Cape Town—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1; and The Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town, South Africa (September 25).

Reader in Microbial Genetics—The Registrar, University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne, 2 (September 26).

Chair of Botany at the University of Hong Kong—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Hong Kong and London, September 30).

Chair of Operational Research in the Department of Engineering Production—The Registrar, University of Birmingham, Birmingham 15 (September 30).

Lecturer or Assistant Lecturer in Food Chemistry in the Department of Nutrition in the School of Home Science of the University of Otago, Dunedin, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, September 30).

Senior Lecturer or Lecturer (with experience in teaching and research) in Physical Chemistry at the Australian National University—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, September 30).

Abstractor (science graduate interested in plant pathology and mycology and information handling, and preferably a reading knowledge of one or more foreign languages)—The Director, Commonwealth Mycological Institute, Ferry Lane, Kew, Surrey.

Agricultural Chemist (with a degree in chemistry or agricultural chemistry, and preferably postgraduate experience in agricultural chemistry with specific reference to soil and plant analysis and the design and evaluation of field trials) in Northern Rhodesia, to supervise routine chemical analysis for agricultural purposes, and to undertake development or modification of analytical methods, as governed by crop response to suit the needs of agriculture in Northern Rhodesia—Appointments Officer, Department of Technical Co-operation, Room 301, Eland House, Stag Place, London, S.W.1, quoting Ref. RC/213/132/010.

Alfred Capper Pass Chair of Organic Chemistry—The Registrar, The University, Senate House, Bristol 2.

C.E.G.B. Research Fellow in High Temperature Electrochemistry—The Secretary and Registrar, The University, Southampton.

C.E.G.B. Research Student in High Temperature Electrochemistry—Prof. G. J. Hills, The University, Southampton.

Chair of Zoology—The Registrar, The University, Senate House, Bristol 2.

Laboratory Technician in the Department of Veterinary Medicine, to work on research and diagnosis in connexion with animal diseases—The Professor of Veterinary Medicine, University of Bristol, School of Veterinary Science, Langford, near Bristol.

Physicist (with a good honours degree) to initiate and undertake basic research in machining processes—The Secretary, Production Engineering Research Association, Melton Mowbray, Leicestershire.

Research Assistant (honours graduate in zoology, biochemistry, or genetics) in Genetics, to participate in investigations into the physiological genetics of melanotic tumours in the fruit-fly *Drosophila*—The Registrar, The University, Sheffield.

Research Assistant (with an honours degree in physics, biology, medicine or a related subject, and preferably with a broad range of scientific interests) in the Electron Microscopy Unit—Dr. G. Eaves, Department of Experimental Pathology and Cancer Research, School of Medicine, The University, Leeds, 2.

Research Fellow (either medically qualified person with some interest in computers, or a graduate with a knowledge of computer methods wishing to work on medical problems) in Electronic Digital Computer Methods, to undertake studies on the development and application of automatic data processing of medical information—Dr. W. W. Holland, Department of Social Medicine, St. Thomas's Hospital, London, S.E.1.

RESEARCH FELLOW (preferably with a Ph.D. degree and research experience in a subject related to this work) IN THE INSTITUTE OF SOUND AND VIBRATION RESEARCH, for work on the application of high damping alloys in engineering to alleviate noise and vibration—The Secretary and Registrar, The University, Southampton.

VIROLOGIST (preferably with previous experience in microbiology) for tissue culture work in a diagnostic virus laboratory—Consultant in Laboratory Medicine, Belvedere Hospital, Glasgow, E.1.

REAPPRAISAL OF TREASURY CONTROL

ONE of the recommendations of the Plowden Committee on Representational Services Overseas (*Nature*, 202, 1039; 1964. 203, 439; 1964) arose out of that Committee's concern that the unified Service proposed in its Report should be in a position to respond quickly and in time to changing requirements. For this the Plowden Committee held that flexibility in the control and deployment of man-power was essential. This is generally true also of scientific and technical man-power, but the Plowden Committee was more particularly concerned that there should be a sufficient margin of man-power to cover the time necessarily spent in travel, training, home leave and sick leave. The Committee received convincing evidence that lack of such an adequate reserve of man-power had seriously impeded the effective deployment of the present Foreign and Commonwealth Services and had led to overstrain.

It was considered vital that this situation should be remedied and the Committee was satisfied that a margin of the order of 10 per cent was reasonable. It recommended accordingly that the authorized man-power of the new Diplomatic Service should be calculated to include such a reserve, though it recognized that it would have to be built up gradually: emphasis was placed on the fact that such a reserve should not be squandered by the creation of new operational posts. Firm management would be required to ensure that this reserve was held and used for the purposes intended, and such management would also ensure that, as requirements change and new commitments are accepted, old commitments which have ceased to be worth while should be dropped. Further, it believed that a reasonable man-power ceiling such as is proposed accentuates the departmental sense of responsibility and encourages both real economy and morale.

The cost of providing and maintaining such a reserve of man-power was put at £750,000 a year, but the Government was not prepared to accept the recommendation in full. Instead, it was agreed that the position should be reviewed again when a margin of 7·5 per cent had been achieved, probably in about two years time. There would then be a careful reappraisal as a basis for deciding whether or not it was necessary to go so far as the 10 per cent recommended. The main basis of the Committee's argument was unchallenged, and the decision taken accords with what the Plowden Committee itself recognized as being practical.

In spite of this, however, this recommendation of the Plowden Committee has now been rejected outright by the Estimates Committee, without seriously examining the evidence presented to the Plowden Committee and questioning the fact that the Diplomatic Service might, under the present arrangements, be understaffed. In its fifth report for the Session 1963–64, *Treasury Control of Establishments**, the Estimates Committee, refusing to discuss any such considerations of overstrain and possible undermanning, refuses peremptorily to consider the proposal of the Plowden Committee on the ground that it endangers the present system of Treasury control of the Civil Service. The purpose which that control is intended to preserve is ignored, and accordingly the vital question whether such control effectively serves the national interests is unasked. Control for control's sake is advocated nakedly and unashamed, and the present system of determining reserves for the Foreign Service should be retained, regardless of its proved defects.

There are two major reasons why this attitude of the Estimates Committee should not be allowed to pass unchallenged. First, such an attitude has the most serious implications for the association of scientists and technologists in the task of government, whether in the strictly scientific and technical sphere, or in that of administration. Inevitably, it must hinder scientific and technical work, leading to frustration and inefficiency and waste. It is also likely to discourage scientists and technologists from taking their fitting share in administration—a point on which considerable emphasis was placed in a recent Fabian Group pamphlet, *The Administrators: the Reform of the Civil Service* (*Nature*, 203, 555; 1964), as well as in the earlier Plowden Report, *Control of Public Expenditure*, issed in July 1961 (*Nature*, 192, 485; 1961).

The second reason is that the unenlightened and restrictive attitude which marks this Report from the Estimates Committee is detrimental to the valuable work which that Committee has done in the past and also to the public esteem of Parliament. It is no service to the effective control of public expenditure to refuse to consider the purposes which such expenditure is intended to service and subordinate the end to the means. There is already a large volume of criticism of the effectiveness of Parliament and suggestions for reform are being freely, if seldom convincingly, advanced. This is a vital element in arriving at an appropriate system for the public discussion of policy and for integrating advice and judgment in ministerial decisions. Solution will not be easier if the standing or prestige of Parliament is diminished by recommendations as ill-founded as that of the Estimates Committee in this matter. The report could well be the subject of some consideration by the Parliamentary and Scientific Committee, all the more in that there are other recommendations which are constructive and enlightened.

It should be noted that the Plowden Report on *Control of Public Expenditure* arose essentially out of a recommendation in an earlier report from the Select Committee on Estimates in 1958 on *Treasury Control of Expenditure* and the comment of the Treasury in a subsequent special report in the Session 1958–59. The recommendations of the Plowden Report led to certain changes in the internal organization of the Treasury in November 1962, designed to contribute more positively to good management throughout the Civil Service, and the present arrangements for Treasury Control are outlined in this latest Report from the Estimates Committee. The Report, however, is not limited to the methods by which the numbers and grades of personnel in departments are kept under scrutiny by the Treasury, but considers also the management functions of the Treasury, including recruitment and the introduction of computers. Moreover, the Report includes among the minutes of evidence a memorandum submitted by the Treasury on Treasury control of departmental establishments and the minutes of an interview with Sir Ronald Holroyd, which covers the experience of Imperial Chemical Industries, Ltd., in the recruitment and management of staff.

---

* Fifth Report from the Estimates Committee together with the minutes of the Evidence taken before Sub-Committee C and Appendixes, Session 1963–64—*Treasury Control of Establishments*. Pp. xxxvi+172. (London: H.M.S.O., 1964.) 12*s*. 6*d*. net.

Where the Estimates Committee has gone astray is clear early in the Report. The present system for controlling numbers and grading in the Civil Service is basically that established in 1949. The primary method is a twice-yearly review of man-power, at which the total ceiling of a department's non-industrial staff is fixed. Below this figure, departments can vary the numbers and grades of their staff in particular fields up to the level of their delegated authority, but the creation of senior posts and staff expenditure on any new function or any considerable expansion of an existing function requires Treasury approval. To ensure that complementing and grading standards are properly applied in departments, test checks are made by a team of staff inspectors from the Treasury.

The Estimates Committee agrees with the principles underlying the present system, though it makes certain recommendations. The April review of the man-power of Civil departments should be abolished and the Treasury should require departments to submit their October returns in regular sequence. The Treasury should establish an interdepartmental committee to review the existing arrangements for delegated authority with the view of raising the level throughout the Civil Service for the professional, scientific and technical classes, and for the general service classes also in departments where the establishment officer is of a rank lower than under-secretary. Establishments (Complementing) Division should make regular and systematic examinations of the staff of all Civil departments over a period of 3–5 years.

The Committee tried hard to induce Sir Laurence Helsby, Joint Permanent Secretary to the Treasury and head of the Home Civil Service, to commit himself to the Committee's view that the recommendation of the Plowden Report regarding the staffing of the Diplomatic Service would make it impossible for the Treasury to perform its primary duty, "to ensure that no more staff are employed than are needed; that posts are correctly graded by reference to duties; that suitable staff are assigned to the posts; and that consistent standards are maintained throughout the Service". However, it is obvious that Sir Laurence Helsby has an open mind on this matter. He pointed out, in fact, that the 10 per cent margin recommended by the Plowden Committee was not a full 10 per cent increase, though the existing margin which the Plowden Committee thought inadequate was not disclosed. Sir Laurence thought that it might not be necessary to exceed the 7·5 per cent margin adopted for the present, but preferred to reserve judgment until we had seen over the next two years what a modest increase in the existing reserve did to make for a greater flexibility. He gave no support to the idea that removal of Treasury scrutiny from this reserve violated the whole principle of Treasury control.

On the evidence of this report, the Estimates Committee's concern that one of the most important functions of the Treasury is to be the agent of the House of Commons and its committees in determining the amount of public expenditure and the means by which the House controls the size and pattern of the public service has blinded it to the real issues. It is irrelevant that other departments are, in general, satisfied with the present system. We are faced with a proved defect which the Estimates Committee will not really face, least of all the fact that the size of the Civil Service is ultimately determined by Government policy which increases or curtails the work to be done. So naïve a recommendation could scarcely have come from the Committee if its members had read Lord Bridges's recent book, *The Treasury* (*Nature*, 203, 555; 1964), particularly the chapter, "Treasury Staff Control: How it Works".

Even so, it is difficult to account for so futile a recommendation in a report characterized otherwise by much sound sense and insight, particularly when, as already noted, the recommendation could hinder the recruitment of scientific and technical staff with which the Estimates Committee was also concerned. The interdepartmental committee it recommends is intended partly as a contribution to the more effective use of such staff. However, the Committee's major recommendation in this field is that the Treasury should take positive steps to stimulate the recruitment of scientists by producing a better career structure within the Scientific Class and should encourage the transfer of members of the Scientific Class to the Administrative Class. Sir Laurence Helsby, in evidence, admitted that there was a considerable shortage of scientists in the Civil Service, while the Treasury memorandum referred to the difficulty of discerning and applying standards or objective criteria in the work of professional and scientific staff. This is a prime reason for seeking to increase the delegated authority in such classes.

Sir Laurence pointed out that in the recruitment of scientists the Treasury and the Civil Service Commission were already co-operating to the maximum extent. However, much of this recruitment was on a temporary basis and the research fellowships offered by the Commission had attracted some exceptional scientists who did not respond to establishment on a career basis. He agreed that the dividing line between the administrative and the scientific and professional classes might have been too rigid and hindered recruitment. Nevertheless, he did not think that the scientist was at a grave disadvantage. While they had been disappointed about the willingness of potential administrators to move from the scientific field into the administrative class, within the past three months a competition to that end had been more successful than any for some years and fifteen really promising administrators had been recruited from the scientific class.

It was at this point that Sir Ronald Holroyd's evidence was relevant. However, while the Estimates Committee does not consider that there should virtually be no boundary between administrative and specialist tasks, it wishes to encourage to the full the incorporation, so far as possible, of scientists into the management team of a department, provided recruitment for the purely scientific posts was fully maintained. The Estimates Committee considers that, in any event until recently, there has been too rigid a barrier between the administrative and scientific classes and that this should be relaxed. This is not of itself likely to contribute greatly towards making the Civil Service more attractive as a career to the younger scientists: other factors are probably much more important, and the interchange between the Civil Service and industry, with which the Estimates Committee was next concerned, could contribute something to the establishment of the atmosphere which is most likely to overcome the reluctance of a scientist to adopt the Civil Service as a career.

In spite of recommendations in the earlier Plowden Report and elsewhere, such interchange does not occur on any appreciable scale—though the Treasury was considering whether it would increase its initiative here. Sir Ronald Holroyd in his evidence referred to the need for people in the Civil Service who can speak the language of industry. Even though there was good agreement on this point, it is an open question whether this broadening of experience is best achieved by physical interchange of staff or by the exchange of experience and ideas. Sir Laurence had reservations as to how far the former had really benefited the Civil Servants who had enlarged their experience in this way, and very clearly there are considerable practical difficulties in arranging such interchange which do not apply, for example, to interchange with universities. Nevertheless, the Estimates Committee is satisfied that the more informed discussion and exchanges of ideas can occur the better for all concerned. The barrier between the Civil Service and industry is, indeed, gradually being broken down, but the Estimates Committee urges that the process should be accelerated as much as possible. The new syllabus at the Centre for Administrative Studies, which provides for visits to industrial concerns, is one example of increasing Treasury initiative in this field, and the Committee recommends that the Treasury should make every effort to increase the scope for interchange of knowledge and experience between the Civil Service and industry both at home and abroad.

For the rest, the Estimates Committee in this report considers at some length the management services of the Treasury, now organized under an Under-Secretary, responsible to the Third Secretary (Management). While it has no doubts as to the skill and efficiency of the Organization and Methods (General) Division, it questions whether this skill is fully utilized, partly through lack of control over departments which have their own organization and methods branch and partly through the limitations imposed by the Division's advisory role. The Committee thinks that the Treasury should require such departmental branches to submit a forward programme of their assignments, in which the Treasury should participate if it thought fit. It also recommends that the Division should carry out planned reviews of all the departments for which it had responsibility.

The role of the Organization and Methods (Machine) Division is also advisory, but it participates in any major mechanization scheme in the Civil Service, and in this sphere of machines the Treasury plays a much more central part. The Division has already, rightly, in the Committee's opinion, taken on itself immense responsibilities which it is believed to be fulfilling with care and skill. Contrary to some rather vocal criticism elsewhere, the Estimates Committee found the Civil Service at least as far advanced in this field as a commercial concern such as Imperial Chemical Industries, Ltd., without plunging recklessly into excessive expenditure without proper consideration. For this position the credit is given to the Treasury, and steps are also being taken to make all departments fully aware of the great potentials of mechanization. Welcoming the Treasury's initiative, the Committee also expresses the hope that still further steps will be taken to instil into all departments a proper appreciation of the immense potentialities of computers as a means of speedier and more efficient management.

The third of the management divisions, Management Services (General Division), has only operated since November 1962, and is responsible for investigating problems outside the strict field of organization and methods, and acting as an organ of the Treasury, to compare the practices of several departments. The Estimates Committee welcomes this wider opportunity but does not consider that the opportunity has yet been used. It recommends accordingly that the organization and functions of the Division should be reviewed to enable it to carry out a wider range of investigations which the Committee believes are of the highest importance.

Generally, the Committee holds the opinion that the greatly increased emphasis in the Treasury on management since November 1962 is to be welcomed and it hopes that the initiative will be maintained and strengthened. To a large extent, the impulse here comes from the Plowden Report on *Control of Public Expenditure*, but the Estimates Committee does not accept all the implications of that Report. It challenges, for example, the view which, it suggests, is implicit in that Report that the Treasury and the other departments are more or less equal partners, and that the work done by the complementing divisions is far less important than the political work to be done by the management divisions. Unhesitatingly, the Committee affirms the supremacy of the Treasury, at least to the extent of the right and duty to institute regular and thorough inspections of the departments.

The Plowden Committee maintained that there should be no interference with a department's responsibilities, and it can certainly be argued that regular inspection by the Treasury tends to undermine departmental responsibility. The Estimates Committee's anxiety to restore the supremacy of the Treasury, however, really stems from its desire to reassert the authority of the House of Commons. That much is plain from any reading of A. Hill and A. Whichelow's *What's Wrong with Parliament?* They point out that to-day control by the House of Commons of Government spending is now largely non-existent and only the Treasury can help. While Members are aware of this and are now more wary about the full financial implications of the policies they approve, they still cling to old procedural forms which no longer grip the matters they were designed to control.

Mr. Hill and Mr. Whichelow argue firmly that the influence and prestige of Parliament would be restored by use of a series of parliamentary special committees—as opposed to the Party committees which have developed since the Second World War—and they cite as an example the Select Committee on the Nationalized Industries. In this system, they suggest, the Estimates Committee would itself occupy an important place: its inhibition in respect of policy would be removed and its six sub-committees might form the basis of the new committees. The Public Accounts Committee would probably continue to function as at present, but if the Estimates Committee were no longer debarred from criticizing Government policy, the futilities in its present report would be unlikely to recur.

While there is some substance in the view that the weaknesses in the present Report arise out of out-dated procedures, more is involved than procedures. There is also the question of the function of the Treasury itself, and it is obvious that the Estimates Committee is poles asunder from the view put forward by the Fabian Group in the pamphlet mentioned earlier. The Fabian Group sees the functions of the Treasury as very different and does not regard it as good for the Civil Service that the department responsible for financial control should also be responsible for policy and management of personnel, since it is judge in its own cause: considerations of finance may take precedence over ideas of enlightened management. Whether in fact that happens seems a little doubtful on the evidence of the Estimates Committee's report, but the function of the Treasury as viewed by the Fabian Group should be considered in the light of its proposal to transfer to the Civil Service Commission the responsibility for personnel management and the structure of the Civil Service. For that, however, the pamphlet must be considered in greater detail, and all that can be added here is that, like the Estimates Committee itself and Mr. Hill and Mr. Whichelow in discussing the reform of Parliament, the Fabian Group is intensely concerned with the recruitment and use of scientists on an adequate scale and up to the highest levels.

THE INTERNATIONALE OF SCIENTISTS

The Dawn of a New Age

Reflections on Science and Human Affairs. By Eugene Rabinowitch. Pp. viii + 332. (Chicago and London: University of Chicago Press, 1963.) 6.95 dollars; 52*s*.

THIS book by the internationally known, respected and loved editor of the *Bulletin of the Atomic Scientists* contains his reflexions on human affairs extending over almost twenty-five years. He first presents his credentials as a prophet in two astonishingly accurate forecasts of the Second World War, written on September 1, 1939, and on May 5, 1941. After this it comes as less of a surprise that in his later essays, written at the time of the Korean war, of the Vietnam crisis, of the first *Sputnik* and of the Cuban crisis, he has displayed the same sound judgment; always confirmed, never contradicted by what has happened since then.

Eugene Rabinowitch was born in the U.S.S.R. and is now professor of biophysics at the University of Illinois. He has maintained friendly relations with a great number of Soviet scientists, without ever ceasing to be critical of their system. His essay on "Russian and Soviet Science" is a masterpiece of balanced judgment. In this, and in all his other essays collected in this volume, he pleads a realistic gospel of understanding and of patience, which is probably equally uncongenial to the average unsophisticated American with a somewhat fundamentalistic cast of mind, who can see nothing but diabolic wickedness in Communism, and to the fundamentalists among his fellow-scientists, who recommend conscientious objection, and who can see no hope short of "Banning the Bomb".

Rabinowitch is a Fabian of disarmament, who keeps his eye steadfastly on what is possible, without ever forgetting the final goal. The report to the Secretary of War, 1945, of which he was one of the chief authors, and which has become known as the Franck Report, and his speech for the President in 1954, are fine examples of his method of approaching influential non-scientists. If not even words of such wise moderation so closely argued from incontrovertible facts have an effect on politicians, then what use are words? Rabinowitch must have often asked himself this question, yet he has never despaired, and never given up his patient pleading. If, as is very likely, he and people like him have made even a small contribution to the tremendous fact that fifteen years after both sides came into possession of the atomic weapon not a single nuclear bomb was exploded in anger, this ought to be considered a rich reward for their patience.

The book contains thirty essays, grouped under the headings "Looking Ahead", "Taking Stock", "Talking with World Scientists", and "Heretical Thoughts". If anybody looks for really heretical thoughts, he will be disappointed. Rabinowitch offers plain common sense, and he scorns Bernard Shaw's trick of dishing up commonsense as a shocking paradox. It is somewhat regrettable, but in the nature of things, that out of his many pages of carefully balanced arguments, it will be scarcely possible to lift out even one epigram, which might take root in the common man's mind. He is a fluent and polished writer, eminently readable, yet sometimes I wish he had taken advice from 'Mad. Ad.'. But any serious reader, scientist or humanist, will find great enjoyment in reading his book.

D. GABOR

PHYSICIAN AND PHILOSOPHER

John Locke (1632–1704): Physician and Philosopher

A Medical Biography, with an Edition of the Medical Notes in his Journals. By Kenneth Dewhurst. Pp. xii + 331 + 11 plates. (London: The Wellcome Historical Medical Library, 1963.) 42*s*.

JOHN LOCKE'S abiding fame rests on his philosophy. He may be regarded as the founder of empiricism, which is the doctrine that all our knowledge (with the possible exception of logic and mathematics) is founded on experience. He was born in 1632, but did not publish the *Essay Concerning Human Understanding* until 1687. Six years (1687–1693) sufficed for this and his further works on *Toleration*, *Government* and *Education* to make him the most influential and perhaps the greatest of British philosophers. His teaching in his lifetime and after his death exerted a far-reaching political influence. The British Constitution was based on Locke's doctrines until some sixty years ago; with Montesquieu's additions they are part of the American Constitution; they had a determining influence for the French philosophers and the moderate reformers in the French Revolution and inspired the French Constitution in 1871[1].

So great is Locke's stature as a philosopher that it is often forgotten that he was also a scientist, and throughout the greater part of his life a practising physician, a writer of medical essays and of clinical reports and papers. The view may well be accepted that it was his interest in science and prolonged observation of disease that led him to reflect on human knowledge and to enunciate his views that this equally was based on experience.

When Locke died, his large store of manuscripts, notebooks and journals went to his cousin, Peter King, later Lord Chancellor. The seventh Lord King, in 1829, published an indifferent biography, entitled *Life and Letters of John Locke*, with a few extracts from the journals. The medical aspect of Locke's life was brought forward in Dr. John Brown's discursive essay, "Locke and Sydenham" (*Horae Subsecivae*, 1866). In 1876, H. R. Fox Bourne's reliable biography, the *Life of John Locke*, appeared in two volumes, which examined new material including some of Locke's medical writings. This led to the brief but admirable studies of two medical historians, Dr. E. T. Withington[2] and Sir William Osler[3], who both concluded that Locke was an experienced and skilful physician of sound judgment and advanced views. They surmised that he gave more time to his chosen profession than the manuscripts then disclosed. These beliefs were confirmed in 1948, when the Bodleian Library, with the aid of the Clarendon Press, purchased from the Earl of Lovelace (a descendant of the first Lord King) a large collection of Locke's unpublished papers including much material of medical interest.

Dr. K. Dewhurst, Wellcome Research Fellow in medicine, Corpus Christi College, Oxford, has sedulously studied and deciphered the medical papers in this new source of material and has written this scholarly medical biography of John Locke, which reveals the philosopher's attainments as scientist and physician. Included are a complete edition in English of the medical notes in Locke's journals and a biographical survey of his other medical writings.

John Locke, the son of a Somersetshire lawyer, in 1646 entered Westminster School under Dr. Busby. Among his school-fellows were Richard Lower, Walter Needham and John Mapletoft, future physicians. In 1652 he proceeded to Christ Church, Oxford, graduating B.A. in 1655 and M.A. in 1658. In 1659 he was elected to a senior studentship at Christ Church; in 1660 he became lecturer in Greek and in 1662 lecturer in rhetoric. Dr. Dewhurst notes that Locke kept a medical note-book and studied science and medicine from the beginning of his university career; and also that through his friend, Lower, he was early in touch with the precursors of the Royal Society, that group of experimental philosophers, including William Petty, Thomas Goddard, Ralph Bathurst, Christopher Wren, Thomas Willis, and Robert Hooke, who met in the rooms of John Wilkins, Warden of Wadham College. In 1660 Locke's friendship with Robert Boyle augmented his interest in medical chemistry or pharmacology; and he studied botany in the Oxford Botanic Garden and attended Willis's lectures on therapeutics. In 1665 he served as secretary to Sir Walter Vane's diplomatic mission to the Elector of Brandenburg. Returning to Oxford, he worked with his friend, Dr. David Thomas, at practical chemistry and in 1666 joined him in medical practice. Lord Clarendon, Chancellor of the University, requested that Locke might now accumulate the M.B. and M.D. degrees. Fearing opposition and rejection, Locke did not submit the request but ensured continuation of his studentship by a royal dispensation.

In 1667 Locke went to London as personal physician to Lord Ashley. This led to his association in clinical work with Thomas Sydenham, and he forsook the laboratory to study disease at the bedside. An early success was his operation on Lord Ashley for a suppurating hydatid cyst of the liver. In 1668 he was elected a Fellow of the Royal Society of London and served on a committee of the Society. In 1670 Lord Ashley nominated Locke for the degree of M.D. Oxon., but Locke asked his patron to withdraw the request on hearing that John Fell, Dean of Christ Church, and the Provost of Eton both opposed the award. When Ashley became Earl of Shaftesbury, Locke was appointed Secretary of Presentations. In 1674 he became M.B. Oxon., a medical graduate at last, but he never proceeded to the M.D. He was appointed to a medical studentship at Christ Church.

In the smoky atmosphere of London, Locke appears to have contracted asthma and chronic bronchitis. After Shaftesbury's fall from power in 1673 he lost his post, and in 1675 he went to France for the sake of his health. He stayed fifteen months at Montpellier studying medicine and science and, afterwards, went to Paris for the same purpose. His medical services were constantly in request by British residents. He revisited Montpellier, then Paris again, and returned to London in 1679. From then until 1682 he was again with Shaftesbury in public affairs and renewed his friendship with Sydenham and other physicians. After Shaftesbury's death he fell under suspicion for his political views and from 1683 until 1689 sought refuge in Holland. Here he wrote his celebrated *Essay*, but also studied Dutch medicine and met scientists and physicians. In 1685, on the order of James II, he was expelled from his studentship.

After the Revolution, he returned to England and accepted the office of Commissioner of Appeals. For his health he spent the winter months with Lady Masham's family at Oates in Essex. In 1696 he was appointed a Commissioner for Trade and Plantations. In 1700 he resigned his appointments, but as late as 1701 he was giving medical advice to some of his poorer neighbours. He died probably from heart failure supervening on bronchitis and emphysema in 1704.

Such in brief outline was the career of this great genius whose medical biography Dr. Dewhurst has so fully and ably put on record.

ARTHUR S. MACNALTY

LAW AND TECHNOLOGISTS

Law and Technologists

By Dr. Roy Douglas. Pp. 158. (London: Gee and Company (Publishers), Ltd., 1964.) 30*s*. net.

LAW and science are rightfully regarded as significant tool subjects for developing the logical mind. It has frequently been argued that a scientific background can be as valuable as a humanistic one for the study of the law. Many scientists and engineers at some stage in their career divert towards the legal aspects of industry and technology. In the world of to-day the applied scientist finds the law increasingly impinging on his activities—employment, contracts, patents, company affairs. A book such as *Law for Technologists* is assuredly, therefore, in principle to be welcomed, though it was written primarily for those studying for the Diploma in Technology and other students who require a measure of legal knowledge as an adjunct to a course which is primarily technological or scientific.

This publication is not submitted as "every technologist his own lawyer", though it provides a brief, lucid insight into the structure and operation of the English legal system and an analysis of certain key topics directly relevant to the application of science or engineering to industry. Anyone so interested reading these chapters will not only be better informed but will also become conscious of the wisdom of the author's injunction "this book may perhaps help people to understand what the law and lawyers are saying, and therefore it may also help them to avoid unnecessary legal trouble—but is most certainly not designed to extricate people from trouble once they have got into it!".

The author has at the outset been faced with the difficult problem of deciding to what extent he is to concern himself with formal aspects, such as the evolution and procedure of the law, in order to help pave the way to an adequate understanding of the substantive portions of his subject. He has attempted to solve this by treating first of all with legal sources and machinery, leaving such matters as proof and international aspects to the last; sandwiched between are chapters on contracts, torts, crimes, master and servant, trade secrets, patents and other monopoly rights and restrictive practices.

It may be commented that the section on private and public companies, which is to be found within the chapter on "Machinery of the Law", would well merit a little expansion into a chapter in its own right, with some reference to the duties of directors; and that perhaps the section on restrictive covenants as regards employees, sound as it is, should fall under the heading "Master and Servant" rather than "Trade Secrets". A list of key reference books on the various legal subjects discussed would be of value.

A word about the selection of cases: this is always a pitfall for the legal writer, but the author has struck a fair balance between ancient historical cases which still to-day often constitute important landmarks in the evolution of the law, and the modern ones which may reflect more directly on present-day industrial conditions. This is particularly noteworthy in the short sections on nuisance and restrictive covenants as between master and servant. It is to be noted that the treatment of the subject of resale price maintenance may shortly be out of date by reason of the new legislation at present before Parliament.

Although limitations of space and the nature of the intended readership have necessitated not only careful selection but also a certain amount of superficial treatment of some subject matter, the style is always readable and intelligible. This book should be of real assistance to those for whom it is primarily intended, even though inevitably they cannot end up with much more than a general appreciation of this complex subject, or rather interrelation of subjects. B. J. A. BARD

A GREAT CIVILIZATION OF ANTIQUITY

Ancient Iraq

By Georges Roux. Pp. 431 + 33 plates + 5 maps. (London: George Allen and Unwin, Ltd., 1964.) 50*s*. net.

THE three great civilizations of early antiquity with the longest past history were those of Iraq, Egypt and China. For Iraq, Dr. Georges Roux has contributed a history from the Palæolithic and Mesolithic periods until about the seventh century A.D., and those who have worked in a part of Mesopotamia will be grateful for his outline history of other parts and periods. The book will also be useful to students who wish to get a general view of their position in any special subject they choose to make their own.

From 1928 until 1934, I was closely associated with the University of Oxford and Field Museum Expedition to Mesopotamia working at Kish (the Harsagkalamma end) under the late Prof. Langdon and the late M. Louis C. Watelin, and was fortunate to be in the field in the year when we at Kish, Sir Leonard Woolley at Ur, and Dr. Jordan at Uruk (the Erech of *Genesis*, now Warka), all reached virgin soil, ourselves after digging through 60 ft. of buried civilizations and passing downward through more than 5,000 years of history. Thus, for the first time, we were able to establish the main succession of events including the position of the three pre-dynastic periods: Al 'Ubaid, with its fine pottery painted with one-colour designs, and copper (including *cire perdue* casting), its affinities in Iran; Uruk, with the origin of writing in pictographic script, its affinities with the north shown by its polished red, polished black and polished grey pottery, and its open-spouted jars; and Jemdet Nasr, with its polychrome red, buff and black pottery, again with affinities with Iran and farther east.

Here, I think, Dr. Roux is rather severe in restricting the Jemdet Nasr period to pottery. I remember well the work of Prof. Langdon in saving at Jemdet Nasr a large number of semi-pictographic unbaked clay tablets and baking and publishing them in the *Oxford Edition of Cuneiform Texts* (7, 1928), each sign with a series of the forms taken by this through all periods to the Assyrian.

More too might have been made of the slow progress in copper and bronze, and the development of iron, both through a long experimental period, and of their diffusion to the rest of the civilized world, and their work on copper and alloy which saved bronze users of other areas from a long experimental chalcolithic period.

In connexion with irrigation, something might be made of the wealth of tablets dealing with water and its use between individuals and between cities. Here perhaps was an early start of the principles of both individual and of international law.

In dealing with chronology, it is somewhat surprising to find no mention of the pioneer work of Langdon and Fotheringham on *The Venus Tablets of Ammizaduga* (found at Kish) with its first establishment of the date of the beginning of the first Babylonian dynasty, later corrected to the next cycle of Venus 275 years later by Sidney Smith and Brigadier-General Sewell in *Alalakh and Chronology*.

Dr. Roux is quite right in his statement that Sumerian and Semite (including Akkadian) are linguistic terms, and not racial, and that there is no racial difference. Both had the Armenoid and Mediterranean mixture, the latter predominating. In my report on the early dynastic skeletal material in *Kish IV*, in agreement with Dr. Dudley Buxton's earlier report in the *Journal of the Royal Anthropological Institute* on a longer series, I mentioned three racial groups, Mediterranean, Eurafrican (a sturdier form of Mediterranean) and Armenoid, and said that throughout Mesopotamian history there was a mixture of the same three races which helped us in excavations to-day.

My few observations are not made in a carping spirit, and I fully appreciate the chapters and sections on law, religion, social and economic life, science, and military and political organization.

To have sorted out the rise and fall of so many cities and dynasties, and to have placed in order so long a period from the Palæolithic to the Parthian, is a considerable achievement, let alone the large amount of varied bibliographical material required to support it, all listed with notes at the end. The book is illustrated, and has four maps of different periods. T. K. PENNIMAN

AGRICULTURAL RESEARCH IN NEW ZEALAND

Thomas Cawthron and the Cawthron Institute

By David Miller. Pp. vi + 248. (Nelson, New Zealand: The Cawthron Institute Trust Board, 1963.) 30*s*. New Zealand currency.

MANY agricultural research institutes were started by benefactions from rich men; the Cawthron Institute at Nelson in the South Island of New Zealand began in this way. The Cawthron family went to New Zealand in 1849 when Thomas was 15; they were poor. Nelson was founded only a few years before the Cawthrons arrived and there were large rewards for hard work and initiative in the rapidly-growing colony. Thomas made a start in business by working as a contractor, first in the Australian gold fields, and afterwards at Nelson. From the late 1850's he had "a thriving business at Port Nelson as a shipping agent, merchant and prudent investor leading to the accumulation of his substantial wealth"—ultimately amounting to £264,000. He had plans to found a Solar Physics Laboratory but died before the arrangements were completed. By his will the bulk of his fortune was left to start "an Industrial and Technical School, Institute and Museum to be called the Cawthron Institute". The Trustees decided that the new Institute should work mainly in agriculture—the main industry of New Zealand—and particularly in fruit growing, which was important around Nelson.

In 1917, just before the Institute was formed, only £10,000 a year was available to Government Departments and the Dominion Museum for scientific research. The Cawthron Institute endowment of £231,000 made much more research possible. Work began in 1920 and for the next forty years was mainly in 'biology' (entomology and plant diseases) and 'agriculture' (soils, plant nutrition and agricultural chemistry). The Institute had many early successes, particularly in the biological control of insect pests, such as woolly aphis, and of weeds, through the introduction of predators. Later, grass grub was controlled by insecticides; this latter work is said to have saved New Zealand farmers £15 million a year. Other pioneer work was in soil surveying, fertilizer use, the control of deficiency diseases in plants and animals, and forestry. By 1959, 760 papers had been published by the staff.

Many agricultural research institutes have expanded greatly in attempts to cover their subjects as more money has become available from Governments. The Cawthron Institute has been an exception; it has started many branches of agricultural research and developed them until they could stand alone. Recent expansions in research in New Zealand have generally involved the formation of new institutes, mostly under the Department of Scientific and Industrial Research. The Institute was reorganized between 1956 and 1959; it still has the autonomy of a privately-endowed institution and works mainly on problems of plant and animal nutrition of the Nelson district.

The first third of the book describes the origins of the Cawthron family and the life of Thomas as colonist, business man, and public benefactor. The next third summarizes the development of the Institute. The remainder of the book lists fully the papers published by Institute staff up to 1959 and gives short biographies of the directors and many senior staff. (David Miller, the author, worked at the Institute for more than 30 years and was director from 1956 until 1959.)

The book is of general interest for its accounts of the career of a distinguished citizen of Nelson (which also produced Lord Rutherford—in fact the Cawthron family arrived there the same year as he was born) and of the development of this part of New Zealand. The excellent history of the first forty years of the Cawthron Institute, and the summaries of investigations that have been done, inevitably make it an essential source-book for all interested in the development and history of agricultural science in the Dominions. There is a good index, and sources of information on the life of Cawthron and the development of Nelson are all listed. G. W. Cooke

FUNGAL AND YEAST CHEMISTRY

The Chemistry and Biochemistry of Fungi and Yeasts

Proceedings of the Symposium on the Chemistry and Biochemistry of Fungi and Yeasts, Dublin, 18–20 July 1963. (International Union of Pure and Applied Chemistry, Royal Irish Academy and Irish National Committee for Chemistry.) Pp. v + 525–705. (London: Butterworth and Co. (Publishers), Ltd., 1963.) 45*s*.

THESE *Proceedings* fall into three unequal parts. Section 1, on "Fungal Metabolites", contains four papers. Under the title "Biosynthesis of Antibiotics", A. J. Birch (United Kingdom) examines the question whether antibiotic production can be manipulated by the chemist to make it more efficient, and whether an individual antibiotic can be endowed with more useful properties by effecting minor alterations in its molecule. Penicillin, tetracyclines, novobiocin, fumagillin and one non-antibiotic substance, gibberellic acid, are used to illustrate how intimate knowledge of details of the metabolic routes involved in antibiotic biosynthesis might be usefully applied for these ends. The remaining papers in Section 1 are excellent examples of the contributions which organic chemists make to biological sciences. D. Dolphin, A. W. Johnson, R. Rodrigo and N. Shaw (United Kingdom) describe, in their paper on "The Vitamin B_{12} Coenzyme", the chemical synthesis from reduced vitamin B_{12} of vitamin B_{12} coenzyme (5′-deoxyadenosylcobalamine) and a range of its alkyl coenzyme analogues. Their properties and reactions seem particularly interesting in relation to possible mechanisms of the biochemical role of vitamin B_{12}. In "Constitution of Rifamycins", V. Prelog (Switzerland) unfolds how the structure of the complex rifamycin molecule has yielded to the formidable weapons of modern organic chemistry. The similar success attending the attack on the sclerotiorin group is described by W. H. Whalley (United Kingdom) in "The Sclerotiorin Group of Fungal Metabolites: Their Structure and Biosynthesis".

Section 2 comprises three papers on "Biochemistry of Fungi": "Fungal Metabolism of Certain Aromatic Compounds Related to Lignin" by M. E. K. Henderson (United Kingdom); "Carbohydrate Metabolism by Fungi" by D. Gottlieb (United States); and "Influence of Peat Substances on the Metabolism of Fungi" by E. Küster (Ireland). The first and final papers of this group contrast sharply with those of Section 1, and show how remote is the stage when the organic chemist will find lignin and peat rewarding subjects for research. Yet lignin, through its role in the maintenance of soil fertility, and peat, because of its economic importance, demand investigation and, as these contributions show, the research prospects in the chemistry and biology of lignin and peat are rich. Dr. Gottlieb presents a general review, surveying the operation in hyphal fungi of the major pathways of carbohydrate metabolism.

Section 3, devoted to "Chemistry and Biochemistry of Yeasts", consists of seven papers. D. J. D. Hockenhull (United Kingdom), in "Changing Approaches to Antibiotic Production", reviews in general terms the historical development of the nutritional and cultural conditions needed for antibiotic production, and develops the thesis that "the concept of antibiotic production as a steady state system based on an understanding of rate processes concerned with the assimilation of simple nutrients is here to stay". The complex subject, "Protein Synthesis in Yeast", is viewed by A. H. Cook (United Kingdom) from four angles: age aspects of yeast cultures, the occurrence and nature of yeast 'peptide-nucleotides', synchronous yeast cultures and enzyme development in yeast. Despite its seemingly academic nature, Dr. Cook aptly indicates possible technical advances resulting from the pursuance of such research as he describes. This point also emerges in the contribution by H. Suomalainen (Finland), "Changes in the Cell Constitution of Baker's Yeast in Changing Growth Conditions", in which are described some changes in the chemical and biochemical make-up of baker's yeast taking place in response to the sequence of environmental changes involved in the stages of its industrial propagation. In "Sulphur Utilization by Yeast", G. A. Maw (Ireland) deals with the distribution of sulphur in *Saccharomyces cerevisiae*, its ability to utilize various sulphur compounds for growth and sulphur transport and uptake in this species. Interest in the glycogen, glucan and mannan of yeast is heightened by recent investigations described by D. H. Northcote (United Kingdom) in "The Structure and Organization of the Polysaccharides of Yeast", in which their chemistry and properties are related to their function and synthesis in the total organization of the cell. G. Ehrensvärd (Sweden), in "Biochemistry of Yeasts—an Analysis of Some Conditions for Growth", reports experiments designed to throw light on the metabolism of acetate and formate during the lag and log phases of growth of the fodder yeast, *Candida utilis*. The final contribution, by S. R. Mardashev (U.S.S.R.), provides "Some Data on the Metabolism of Dicarboxylic Amino Acids and Their Amides in Yeast". In particular, the biosynthesis and breakdown of aspartate, glutamate, β-methylaspartate, asparagine and glutamine by extracts of *Saccharomyces* strains are considered.

This review of its contents indicates that the volume is one for specialists, of whom the yeast specialist is likely to derive the greatest benefit from its perusal. Not only is the largest individual section devoted to yeast (except for Dr. Hockenhull's paper, which is surely more appropriate to Section 1), but also it achieves a better focus than the other sections can hope to achieve, with so few papers in so vast a field, despite the individual excellence of the contributions. The book is well produced and contains few typographical errors, although there are some remarkable Latin plurals on p. 677. C. Rainbow

Progress in Ceramic Science

Vol. 3. Edited by Dr. J. E. Burke. Pp. vii + 262. (London and New York: Pergamon Press, 1963.) 80*s*. net.

THE second volume in this series was reviewed on p. 932 of the March 9, 1963, issue of *Nature*. The present volume contains four essays, the first by Prof. G. W. Brindley (Pennsylvania State University), "Crystallographic Aspects of Some Decomposition and Recrystallization Reactions", in which orientation relationships between parent and product phases are discussed and illustrated, including the aluminium hydrous silicates—a field which Prof. Brindley has made especially his own. The second essay, by F. M. Ernsberger (Pittsburgh Plate Glass Co.), deals with the current status of the Griffith crack theory of glass strength. He surveys techniques (ion-exchange, pulsed-stress, bifluoride etch and sodium-vapour treatment) for the direct detection of Griffith cracks. It is suggested that mechanical-damage cracks form a distinct class of strength-impairing structures, and that the description 'Griffith crack' should be reserved for such defects, distinguishing them from hypothetical intrinsic flaws which are presumably responsible for the failure of glass with damage-free surfaces. There appears to be a good deal of information on this aspect of the problem which so far does not present a coherent picture. A. E. Owen (Westinghouse Research Laboratories) contributes a report on electric conduction and dielectric relaxation in glass, in which, after a brief review of the Zachariasen–Warren work, he outlines the present-day theories of d.c. conductivity and relaxation, directing particular attention to the role of the alkali ion. He feels that, in spite of the present-day work, a quantitative understanding of even the simpler electrical phenomena in glass has still not been achieved. The final essay is by R. L. Coble (Massachusetts Institute of Technology) and J. E. Burke (General Electric Research Laboratory) on sintering. This covers a good deal of fairly well-established work, but is particularly interesting in its comments on the inhibition of discontinuous grain growth and on pore trapping.

The book in some curious way lacks impact, and one must hope that future volumes in this series will be more exciting. However, it is a useful addition to the library and contains extensive bibliographies. N. F. ASTBURY

Encyclopedia of Chemical Technology

By Kirk-Othmer. Executive Editor: Anthony Standen. Vol. 2: Aluminium Compounds to Azo Dyes. Second completely revised edition. Pp. xv + 910. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, Inc., 1963.) 338*s*.

THE publication of the revised second volume of 'Kirk-Othmer' within a year of the publication of the first volume is a notable achievement, and full credit must be given to the editorial board on fulfilling their promise to publish two to three revised volumes per year of this excellent *Encyclopedia of Chemical Technology*.

This volume contains thirty-nine articles ranging from "Aluminium Compounds" to "Azo Dyes", the majority of which appeared in Volumes 1 and 2 of the first edition. Each article, written by a specialist, has been completely revised and extended. For example, "Amines", included in the first edition, has been replaced by three complete articles covering, "Amines aliphatic", "Amines fatty" and "Amines chloroalkyl". New leading articles covering material only briefly mentioned in the first edition include the following subjects. "Antistatic Agents", an article which reviews the theory and use of these agents in fabric and polymer technology. "Aquametry", a review of analytical methods for the determination of water, with special reference to instrumental techniques, such as nuclear magnetic resonance, infra-red and ultra-violet spectroscopy, etc. "Automobile exhaust control", a subject of increasing importance, dealing with the health hazards and methods of control of the exhaust gases from automobile engines.

The preface to the first edition stated that contributions from other countries would be included in an attempt to widen the scope of the *Encyclopedia* beyond the limits of technology in the United States. In this edition attempts to do this have been made by including leading articles written by Swiss, French and Japanese authors. The lists of trade names, although still predominantly of American origin, have all been revised and extended.

It is disappointing that so many of the cross-references that were presented and found so useful in the first edition have been omitted—a loss that will no doubt be overcome when the index volume is published. The omission of the review on "Analytical Chemistry" will, we hope, be replaced by the inclusion, in later volumes, of separate articles on individual analytical procedures. K. FIELD

A Manual of Experiments in Reactor Physics

Edited by Prof. Frank A. Valentine. Pp. xv + 335. (New York: The Macmillan Company; London: Collier-Macmillan Ltd., 1963.) 55*s*.

IT is inevitable that any account of specialized experiments using equipment available in modern laboratories, such as those catering for reactor physics students, must contain a certain amount of detailed description of items of equipment which are special to the country of origin. This means that accounts of experiments and details of how they are to be performed must inevitably lose some of their value in a country other than that which has the equipment readily available.

For non-American users, therefore, this is a fault from which *A Manual of Experiments in Reactor Physics* suffers. However, despite this, it is generally so good an account as largely to make up for this defect. There is an excellent opening chapter on the elementary statistics of experiments, a subject which is so often neglected altogether or dealt with inadequately. This is followed by a short discussion of radioactivity, which includes a description of the method of analysis of decay curves. The standard methods of detection of particles are then described, together with a very short account of some electronic techniques. Also included in this chapter is an account of neutron sources. As a number of the experiments which are described later in the book require a pulsed-neutron source, there is a short discussion of the theory and methods of production of pulsed-neutron sources, and the final chapter in the introductory section (rather less than half the book) deals with radiological considerations relating to safety requirements in a reactor physics laboratory.

The remainder of the book describes actual experiments which fall into three broad categories; those requiring only a steady source of neutrons (ten experiments); those requiring a subscribed assembly and a steady source of neutrons (six experiments); and those requiring a sigma-pile or a subcritical assembly and a pulsed source of neutrons (seven experiments). All are well described according to a standard pattern of introduction, object, theory and method, materials and apparatus, procedure, results and discussion. It should, however, be noted that the theory given generally amounts only to a discussion of the necessary and relevant formulæ required and not to the derivation of them. However, very adequate references are given for the experimenter to be able to read these up for himself.

For those who wish to have ready-made descriptions of many important, yet relatively simple, experiments in reactor physics this is an excellent book, with the proviso that some of the particular pieces of equipment described will not be available outside American laboratories. J. F. HILL

EMERGENCE OF POTATO BLIGHT, 1843–46

By P. M. AUSTIN BOURKE
Irish Meteorological Service, Dublin

NO outbreak of a plant disease, before or since, has received the public attention given to the epidemic of potato blight (*Phytophthora infestans* (Mont.) de Bary) which commenced in Europe in 1845. The detailed consideration of the disease in agricultural journals like the *Gardeners' Chronicle* is not surprising; it is more unexpected to find no fewer than sixty-six entries on the subject in the official Belgian gazette, *le Moniteur Belge*, during the five-month period, August–December 1845, and a number of articles in the French *Journal des Débats*.

The first appearances of blight were mostly recorded in local newspapers, which sometimes were led by political or sectional allegiances to minimize or exaggerate its intensity and extent. In the professional Press, there was quite an amount of sharp jostling as to which group was most competent to deal with the outbreak. The medical men felt that all disease fell within their ambit, so the *Lancet*, in common with the corresponding continental journals, gave considerable space to the epidemic. In Ireland, the *Dublin Medical Press*, feeling the first chill breath of socialized medicine, suspected that Governmental concern about food shortage, famine and fever was merely a stratagem to ease the passage of a "medical charities bill", and for a long time denied the gravity of the situation. The chemists argued that the potato rot was primarily a chemical change and thus came within their field of competence; for this they earned the scorn of the London *Medical Times*, which dismissed them as "the Giessen-bitten boys of the present day", mesmerized by "the tasmalic name of Liebig". Commercial concern, and, in particular, possible repercussions on the grain market, explain the continued interest of journals like the *Mark Lane Express*; but, in fact, every periodical from the *Bankers' Circular* to *Punch* featured blight to such an extent that the American *Monthly Journal of Agriculture* was moved to complain that the British papers of the time spoke of nothing except the potato disease and the railway mania. The botanists and mycologists were quite outnumbered in this rush into print; the plant pathologists had not yet been invented.

The epidemic broke out at an awkward time for the learned societies. Some, like the Société Royale et Centrale d'Agriculture of Paris, were summoned back by ministerial demand from their summer holidays to urgent special sessions; the remainder made up for lost time when they reassembled in the autumn. Many set up special committees to examine and to experiment on the disease, and, in due course, to add to the voluminous and perplexed reports which were emanating from officially inspired commissions in Belgium, Holland, France and Ireland. But it was the pamphleteers who had the real field day. An eruption of brochures broke out all over Western Europe, written by physicians, surgeons, botanists, noblemen, pharmaceutical and other chemists, geologists, excisemen, gardeners and accountants; even a plain housewife added her meed of wisdom. Many of these pamphlets put forward highly eccentric views, but few were without useful factual information.

Although the attack took Europe completely by surprise, blight had already been ravaging the potato crops of North America in the previous two seasons. Stevens[1] has charted the annual progress of the disease, from its beginnings in 1843 in the five States closest to the great ports of the east coast of the United States, to an expanded area in 1845 which closely approximates to the limits within which blight is a serious problem to-day. Fig. 1 is based primarily on Stevens's work, with the addition of a limited amount of extra information on the impact of the disease in Canada. The diagram bears quite a resemblance to charts of the ten-yearly progress of the Japanese beetle from its introduction near Philadelphia in 1916.

From what has been said, it will be clear that there is no lack of material on which to base a similar chart of the geographical progress of potato blight in Europe in 1845; indeed, the major problem is the sheer volume of the relevant data. Eye-witness accounts of the earlier stages in Belgium and neighbouring countries are given by Dumortier[2] and by Martens[3]. Bonjean[4] adds details of the onset of the disease in southern France, Switzerland and north Italy. Münter[5] and others describe its progress in Germany. Decaisne[6] is one of the few to attempt a comprehensive verbal picture of the spread of the disease. In France[7] and in Scotland[8], reports were collected and co-ordinated by a central committee. In Ireland, the constabulary were instructed by an order dated September 16, 1845, to submit periodic confidential reports on the progress of the disease; the original returns from more than 250 police stations are filed in the Public Records Office, Dublin. Data from all these sources and from very many others, including British, Irish, French and Belgian newspapers, are summarized in Fig. 2.

Onset of Potato Blight

The disease was first noticed in the Courtrai area of Belgium towards the end of June 1845. By mid-July it extended all over Flanders, and had appeared in neigh-

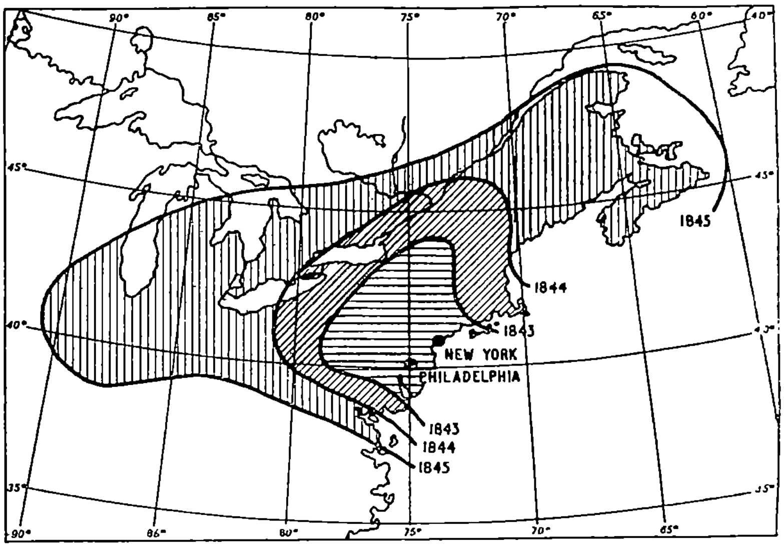

Fig. 1. Approximate extent of potato blight attacks in the United States and Canada during 1843–45 (after Stevens)

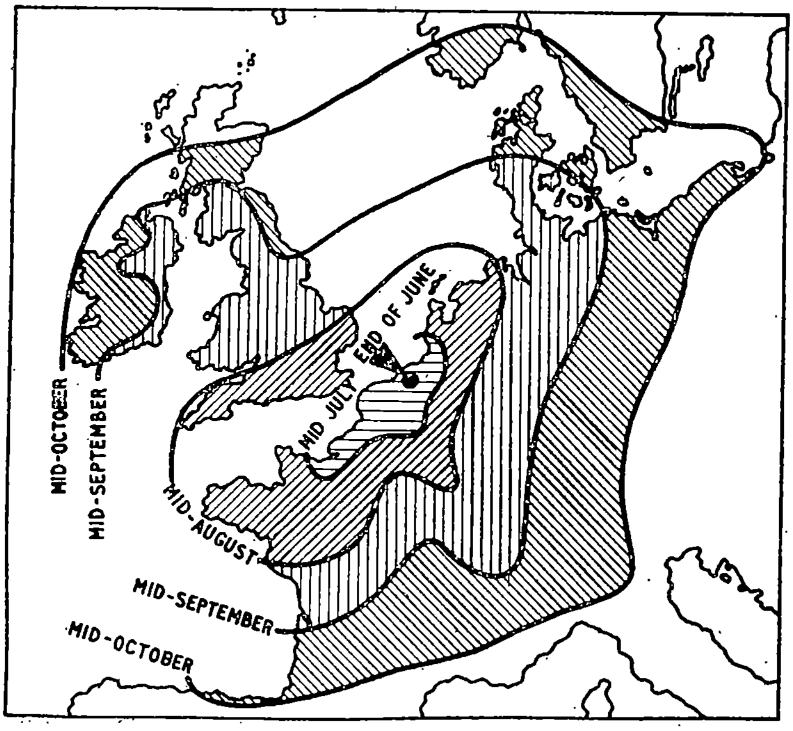

Fig. 2. Approximate dates of first report of potato blight in Europe in 1845

bouring parts of The Netherlands and France. The first newspaper references to the strange and alarming disease occurred in the second half of July. As early as July 31, 1845, *l'Organe des Flandres*, a newspaper published at Gand, printed an article by the Abbé Édouard van den Hecke, in which he suggested that the disease was due to a fungus which he described briefly, with particular reference to the remarkable mechanism by which it launched its spores. A previous suggestion as to the fungal nature of potato blight had been made in the United States by Mr. J. E. Teschemacher of Boston, but had caused no reaction there. Van den Hecke's independent conclusion proved to be the first innocent shot in what soon developed into a violent controversy between those who considered the fungus to be the unique cause and those who dismissed it as a consequence of the disease. There were authentic grounds at the time for scientific doubt, but the issue was embittered by personal jealousy, international rivalry and even religious conviction. The standard bearer of the fungal theory was Prof. Charles Morren of Liège, who launched, in the Brussels newspaper *l'Indépendence belge* of August 20, 1845, a vigorous manifesto which was reproduced all over Europe and in the United States. He was supported by Rev. M. J. Berkeley in England and, more cautiously, by A. Payen in France; but the opponents of the theory were far more numerous and influential, and carried the waverers with them. The fungal theory quickly fell into disfavour with all except the faithful few, and did not emerge from the shadows until de Bary's time, some fifteen years later.

Spread of the Disease

To return to Fig. 2, the extension of the disease from Belgium to Luxembourg seems at first to have been blocked by the Ardennes; it did not appear there until it had flanked the mountains from north and south. At a later stage, the entry of the disease into Switzerland appears similarly to have been made, virtually simultaneously in September, along the valleys of the Rhône and the Rhine.

The disease was found in the Paris area about mid-August. On August 20, M. Élisée Lefebvre showed examples of blighted potato foliage and tubers to a session of the Société Royale et Centrale d'Agriculture. In Paris also, Dr. C. Montagne hastened to comply with the botanical canons by describing the fungus in proper detail to a meeting of the Société Philomathique on August 30, and thus gained priority over a number of Belgian writers—van den Hecke, Anne Marie Libert, René van Oye and Morren—who had already given less formal accounts of the fungus in popular newspapers.

By mid-August the disease had also extended to the lower Rhineland, to north-west France, to the Channel Islands and to southern England. In England, the alarm was first sounded by Dr. Bell Salter of the Isle of Wight in a letter which appeared in the *Gardeners' Chronicle* of August 16; the following week's issue confirmed the presence of the disease over much of southern England. It had not yet appeared in the Midlands, for when Rev. M. J. Berkeley of King's Cliffe, Northamptonshire, received on August 26 some infected foliage from his friend Dr. Montagne in Paris, he had not succeeded, despite careful search, in finding any traces of the disease in his area. A few days later it made its appearance, and he followed its progress in the field and checked its characteristics against Dr. Montagne's specimen and description.

The advent of potato blight in Ireland was announced simultaneously, on September 6, in brief paragraphs in the *Waterford Freeman* and the *Dublin Evening Post*. On September 13, Dr. John Lindley, impressed by the advanced stage of destruction of the potato crops in the London area, stopped the press to announce the grim news from Ireland in the *Gardeners' Chronicle*. In Ireland itself, however, the newspapers and journals, irrespective of their political allegiances, tended in the earlier weeks to play down the disease, and it was not until considerable tuber rot was noted at harvest time in October that the popular panic spread to the Irish newspapers.

In the later stages of a potato-growing season, it is difficult to distinguish the effects of blight on haulm which is ripening to decay. The outer boundary line in Fig. 2 thus encloses, in large part, areas in which tuber blight was discovered at or soon after harvesting. It is difficult to place with absolute certainty in Scandinavia and central Europe. There is little doubt that the disease in Scotland was virtually limited to the area south of the Grampians and, in particular, did not extend to the Highlands in 1845. Neither did it appear in the Shetland, Orkney or Scilly Islands, and it made little or no impact in Achill Island on the Irish west coast. The southern limit of the disease did not quite reach the Mediterranean, with the possible exception of the Genoa area about which there were conflicting reports.

Extent of Crop Losses in 1845

Losses in the potato crop in 1845 were most severe in the area of earliest attack. In Belgium, Holland and north-east France, the foliage of the main crop was destroyed in most cases while the tubers were no bigger than marbles. In the regions of late-season attack where the potatoes were almost fully developed, the extent of loss by tuber rot depended on the wetness or otherwise of the season before and at harvest time. In rainy areas, losses were quite serious, particularly where panic digging took place while the fungus was active. Appreciable damage was suffered in parts of Switzerland, and the ffect on the lives of the poor is vividly described in the well-known novel, *Käthi, die Grossmutter*, by Jeremias Gotthelf (Albert Bitzius), published in 1847. In Ireland, he effects of the disease were very variable; but the mean loss by tuber rot was about 40 per cent in a crop which had yielded remarkably well, so that the production of sound potatoes was about a quarter or a third below normal. In Bavaria and Prussia, where the autumn was dry, crop losses were slight. A contrary mpression was created abroad by the decision of the Prussian Government, by a decree dated September 18, 1845, to prohibit the export of potatoes, but this was merely a temporary safeguard directed against heavy buying by Belgian and Dutch importers.

Pattern of Blight Progress in 1845 and 1846

Outside Belgium, the pattern of disease progress in 1845 (Fig. 2) passed virtually unnoticed, and in each area which was attacked later in the season there was a tendency to interpret the data as showing a linear progression. Thus, in Britain, the apparent path from Belgium through England to Ireland was extrapolated backwards to include Germany and even Poland; the outbreak of blight was thus seen as "coming from the east", and, with the path of the cholera pandemic of 1826–37 still fresh in the public mind, the disease was often described as the "potato cholera". In the south of France, potato blight appeared to travel from north to south, and its late season appearance was interpreted as support for the theory that the potato was suffering from a kind of cool weather degeneration. Writing about forty years later, Jensen of Copenhagen[9] recalled the sequence of successive blight appearances in 1845 from the Isle of Wight through England to Scotland, and from The Netherlands through Holstein to Denmark, and claimed that it was identical with the apparent progress of the disease in normal later years, as controlled by climatic factors.

In fact, however, the cycle of events as shown in Fig. 2 is completely untypical of the annual course of potato blight in Europe, nor is it explicable in terms of abnormal weather conditions. The summer of 1845 in north-west Europe was everywhere cold, sunless and wetter than normal, but, while it was a depressing season, it was by no means an unusual one. Growing seasons more favourable to blight development had occurred in every part of the region within the past 3–6 years. The only adequate explanation of the pattern of development of blight in 1845 is that the fungus had recently been introduced into Europe, and that the main concentration of inoculum in that year lay within the region in which the disease was obvious by mid-August.

This interpretation is reinforced by the sequence of events in 1846 when the apparent geographical march of the disease followed what was afterwards to be recognized as its characteristic climatic pattern[7,10]. It first appeared in the west, striking Ireland fully two months before it was noted in the previous year, and its apparent progress was eastwards or north-eastwards "at about 50 miles per week". In Ireland the crop was destroyed in most cases in early August at a time when tuber formation in the main crop, then sown later than nowadays, had barely begun. The sole food of a great part of the population was thus wiped out, and the year which followed marked the most intense stage of the great hunger so eloquently described in Mrs. Woodham-Smith's book[11]. The Scottish Highlands, which had emerged unscathed in 1845, suffered an early and severe attack of blight in 1846, and distress in this area was second only to that in Ireland[12]. In south-east England and on the neighbouring European mainland the disease not only appeared later, but also, since the summer there was dry and warm, such damage as the potato crop suffered was due more to drought than to blight.

In 1846, the disease made an appearance in new areas on the European mainland, in the Orkney and Shetland Islands, and even in Algeria.

A Political Consequence

The different courses of the disease in 1845 and 1846 had political repercussions which are of some historical interest. In 1845, the London area was attacked sooner and more spectacularly than was Ireland. We have seen that Dr. Lindley, in his *Gardeners' Chronicle*, was already sounding the alarm for Ireland a month before the Irish journals commenced to treat the matter seriously. As a result, Peel's Government in London took prompt action, required the constabulary to survey the Irish crops, and set up a scientific commission of three, including Lindley, to go to Ireland and report on the situation. Impressed by Lindley's estimate that five-sixths of the Irish potato crop would be lost, Peel placed an early order for maize in North America. The provision made was parsimonious by modern relief standards; but, since the actual loss was only about half the original estimate, the emergency measures blunted the sharper edge of starvation in the spring and early summer of 1846.

By the time the disease reappeared in Ireland in 1846, the parliamentary opposition which had berated Peel for exaggeration and unjustified panic was itself in power. Further, the disease was rampant in Ireland at a time when south-east England was virtually free. Russell's Government, treating the earlier appeals from Ireland as cries of 'Wolf!', moved with tragic slowness and inadequacy. Meanwhile, in Ireland, Lindley's forecast was being more than justified, with a time-lag of a year. The result is a matter of history.

A New Disease?

Although most observers in 1845, and particularly practical farmers, insisted that blight was a disease new to Europe, there was by no means complete agreement on the point. A new appearance was difficult to explain, irrespective of the theory advanced, and there was a rich source of error in the confusion of blight with earlier potato diseases, which was mined with particular industry by the academic commentators who lacked direct experience of the disease in the field. There were also those who felt that the first need was to dispel public panic and that this consideration justified the mild deception of identifying the disease with earlier outbreaks which had died down after a short period.

In the past, the potato had suffered from drought in dry seasons, from water-logging and consequent rot in wet years, and from frost damage in growth and storage when the weather was unusually cold. It was also subject to a number of minor ailments, like scab, which were more a nuisance than a matter of concern. Two diseases only had claimed major attention. The first was the 'curl', which we can now recognize as a virus attack. This was prominent from the last quarter of the eighteenth century and gave rise to a voluminous literature which has been fairly exhaustively reviewed by Atanasoff[13]. The development of new varieties and the regular replacement of seed potatoes from areas free of the complaint proved to be effective devices for the restraint of 'curl'. It led, however, to a continuous and uncontrolled exchange of potatoes which guaranteed the rapid extension and development of any new plant diseases.

The 'curl' differed so radically from blight that it is difficult to credit that anyone could confuse them; yet there was a small group who wielded Occam's razor with fanatical zeal and argued that 'curl', blight and other maladies of the potato were merely different aspects of a single disease.

The 'taint' or 'dry rot', now recognizable as a fungal infection caused by ***Fusarium*** spp., appeared to a troublesome degree about 1830 and caused serious concern in Germany towards the end of the same decade. Again there was a voluminous output of articles, prize essays and pamphlets, culminating in the famous study by von Martius in 1842 (ref. 14).

Again, the course of the disease was quite distinctive, and only a small group of contemporary observers took the line that dry rot and blight were two aspects of a single malady, the respective characteristics developing according as the season was dry or wet. They were sufficiently vocal, however, to create a confusion regarding the time when blight first appeared in Germany and elsewhere in Europe. This confusion has persisted to the present day and has led to the supposition, which is in reality an extension of the cholera fallacy, that the disease might have travelled from Europe to North America.

The fact is that if blight existed in Europe prior to the 1840's, it passed completely unnoticed either by von Martius, who carefully recorded even the minor ailments of the potato, or by the hundreds of other commentators who wrote on the potato. All the evidence points to the conclusion that blight had arrived in Europe only shortly before the epidemic of 1845.

Date of Introduction of Potato Blight into Europe

Accepting that the fungus had been recently introduced, the question arises as to whether the spread of blight in 1845 to a large part of Europe could have occurred in the course of a single season. The possibility cannot be entirely ruled out. It was a summer in which shallow thundery depressions penetrated into the continent and gave rise to a recurrent wind pattern which favoured the transport of spores eastwards as well as westwards in moist sunless weather.

A further favourable factor was the extreme susceptibility to blight of most of the potato crop of the time. No variety proved immune, but a few showed a fair resistance to the disease; it was from a build-up of these partially resistant potatoes that the crop continued to be grown successfully up to the time, towards the end of the century, when treatment with fungicides came into use. But the varieties then most widely grown, such as the 'Lumper' in Ireland, proved highly susceptible and went out of general use after 1846. No doubt there was much exaggeration in the frequent reports of fields which were blackened overnight or even in a matter of hours. But there is solid evidence that the disease worked its destruction with terrifying rapidity. This has recently been confirmed in a remarkable way by Prof. van der Plank[15]. Using potatoes from a stock introduced by missionaries into Basutoland in 1833, which have since then survived in an ambient unfavourable to blight, he has tested the old varieties and found them to be intensely susceptible to the disease.

There is, however, some evidence that blight was already present in parts of Europe in 1844, when the summer was mainly dry. The areas for which a prior appearance are claimed with some plausibility are Belgium, the Lille district in France, the south-east corner of England (Kent and Sussex) and Dumfriesshire in Scotland. There are some reports in 1845 of appearances of the disease in Cheshire and in Dumfriesshire some weeks earlier than the orderly advance depicted in Fig. 2 would suggest. Claims from South Africa, Poland and Portugal that the only crops in which blight appeared were grown from British seed potatoes of the 1844 crop would be decisive, if one could be sure that the disease in question was, in fact, blight. However, the accumulation of evidence does suggest strongly that the disease had already gained a foothold in 1844. There are isolated grains of evidence that the disease may have dated back locally to 1843 or even 1842, but they are far from conclusive. For 1841 and earlier, there is little risk in a dogmatic claim that potato blight did not then exist in Europe.

Source of Blight

It may be deduced with some confidence that blight was not introduced from Europe into the United States; it may have come from the latter, where it was already widespread in 1843, to Europe or it may have arrived independently in the two areas from a common third source. Where this source was located remains a debatable point, on which further detective work is required. Modern commentators have suggested Mexico[16]. Recent work by Dr. Niederhauser *et al.*[17] has shown that the blight fungus there comprises a highly specialized population of races and that it retains the power to mate and form oöspores freely. These characteristics give strong support to the claims of Mexico as the primary site of origin of potato blight; they are less convincing as evidence that Mexico was the immediate source of the less versatile fungus which invaded the United States and Europe.

The nineteenth-century theory was that blight came from the northern Andes region in South America. The direct evidence that the disease existed there prior to 1845 is not very satisfactory; but the region has recently proved to be one in which genes of hypersensitivity to blight occur in wild potatoes[18]. Certainly, the timing and method of disease entry are easier to demonstrate for the Andes area. The newly independent South American States opened up trade with Europe and North America, and this was greatly expanded with the guano boom which commenced in 1840. The problem of the dry rot may have induced the European growers to experiment with fresh stocks from South America, "the home of the potato". Certainly the guano ships brought South American potatoes to Europe, and among the newly introduced varieties which went down in the first attack in Belgium in 1845 were three which bore the significant names, 'Lima', 'Péruviennes' and 'Cordillières'[6]. The available evidence suggests that the disease may well have come from the Andes area; but there are several outstanding problems to be solved before a dogmatic answer can be given.

Acknowledgments

The investigation of potato blight and weather in the 1840's, on which this article is based, was partially supported, in the earlier stages, by a grant from the Scientific Activities Fund of the Royal Meteorological Society and, more recently, by a travel grant, *GA AGR* 6407, from the Rockefeller Foundation.

Pergamon Press Publications

Oxygen in the Animal Organism

Edited by **F.Dickens** and **E.Neil**, Middlesex Hospital Medical School, London

Proceedings of a symposium held at Bedford College, University of London

Partial Contents:

Some studies on the reactions of oxygen and carbon dioxide in haemoglobin solutions in blood – F.J.W.Roughton; Chemistry, genetics, and function of invertebrate respiratory pigments – configurational changes and allosteric effects – C.Manwell; The regulation of carbohydrate utilization – J.M.Lowenstein; The oxygen electrode – I.S.Longmuir; Reflex circulatory and respiratory responses to hypoxia – M.de Burgh Daly; Aerobic work capacity – Per-Olof Astrand and E.H.Christensen; Oxygen consumption and sodium reabsorption in the mammalian kidney – K.Kramer and P.Deetjen; Problems of oxygen supply during exposure to high g – A.G.H. Bjurstedt; Oxygen and the evolution of biochemical pathways – J.Lascelles.

International Union of Biochemistry Symposium Series: Volume 31

712 pages. £10 (approx. $30.00)

AGARDograph 57
Solid Circuits and Microminiaturization

Edited by **G.W.A.Dummer**, Royal Radar Establishment, Great Malvern, Worcestershire

Contains the papers presented at a conference held at the West Ham College of Technology

Partial Contents:

Status and trends in microminiaturization – J.S.Walder; The design and manufacture of solid circuits – J.T.Kendall; Characteristics and application of micrologic elements – P.H.Beneteau and S.Iannazzo; A tunable solid-circuit filter for use in an I.F. amplifier – T.E.Price; An equipment maker's views on some microminiature systems – A.T.Lawton; The applications of solid state circuits to computer design – M.Gribble; Integrated tunnel diode circuits – C.P.Sandbank.

360 pages. 60s ($8.50)

Radiative Heat Exchange in the Atmosphere

K.Ya.Kondrat'yev, Leningrad University, U.S.S.R.

Contents:

Thermal radiation. Basic definitions and concepts; Fundamentals of the theory of actinometric measurements of thermal radiation fluxes; Absorption of long-wave radiation in the atmosphere; Calculation of the transfer of thermal radiation – general solution: Methods of approximate calculation of radiative heat transfer in the atmosphere; Atmospheric emission and the net radiation at the ground; Radiation balance; Temperature changes in the atmosphere caused by radiative heat exchange.

Approx. 424 pages. 100s ($15.00)

Progress in Oceanography
in 3 volumes

General Editor: **Mary Sears**, Woods Hole Oceanographic Institution, Massachusetts

Volume 1

Contents:

Geological investigation of near-shore sand-transport – E.Seibold; Electrification of the atmosphere – D.C.Blanchard; Suspended organic matter in sea-water – T.R.Parsons; The salinity problem – R.A.Cox; Gulf Stream '60 – F.C.Fuglister; Indexes.

396 pages. 100s ($15.00)

Volume 2

Contents:

A survey of marine bottom samplers – T.L.Hopkins; The major deep-sea expeditions and research vessels 1873–1960 – a contribution to the history of oceanography – G.Wuest; On the vertical distribution of zooplankton in the sea – K.Banse; The distribution of phosphorus and oxygen in the Atlantic Ocean as observed during the I.G.Y. 1957-58 – D.A.McGill.

276 pages. 80s ($12.00)

Volume 3 to be published in 1965

Investigations into Electrical Discharges in Gases

Edited by **B.N.Klyarfel'd**, All-Union Electrotechnical Institute, Moscow

Partial Contents:

On discharge striking in polyatomic gases at $pd<(pd)_{\min}$ – L.G.Guseva; The spread of plasma from discharge – I.V.Krapivina; Recovery of breakdown strength after a spark discharge – A.V.Rubchinskii; Extinction of an auxiliary arc at high rates of decrease of the discharge current through a mercury-arc rectifier – V.M.Mantrov; On the spraying of droplets by the cathode spot in a mercury arc discharge – Ya.Ya.Udris; Dynamic changes of vapour density in a high-voltage mercury-arc rectifier – A.A.Timofeev; Distribution of current density on the surface of anodes in mercury-arc rectifiers – N.A.Neretina.

269 pages. 84s (approx. $12.00)

Cerebral Infarction

A.Barham Carter, Ashford Hospital, Middlesex

Contents:

Anatomy and physiology; Pathogenesis – arterial factors; Pathogenesis – circulatory factors; Cerebral embolism; Cerebral thrombosis – atheromatous cerebral infarction; Differential diagnosis – clinical aspects and special investigations; Natural history and prognosis; Treatment – general management and specific medical and surgical therapy; Treatment – anticoagulant therapy; Results of treatment – personal series; Treatment – physiotherapy; Rehabilitation.

224 pages. 63s ($9.50)

South Wales in the Sixties
Studies in Industrial Geography

Edited by **G.Manners**, University College of Swansea

Contents:

The evolution of the regional economy – W.E.Minchinton; A profile of the new South Wales – G.Manners; The coal industry – G.Humphrys; The steel industry – K.Warren; Aspects of the geography of employment – H.W.E. Davies and F.F.Hagger; The measurement of diversification – E.C.Conkling; Toward a new regional economic policy for South-West Wales – Susanne H. Spence; Transport geography – G.Manners; Appendices; Index.

276 pages. 50s (approx. $6.50)

B.D.H. ENZYME ASSAY SETS

for SGO-T
SGP-T
LDH

The B.D.H. Enzyme Assay Sets contain stable solid substrates and ancillary reagents in pre-weighed quantities, from which substrate and other solutions for enzyme assays can conveniently be prepared in amounts sufficient for a specified number of tests as required.
Each set provides for the calibration of the substrate against the user's spectrophotometer or calorimeter, and includes a pamphlet fully describing the method of assay, though the sets are suitable for most published methods and modifications, including automatic methods.

Assay Sets for SGO-T
(Serum L-aspartate: 2-oxoglutarate aminotransferase)
For 100 tests; reagents may be
prepared for 25 tests at a time Each **55s. 0d.**

Assay Sets for SGP-T
(Serum L-alanine: 2-oxoglutarate aminotransferase)
For 100 tests; reagents may be
prepared for 25 tests at a time Each **55s. 0d.**

Assay Sets for LDH
(L-Lactate: NAD oxidoreductase)
For 50 tests; reagents may be
prepared for 10 tests at a time Each **72s. 6d.**

B.D.H. Enzyme Assay Sets may be stored under normal laboratory conditions in temperate climates. Pamphlets on the method of assay and the preparation of the calibration curve are enclosed in each, and information copies will gladly be sent on request.

SPACE AND TIME IN CHEMISTRY*

By Prof. ALLEN MACCOLL
Department of Chemistry, University College, London

THERE seems good reason for a practising scientist occasionally to spend a little time in reviewing the wider area of science into which his interests fit and in assessing their relationship to the subject as a whole. I therefore propose to examine the structure of chemistry and the way in which my own research interests fit into the general pattern. Traditionally, chemistry is divided into three main areas, inorganic, organic and physical. As chemistry occupies a place between physics on one side and biology on the other, further subdivisions have occurred, leading, for example, to chemical physics and biochemistry. This immediately poses the question, from the point of view of a physical chemist, as to whether the traditional subdivision is necessarily the most natural or convenient one. Especially from the point of view of a physical chemist, since his subject has to do more with methods of investigation and with theories, than with synthesis and analysis, which are the stuff of organic and inorganic chemistry. The physical chemist must provide the basic ideas that underpin progress in the other two main areas of chemistry. In the analysis of chemistry which I am going to develop I claim no originality. What I am in fact doing is borrowing as my theme part of the title of Ingold's book, *Structure and Mechanism*. Since I am going to use these terms quite extensively let me first explain what I mean by them.

The term 'structure' is used at three different levels in chemistry. In the first place the organic and inorganic chemists use the term in an almost topological sense in saying that the structure of a molecule is known when the spatial arrangement of the atoms forming it is known, but not necessarily the distances between them. Thus at this level (Fig. 1) the cobaltinitrite anion is described as six nitro groups surrounding a central cobalt ion octahedrally, and the ketene molecule as one carbon atom to which two hydrogen atoms are attached, joined to a second carbon atom, which in turn is attached to an oxygen atom. The second sense in which the term 'structure' is used is essentially a geometrical one; the distances between the atoms in a molecule are specified as are the angles that a pair of atoms subtend at a given atom. By various physical techniques the structures in this sense of the two compounds mentioned earlier have been determined leading to the distances and angles shown in Fig. 1. The third sense in which the term 'structure' is used relates to the way in which the electrons which bind together the nuclei of molecules are organized. This description is essentially a mathematical one.

The three levels discussed here may be differentiated by the terms 'chemical', 'physical' and 'mathematical'. In the chemical method of approach to questions of structure, the behaviour of a substance in a series of chemical reactions is observed and deductions made as to the structure of its molecules. Thus the tetrahedral structure of methane, the planar structure of benzene and the octahedral structure of the cobaltamines were all inferred by this method and represent some of the highlights of deductive reasoning in chemistry. This approach was equally successful in the investigation of the structure of complex, naturally occurring, organic molecules. In the physical method of approach, not only the topology but also the metrical properties of molecules are established. The most powerful technique is that of X-ray diffraction, in that it can fix to a very high degree of precision the positions of all the atoms in a molecule. Spectroscopy, for small and intermediate-sized molecules, can also yield precise values of the structural parameters of molecules. Again there is a recently developed technique which is closely related to the chemical technique discussed here, namely, mass spectrometry. In this a beam of electrons is used to fragment a molecule and structural deductions can be drawn from the nature of the fragments. I shall have more to say about this method later. Finally, there is the third, or mathematical, approach which, by using the techniques of quantum mechanics calculates the energy of the molecule in terms of structural parameters, and thus is able to predict the stable structure. Since problems of structure are of importance for the excited states of molecules as well as for the ground-states, problems of the energy-levels of atoms and molecules can rightly be included within the general term structure as developed here; and so can energy relationships between atoms and molecules.

Mechanism is concerned with the intimate details of the way in which molecules interact to give new molecules. It too can be subdivided in the same way as structure. Thus there are again three levels at which mechanism can be investigated, namely, the chemical, the physical and the mathematical. In the first the method is to take a parent molecule and to substitute various groups at different positions in order to find the effect on the rate of reaction. In the physical method, since it is known that two molecules can only react when they possess excess energy, the question arises as to how they gain or lose this energy. In the mathematical approach an attempt is made first to calculate how the energy of a molecular system varies with various displacements of the constituent atoms and, secondly, to calculate the rate at which the displacement leading to reaction will occur. The chemical method has been widely used in investigations both of reactions in solution and of reactions in the gas-phase. The physical method, based as it is on examinations of intra- and inter-molecular energy transfer, is developing very rapidly at present. The mathematical method, because of the inherent difficulty of the problem, has not as yet been widely applied, although the general principles underlying such a treatment are becoming clearer.

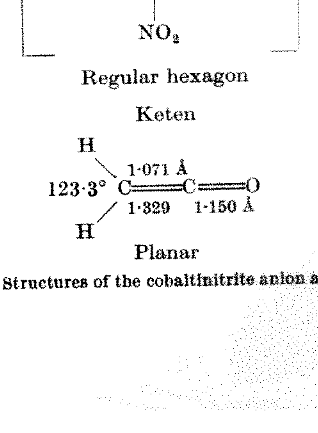

Fig. 1. Structures of the cobaltinitrite anion and of keten

---

* Substance of the Inaugural Lecture delivered on April 28.

Chemistry is essentially the study of interactions, for it is only by allowing the substance that we wish to investigate to interact with something else that we can learn anything about it. Thus we can examine the relation between the pressure and volume of a gas by investigating its interaction with the walls of the containing vessel. By a refinement, the interactions between the molecules themselves can also be investigated by the same technique. So it should not seem surprising if the term interaction looms large in a classification of chemistry. One possible classification is shown in Table 1. This is based on the three methods, namely, mathematical, physical and chemical, by which chemical phenomena can be investigated. No mention is made of the classical subdivisions, namely, inorganic, organic and physical. This is the logical outcome of the physical–chemical approach.

Table 1. A Subdivision of Chemistry

STRUCTURE	MECHANISM
Mathematical Quantum mechanics	
Interaction of electrons and nuclei in atoms and molecules. Bonds and intermolecular forces.	Interactions of atoms and molecules with fields (for example, radiation), with particles (for example, electrons) and with each other (chemical reactions).
Statistical mechanics	
Systems in equilibrium	Systems not in equilibrium
Physical	
The interaction of atoms and molecules with fields and particles. Non-reacting interactions of atoms and molecules with each other. Reacting interactions of atoms and molecules with each other.	Rates of intra- and inter-molecular energy transfer. Rates of reaction from the properties of atoms and molecules.
Chemical	
The stoichiometry of chemical reactions. Structure by the study of the interactions of chemical substances. Substituent effects on equilibria.	The effect of substituents on the kinetics of reacting systems.

Such a scheme is based on a vertical division according to whether or not time is one of the variables investigated, and a horizontal division according to the method of investigation used.

This subdivision allows us to see that what is normally called 'physical chemistry' provides the scaffolding inside which chemistry can be built. The correctness of this view was by no means so apparent a few decades ago when inorganic and organic chemists used the simplest of physical techniques in their problems. This raises one of the most important pedagogical difficulties for the teachers of physical chemistry. Some of the more complex concepts and methods of physical chemistry are required in the early stages in the teaching of inorganic and organic chemistry; long before they can be rigorously presented. Two examples come to mind—the use of equilibrium theory in a discussion of the properties of inorganic systems and the use of spectroscopic data in the determination of organic structures. In both cases, the best solution seems to be to give a short phenomenological discussion of the topic, in order to enable the method to be applied, and postpone the more rigorous discussion until later in the physical chemistry course.

Physical chemistry has two major contributions to make in the development of a chemist. The first of these is the imparting of a sense of rigour, so well exemplified in the study of thermodynamics. This subject plays much the same part in the development of the young chemical mind as does geometry in the development of the young mathematical mind. It is a discipline in the real sense of the term; if one proceeds logically within its framework, one cannot be led to the wrong conclusion. The second contribution lies in the area of numerical analysis. An ability on the part of a student to produce formulæ relating chemically significant quantities counts for little if he or she is unable to apply these formulæ to specific examples and to get chemically sensible answers. By a judicious selection of numerical problems the development of a feeling for the quantitative aspects of chemical phenomena can be developed in the student, a feeling that will be of the utmost importance in his future scientific life, whether in pure or applied research. Much more serious than the lack of ability of a student to get the correct answer to a problem is his lack of realization that the answer he has produced may make chemical nonsense. This feeling for the quantitative aspects of chemistry will also facilitate the making of rapid order-of-magnitude calculations, which are an important guide in accepting or rejecting a possible interpretation of experimental results.

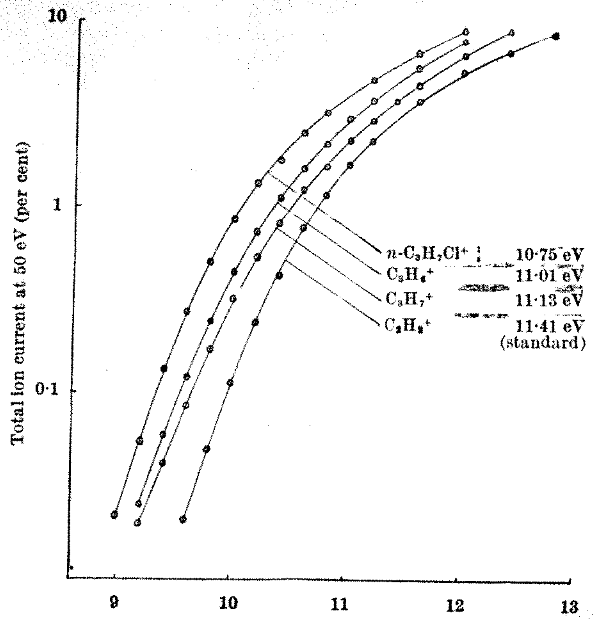

Fig. 2. Ionization efficiency curves for species derived from *n*-propyl chloride

I would like now to turn to the areas of chemistry in which my collaborators and I are most actively working. We are interested both in structure and mechanism. It is only very recently, thanks to the Department of Scientific and Industrial Research, that we have been able to enter the field of structure by the acquisition of a high-resolution mass spectrometer. Work in mechanism through the kinetics of gas-phase reactions has been proceeding for more years than I care to remember.

A mass spectrometer is an instrument which takes a beam of atoms or molecules and sorts them according to their mass, just as an optical spectrometer takes a beam of light and resolves it into its component wavelengths. In its simplest form (Fig. 2) the mass spectrometer uses a beam of electrons to knock off an electron from a molecule, forming a beam of charged species or ions:

$$M + e \rightarrow M^+ + 2e$$

for example:

$$C_3H_7Cl + e \rightarrow \{C_3H_7Cl\}^+ + 2e$$

The ions are then accelerated by an electric field along the line of motion, and mass analysis is effected by a transverse magnetic field, the ions of a given mass being brought to a focus and finally collected. For a given velocity of the ions, and a given magnetic field, the heavier ions are deviated from a straight-line course less than the lighter ones. This property provides a means of weighing atoms and molecules. Such an instrument is known as a single-focusing mass spectrometer. In addition to the magnetic analyser there is included an electrostatic analyser, and the geometry is such that the ion beams may be brought to a very sharp focus. This is known as a double-focusing mass spectrometer, and it can be used for very accurate mass measurements, as we shall see later.

Besides being used for determining the masses of charged particles, the mass spectrometer may also be used for an investigation of the energetics of ionization. For if we vary the energy of the ionizing electron beam we can determine the minimum energy required to ionize a given molecule, namely, the ionization potential. Fig. 2, which gives a plot of the logarithm of the ion current against the energy of the electron beam, shows the way in which the former increases as the latter decreases. In an actual determination of an ionization potential, a standard substance (acetylene in this case) is added along with the unknown (n-propyl chloride) and the efficiency curves for these two species are the inner and outer ones. The horizontal distance between the curves then gives the difference in ionization potential between the unknown and the known species. In this way, the ionization potential of n-propyl chloride has been determined as 10·75 eV.

Besides merely ionizing a molecule, the electron beam may fragment it:

$$M + e \rightarrow P^+ + Q + 2e$$

for example:

$$C_3H_7Cl + e \rightarrow \{C_3H_7\}^+ + Cl + 2e$$

and the minimum energy required to produce a fragment P^+ is known as the appearance potential of P^+ or $A(P^+)$. This quantity is of importance, since it leads to chemically important information regarding the chemical bond. For consider the fate of a species RX. This can fragment in three different ways to give $R + X$, $R^+ + X^-$ or $R^+ + X$. The energy required to bring about the first process is known as the homolytic bond dissociation energy $D(R—X)$, that for the second is the heterolytic bond dissociation energy $D(R^+X^-)$, while that for the third, as we have already seen, is the appearance potential of R^+ from RX. There is one further quantity required, namely, the ionization potential of the radical R, namely $I(R^+)$. The relationship between these quantities is shown in Fig. 3, $I(X^-)$ being the electron affinity of X. It is immediately apparent that:

$$D(R—X) = A(R^+) - I(R^+)$$
$$D(R^+X^-) = A(R^+) - I(X^-)$$

and that these two quantities may be obtained if one can determine $A(R^+)$, $I(R^+)$ and $I(X^-)$. Returning to Fig. 2, it is seen that the appearance potential of the n-propyl ion $(C_3H_7^+)$ is 11·13 eV. This gives for the heterolytic bond dissociation energy of n-propyl chloride the value of:

$$11{\cdot}13 - 3{\cdot}80 = 7{\cdot}33 \text{ eV} = 169 \text{ kcal mole}^{-1}$$

3·80 eV being the electron affinity of chlorine. The relevance of such an investigation of energetics will be seen when we come to discuss our interests in mechanism.

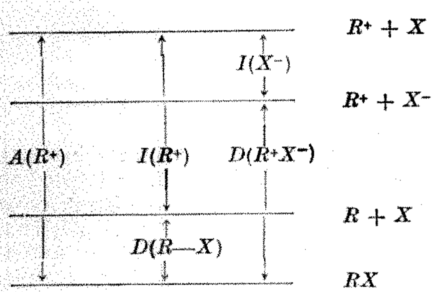

Fig. 3. Energetics of ionization and dissociation

Leaving now for a while the energetics of ionization, let us examine some other implications of fragmentation. The first arises from the fact that the mass spectrum of a molecule is normally uniquely characteristic of that molecule; it can be regarded as a molecular fingerprint, and used for identification. But one can go further than this; the mass spectrum of a mixture of substances can be analysed for the relative abundance of the components of the mixture, that is quantitative analysis of mixtures can be carried out. A simple example is shown in Fig. 4, where the mass spectra of methane and of ethane are shown, together with the mass spectrum of an equimolar mixture of the two. In a diagram such as this the heights of the lines at different mass numbers represent the ease of production of the given species. The most abundant peaks are at 16 in methane (top spectrum), namely, the parent peak, and 28 in ethane (middle spectrum), namely, a fragment peak. The results for the mixture (bottom spectrum) would enable us to conclude that it contained

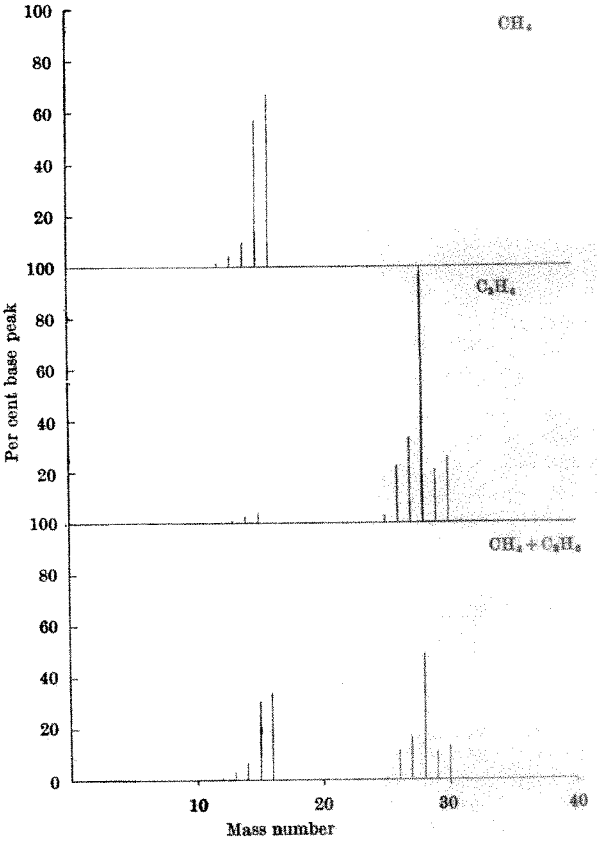

Fig. 4. The mass spectra of methane, ethane and an equimolar mixture of the two substances

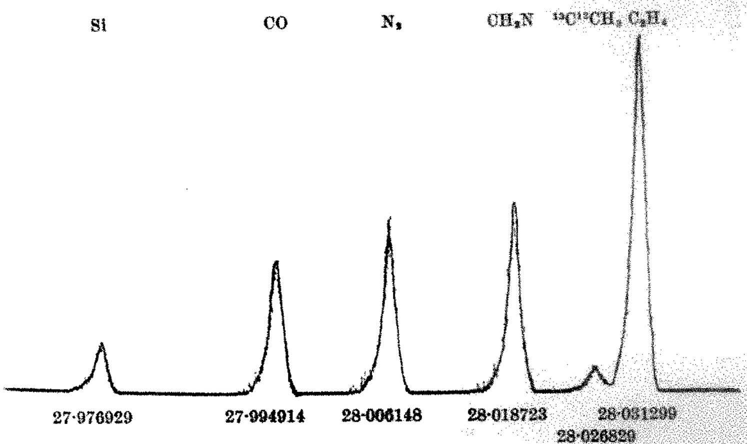

Fig. 5. A sextuplet at mass number 28 resolved on the A.E.I. *MS*9 mass spectrometer

equal amounts of methane and ethane. Problems of this sort, which were particularly relevant to the oil industry, resulted in the first commercially produced mass spectrometers. This aspect of mass spectrometry we hope to utilize in our investigations of reaction mechanisms, in particular in the identification of the products of reaction.

The mass number of an ion or a fragment is not sufficient to identify the atomic composition of the fragment. For consider the case of mass number 28. This could arise from Si, CO, N_2, CH_2N, $^{13}C^{12}CH_3$ or C_2H_4, the mass numbers of hydrogen, carbon, nitrogen, oxygen and silicon being 1, 12 (or 13), 14, 16 and 28 respectively. However, the atomic weights vary slightly from whole numbers as shown in Table 2.

Table 2. Some Atomic Weights

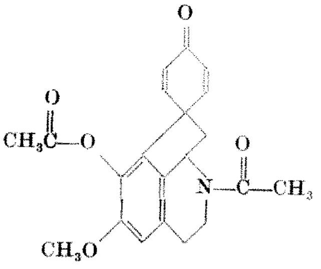
Element	Atomic wt.
H	1·007825
C	12·000000
	13·003355
N	14·003074
O	15·994914
Si	27·976929

Such a sextuplet resolved on the *MS*9 mass spectrometer is shown in Fig. 5. If mass measurements can be made to a sufficiently high degree of accuracy, the atomic composition of the ion or fragment may be determined. This aspect has immediate application to the investigation of molecular structure, since in one step the molecular formulæ of a given compound can be unambiguously determined. Thus in our examination of a compound isolated from an East African plant and containing only carbon, hydrogen and oxygen, we found the molecular weight to be 412·224 ± 0·002. Examination of possible formulæ (about thirty in all, some of which are shown in Table 3) showed it to have the composition $C_{25}H_{32}O_5$.

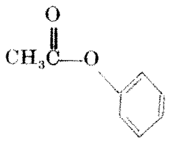
Table 3. Some Possible Formulæ of a Compound of Mass No. 412

$C_{24}H_{28}O_6$	412·189
$C_{25}H_{32}O_5$	412·225
$C_{26}H_{36}O_4$	412·261
$C_{27}H_{40}O_3$	412·283
$C_{27}H_{56}O_2$	412·428
observed	412·224

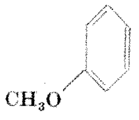
The next aspect of mass spectrometry I wish to discuss is the determination of the structure of a given molecule from its fragmentation pattern. This is, of course, a problem of much greater difficulty, due to the mass of information afforded by the many lines in the mass spectrum. However, as an example, let us look at the inverse problem, namely, the interpretation of the mass spectrum on the basis of an established formula. Thus diacetyl crotonosine, a substance isolated from a West Indian plant, was shown to have the structure *A* by Profs. Barton, Hayes *et al.* In order to simplify the problem, spectra of the model compounds related to *A*, namely, phenyl acetate (*B*), anisole (*C*) and *N*-acetyl piperidine (*D*), were run, and are shown in Fig. 6.



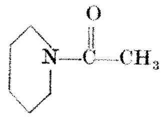
A, $C_{21}H_{21}O_5N$, 367



B



C



D

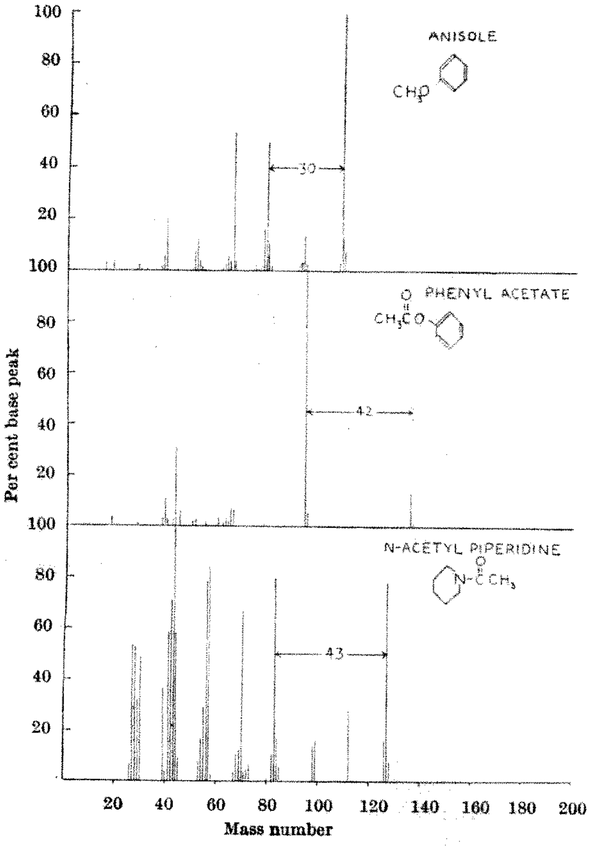


Fig 6. The mass spectra of anisole, phenyl acetate and *N*-acetyl piperidine

Large peaks occur in these compounds due to the loss of ketene (mass 42), formaldehyde (mass 30) and the acetyl radical (mass 43) respectively. In diacetyl crotonosine, peaks at 337 ($C_2H_{19}O_4N$), 325 ($C_{19}H_{17}O_4N$) and 324 ($C_{19}H_{16}O_4N$) can be interpreted as due to losses of formaldehyde, ketene and the acetyl radical respectively. The interpretation of the many remaining lines will have to await another occasion.

There is one further aspect of mass spectrometry that we are investigating, namely, the phenomenon of metastable peaks. These arise from processes of the type:

$$M_1^+ \rightarrow M_2^+ + M_3$$

for example:

$$\{C_2H_5Cl\}^+ \rightarrow \{C_2H_4\}^+ + HCl$$
$$\{C_6H_5OCH_3\}^+ \rightarrow \{C_6H_6\}^+ + CH_2O$$

which occur after the ion has been accelerated but before it enters the magnetic analyser. Now the mass spectrometer only sees those metastable reactions that occur in the region of the entrance to the magnetic analyser. A simple relation exists between the masses of the original and of the offspring ions, and the non-integral mass at which the metastable peaks occur. It is:

$$m^* = \frac{m_2^2}{m_1}$$

where m_1 and m_2 are the masses of the original and offspring ions, and m^* is the mass at which the metastable peak occurs. Metastable peaks may be used to confirm a postulated fragmentation. In this way the production of olefines from alkyl halides and of formaldehyde from anisole can be shown to have arisen, at least in part, by electron bombardment and not by thermal decomposition. The metastable peak in anisole due to the elimination of formaldehyde is shown in Fig. 7. The characteristic

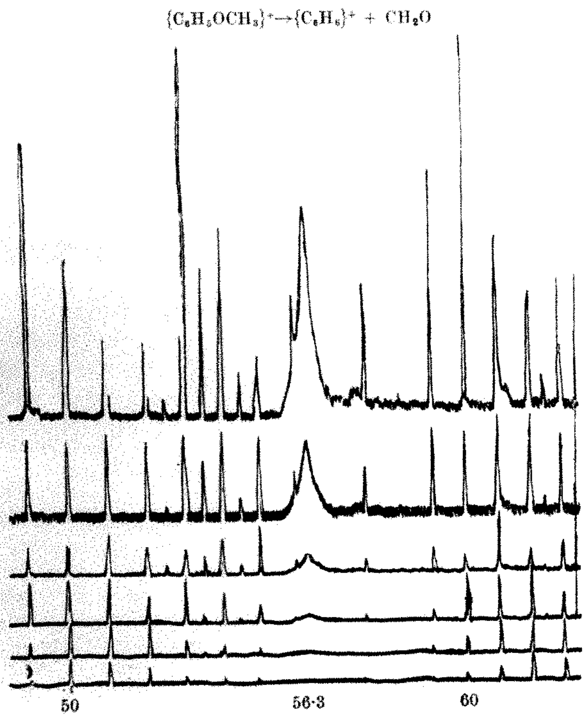

Fig. 7. A metastable peak in anisole

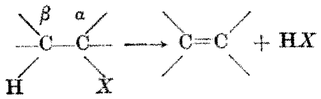
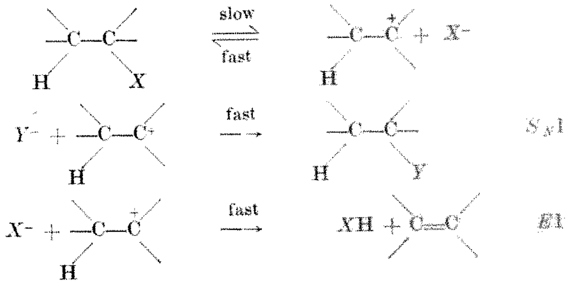
width of such peaks compared with the normal peaks is apparent, the width in this case extending over more than one mass number. Further, by observing the variation of the intensity of the metastable peak under various conditions, an estimate may be made of the rate of the unimolecular reaction giving rise to it. The half-lives of such processes are of the order of a microsecond.

This leads me back to the other area of our researches, namely, the kinetics of gas-phase reactions. The essential problem here is the prediction of the rate at which a reaction occurs in terms of some previously known properties of the atoms or molecules of the reactants. As we have already seen, the problem may be tackled at the three different levels, which we have called the mathematical, the physical and the chemical. We have applied the chemical method to homogeneous unimolecular gas-phase elimination reactions of alkyl halides:



yielding an olefine and a hydrogen halide (X being Cl, Br or I). The method is to take a parent molecule, namely, the ethyl halide, and determine the effect of substitutions at the α- and β-carbon atoms on the rate of elimination. The basic method has been used to great effect by organic chemists and in particular by Prof. Ingold and the late Prof. Hughes, in their investigation of reactions in solution. It was perhaps understandable, although still surprising, that Dr. Thomas and I were led to postulate an analogy between the gas-phase elimination reaction and reactions occurring in solution in a polar solvent by the unimolecular mechanism. Understandable because we were working in a department which had devoted so much of its energies towards an interpretation of reactions in solution. Surprising because, while the solution reactions occur at temperatures between 0° and 100° C, the gas-phase reactions take place between 200° and 450° C.

The solution reactions have been established as proceeding through a slow, rate-controlling ionization. Thus the following scheme holds for either substitution (S_N1) or elimination ($E1$). On the basis of these mechanisms, it follows that the rate of the unimolecular reaction will be increased by the attachment of electron-repelling groups at the α-carbon atom (and to a lesser extent at the β-carbon atoms) and decreased by the corresponding attachment of electron-attracting groups. Or, put in another way, factors which tend to stabilize the carbonium ion will also tend to speed up reactions by the unimolecular mechanism.



The evidence on which the analogy was based, namely, the effect of substitution on rates of reaction, is shown in Table 4. In the case of the chlorides the data are in the main taken from the work of Prof. Barton, Dr. Howlett *et al.*, while that for the bromides and iodides has mainly been obtained in this Department. It might be said in passing that, although only rate sequences are used in Table 4, the investigations have usually led to the complete temperature-dependence of the rate constant, through the Arrhenius equation:

Table 4. EVIDENCE FOR THE ANALOGY BETWEEN *Eg* AND *El*

1 $(CH_3)_3CX \gg (CH_3)_2CHX \gg CH_3CH_2X$ $X = Cl, Br, I$
2 $(CH_3)_3CCX(CH_3)_2 > (CH_3)_2CHCX(CH_3)_2 > CH_3CH_2CHX(CH_3)_2$
$CH_3CX(CH_3)_2$ $X = Cl$
$(CH_3)_2CHCH_2X > CH_3CH_2CH_2X > CH_3CH_2X$ $X = Cl, Br$
3 $CH_3CCl_3 > CH_3CHCl_2 > CH_3CH_2Cl > CH_2ClCH_2Cl$
$CH_3CHBr_2 > CH_3CH_2Br > CH_2BrCH_2Br$
4 $C_6H_5CH_2CH_2X \sim CH_3CH_2X$; $C_6H_5CHXCH_3 \sim (CH_3)_3CX$ $X = Cl, Br$
5 p-F–$C_6H_4CHClCH_3 > C_6H_5CHClCH_3 > p$-Cl–$C_6H_4CHClCH_3$
6 $CH_2=CHCHClCH_3 \sim CH_3CHClCH_3$
$CH_2=CHCH_2CHBrCH_3 \sim CH_3CH_2CHBrCH_3$
7 $CH_3OCHClCH_3 >>> CH_3CH_2X$
8 Wagner–Meerwein rearrangements

$$k = A \exp(-E/RT)$$

both A and E being determined for the reactions. It is found that the log A values are distributed about a value of 13·5 in an approximately Gaussian fashion. Thus the variations in activation energy are the major cause of variations in rate of elimination throughout a series of related compounds. This justifies the use of either relative rates or of activation energies in an attempt to correlate the effect of substitution on the rates of reaction. The striking feature of Table 4 is that the rate sequences shown are just those which have long been established as characteristic of reactions proceeding by the unimolecular mechanism in a polar solvent. This suggests that the activation energies for gas-phase elimination should be related to the heterolytic bond dissociation energies $D(R^+X^-)$ of the R–X bonds: and this provides a link between our two major areas of interest, gas-phase kinetics and mass spectrometry. For we have already seen how heterolytic bond dissociation energies can be obtained using mass-spectrometric techniques. On the basis of values of appearance potentials obtained from the literature, the plot of the energy of activation for elimination against the heterolytic bond dissociation energies is shown in Fig. 8. It will be seen that a nearly linear relationship exists between the two quantities. We are at present engaged in extending the range of appearance potentials (and hence heterolytic bond dissociation energies) so that the correlation with activation energies may be further tested.

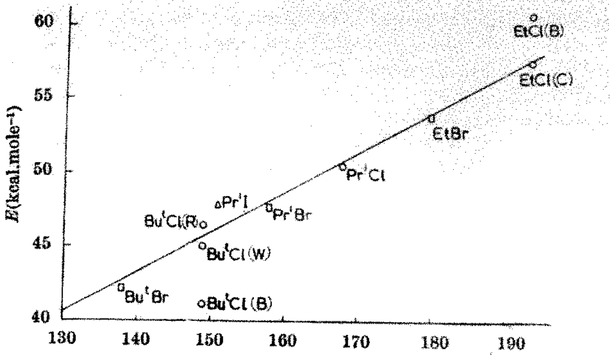


Fig. 8. Relation between the activation energies for gas-phase elimination and the heterolytic bond dissociation energies

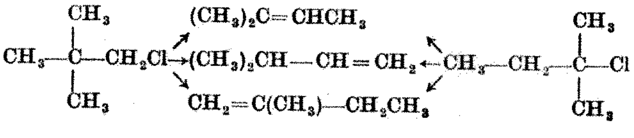
There is one further aspect of Table 4 that I would like to mention in greater detail, namely, observation of Wagner–Meerwein rearrangements in the gas-phase. The first case reported was that of neopentyl chloride, in which it was shown that the major route of pyrolysis of this compound was a homogeneous, unimolecular one, the products being those that would have been expected from *t*-pentyl chloride. This again is analogous to the results:

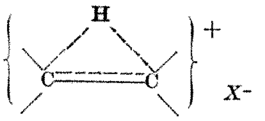


neopentyl chloride

t-pentyl chloride

observed in the examination of the solvolysis of similar compounds. During the reaction, the carbon skeleton has changed, which implies the migration of a methyl group from the β- to the α-carbon atom. Corresponding rearrangements have been observed in the gas-phase pyrolyses of bornyl and iso-bornyl chlorides, which again confirm the proposed analogy.

This then leads us to the main object of any kinetic study, namely, the molecular description of the process of reaction, or, more precisely, the assignment of a mechanism to the reaction or alternatively a physical model of the transition state. We have seen that those factors which lead to the stabilization of the carbonium ion also lead to an enhancement of the rate of gas-phase elimination. This, in turn, provides the essential clue to the mechanism. For it clearly suggests a carbonium ion character for the transition state. The essential experimental facts are in accord with the model of the transition state as an elongation, with polarization, of the $C^{\delta+}—X^{\delta-}$ bond in the sense indicated. This in turn may be represented by the formula:



on the understanding that the charge separation has not been carried to completion, and further, that the system is stabilized by polarization forces. A somewhat better than order-of-magnitude calculation shows that such a formulation cannot be ruled out on energetic grounds.

This then is the position at which we stand at present. Gas-phase elimination reactions of the type I have discussed can be understood on the basis of the postulated transition state. In addition the correlation of the solvolysis reaction in polar solvents with the gas-phase elimination reactions of the same compound can be rationalized on the basis of the gas-phase transition state presented here. What still remains is a more detailed model for the transition state which will enable more precise estimates of rates of reaction to be made. This problem is a challenging one on which we hope eventually to throw more light.

What I have tried to do is to define what I understand to be physical chemistry, to outline the areas of mass spectrometry and gas-phase kinetics which we are investigating, and to indicate the progress which has been made up to the present time. In conclusion I should like to thank those people who have helped me at various stages. First, Prof. Fawsitt and Dr. Iredale of the University of Sydney for encouraging my interest in chemistry and, secondly, the University of London for the award of an Imperial Chemical Industries fellowship. Thirdly, all my research associates, without whose help the work described here could not have been carried out. Finally, I would like to express my appreciation of the technical assistance I have at all times received, of the support I have had from this College and of the advice I have been given by colleagues past and present.

OBITUARY

Prof. J. Bartels

Prof. J. Bartels, professor of geophysics in the University of Göttingen, died on March 6.

Though deeply interested in all aspects of the physics of the Earth, and indeed much involved from time to time in seismology (results from Heligoland explosions) and meteorology (atmospheric tides and solar radiation), Bartels's life-long interest was in geomagnetism. In this discipline his early training at Potsdam Observatory under Dr. Adolph Schmidt ensured that he had the soundest possible basis on both observational practice and classical theory. One of his lasting contributions to the subject dates from that early period. He deduced from Prof. S. Chapman's analysis of the quiet day solar and lunar magnetic variations the pattern of the electric current system in the atmosphere which could produce these variations. He also became much interested in the slow secular changes in the Earth's main magnetic field and brought out clearly the regional rather than planetary nature of this phenomenon. The recognition of this later led to the cause of the isoporic foci being attributed to fluid eddies in the Earth's core.

After Potsdam, Bartels spent several periods in the Department of Terrestrial Magnetism of the Carnegie Institution of Washington. There he had direct contact with the records from various observatories which the Institution had set up in specially selected parts of the World. The abnormally large daytime amplitude of the diurnal variation at Huancayo, Peru, attracted his attention and led him with colleagues in the Institution to make a series of detailed studies. These resulted in the discovery of what has become known as the equatorial electojet, a narrow band of intensified electric current in the high atmosphere over the magnetic equator, now explicable in terms of a steep increase in conductivity where the angle of inclination of the field is small.

To follow up his long-standing interest in relationships between geomagnetic, solar and other related phenomena, Bartels needed an index of magnetic activity covering shorter intervals than the old international character figures for whole days; and, more particularly, he wanted the index to distinguish the effects of solar corpuscular radiation as shown by short-period irregular disturbance from the effects of electromagnetic wave radiation on the quiet day variation. The outcome of his work on this theme, which covered the period from before the Second World War to his later years, was the 3-h K_p index, and, more experimentally, the 15-min index Q. Thanks to its sound physical basis and the many careful investigations Bartels made to evaluate its validity and usefulness, K_p is now internationally accepted in many geophysical disciplines as an authoritative index not just for geomagnetic activity but for comparison with all effects associated with the solar corpuscular wind.

In addition to his comprehensive grasp of the physics and mathematics of geomagnetism, Bartels had an exceptional flair for handling statistics and succinctly displaying their main import. His personal contributions to the subject in a series of papers on the harmonic dial, stereograms, harmonic analysis of a single day's data, and random fluctuations and persistence in quasi-periodicities have been adopted as present-day practice in many fields. He had a special and justifiable pride in the amount of concentrated information displayed in the 'musical diagrams' which he issued regularly from Göttingen to show the sequence, every three hours, of the planetary indices, K_p, over successive rotation intervals of the Sun.

In addition to his personal research work, the results of which appeared in a long series of papers, Bartels wrote several texts on magnetic observatory practice and the theory behind it: in 1940 with S. Chapman he produced the two great volumes on geomagnetism which immediately became and still remain the definitive comprehensive text on the subject.

Since 1946 Bartels had held the joint posts of director of the Geophysical Observatory and professor of geophysics in the University of Göttingen. He took an active part in the international organizations related to his subjects, being president of the International Association of Geomagnetism and Aeronomy (1954–57), and vice-president of International Union of Geodesy and Geophysics (1957–63), and chairman of various committees and commissions related to International Geophysical Year, International Year of the Quiet Sun and, more recently, the Committee on Space Research (COSPAR). In 1953 he was awarded the Charles Chree Medal by the London Physical Society. He was awarded posthumously the Bowie Medal by the American Geophysical Union. In recent years (since the death of Prof. Regener) he had been director of the Max Planck Gesellschaft Institute of Aeronomy at Lindau.

Bartels was a kindly, friendly man with a great fund of quiet humour and with catholic tastes in music and the arts.

S. K. RUNCORN

NEWS and VIEWS

Director of the Post Office Radio Services: Mr. H. G. Lillicrap

MR. H. G. LILLICRAP has been appointed director of the Radio Services Department of the Post Office in succession to Mr. Alan Wolstencroft, who became deputy director general on August 15. Mr. Lillicrap is at present a deputy director of finance in the Accountant General's Department at the Post Office. He started work in the Research Laboratories of the General Electric Co., Ltd., at Wembley, and joined the Post Office as a probationary assistant engineer in 1936. Apart from an early spell at Exeter, he spent most of the next ten years or so at the Post Office Research Station at Dollis Hill, London, working on the design of radio transmitters and receivers. In 1947 he moved to the Radio Branch of the Engineer-in-Chief's Department, where he was concerned with frequency allocation and the technical side of broadcasting. In 1951 he became a principal in what was then the Overseas Telecommunications Department (now the External Telecommunications Executive), of which he became a deputy director in 1958. While in this work he attended numerous international conferences at Buenos Aires, in the United States, Canada, Japan and various European countries. In 1960 he became a deputy director of finance.

School of Applied Sciences in the University of Sussex: Prof. J. C. West

PROF. J. C. WEST, at present professor of electrical engineering in Queen's University of Belfast, has been appointed professor of engineering and dean of the School of Applied Sciences in the University of Sussex. Prof. West graduated at the University of Manchester in 1943 and then joined the Royal Navy Volunteer Reserve, being stationed in Northern Ireland for a period, engaged in anti-submarine warfare. He returned to the Electrical Engineering Department at Manchester in 1946, where he was appointed successively assistant lecturer, lecturer and senior lecturer. In 1958 he was appointed professor and head of the Department of Electrical Engineering in Queen's University of Belfast (*Nature*, 180, 1168; 1957), where he has been responsible for the rapid expansion of the Department. Prof. West is well known for his contributions to the analysis of non-linear servomechanisms, and for his more recent work on unconventional electrical machines. He is the author of two text-books on automatic control. As dean of the School of Applied Sciences in the new University of Sussex, Prof. West is eager to introduce undergraduate courses differing significantly from the traditional specialized subjects, and one of his first tasks is the specification of new buildings for engineers, the third time he has performed this operation.

Electrical Power Engineering in the University of Southampton: Prof. P. Hammond

MR. P. HAMMOND, Fellow and director of studies in electrical sciences in Pembroke College, Cambridge, has been appointed to the chair of electrical power engineering at the University of Southampton. Mr. Hammond was educated at Steyning Grammar School and Emmanuel College, Cambridge. He served a graduate apprenticeship in electrical and mechanical engineering with the English Electric Co., Ltd., and afterwards joined the staff of this Company as a designer of synchronous machines. He was appointed to a lectureship at Cambridge in 1949 and was later elected to a fellowship at Pembroke College. He has twice been invited to serve as visiting professor overseas: at Stanford in 1955–56 and at Kuala Lumpur in 1962–63. Mr. Hammond is the author of a number of papers and one book on electromagnetism. His research work has been largely concerned with eddy current losses in rotating machines and he has written a number of articles on the early history of electromagnetism.

Fibre Science in the University of Leeds: Prof. A. Robson

DR. A. ROBSON has been appointed professor of fibre science in the Department of Textile Industries in the University of Leeds as from September 1. After graduating from the University of Leeds in 1947, Dr. Robson worked under the late Prof. F. A. Paneth at the Londonderry Laboratories for Radiochemistry in the University of Durham, on the microanalysis of uranium. He was awarded a Ph.D. degree in 1949, and in the autumn of that year he joined the staff of the Wool Industries Research Association at Torridon, Leeds, as a senior scientific officer; latterly he has been head of the Fibre Chemistry Department. Dr. Robson's main interests have been in the application of radioisotope techniques to problems in wool chemistry. With his colleagues he has developed methods for the analysis of amino-acids and amino-acid derivatives, determined the amino-acid composition of wool and of proteins isolated from wool, and examined the distribution of sulphur in wool. The last-mentioned of these topics was supported by a grant from the United States Department of Agriculture, and led to the discovery of two new sulphur-containing amino-acids. Dr. Robson will retain responsibility for the direction of a new research project on which he and his colleagues at the Wool Industries Research Association are at present engaged, and which is also sponsored by the United States Department of Agriculture.

Medical Biochemistry in the University of Manchester : Prof. D. S. Jackson

DR. D. S. JACKSON has been appointed to be the first holder of the chair of medical biochemistry in the University of Manchester. Dr. Jackson, now aged forty-three, was educated at Farnworth Grammar School, and served from 1940 until 1946 in the Royal Air Force before entering the University of Manchester. He graduated B.Sc., with honours in chemistry, in 1949, and Ph.D. in 1954. He has been interested throughout his career in the medical applications of chemistry and biochemistry. As a research assistant in the Rheumatism Research Centre, he became concerned with the nature of collagen and reticulin, and with the response of tissues to the irritant carrageenin. In 1954–55 he was Visiting Fellow at the National Institute for Medical Research, with Prof. A. Neuberger. From 1957 until 1959 he was a research associate in biochemistry at the Harvard Medical School, and in 1959 he went to the medical school of the University of Oregon as assistant, and later associate professor. In 1962 he was appointed professor of biochemistry, and also head of the Surgical Research Laboratories in Oregon. Dr. Jackson's published work has been concerned with the proteins of connective tissue, and more recently with wound healing and tissue reaction to foreign materials and to tumours. He has also developed new approaches in the teaching of biochemistry to medical and biological students. His return to Britain, and to his own University, is welcome.

Experimental Psychology in the University of Sussex : Prof. N. S. Sutherland

THE progress of the behavioural sciences in Britain will be notably furthered by the establishment of a chair of experimental psychology at the University of Sussex and the appointment of Dr. N. S. Sutherland to it. A recruit to psychology from 'Greats', Dr. Sutherland followed this with the Oxford Final Honour School of Psychology, Philosophy and Physiology, and was afterwards elected to a fellowship by examination at Magdalen College. Encouraged by Prof. J. Z. Young in his interest in the visual discrimination mechanisms in *Octopus*, he and his colleagues have, in the past ten years, made a massive and penetrating investigation of stimulus-analysing mechanisms in both vertebrates and invertebrates. Dr. Sutherland is also well known for his contributions to human psychology, especially in the field of learning and memory. Appointed University lecturer in experimental psychology at Oxford in 1960, he was elected to an official fellowship at Merton College in 1962. He has played a large part in the development of the subject at Oxford, through a period of rapid and difficult evolution. His many friends and colleagues, not only in Britain, but also in the United States, will look forward with great interest to the development of the new department at Sussex.

1964 Guggenheim International Astronautics Award : Prof. W. O. Fenn

THE Daniel and Florence Guggenheim International Astronautics Award for 1964 has been conferred on Prof. Wallace O. Fenn, of the Department of Physiology in the University of Rochester School of Medicine and Dentistry. Dr. Fenn is well known for his work in many of the biological sciences, including respiratory problems, the mechanics of running and bodily movements, heat production of muscle, potassium and other electrolytes in muscle, and oxygen requirements of stimulated nerves. Since 1959 he has been secretary-general of the International Union of Physiological Sciences. He has been an active member on numerous committees of leading American scientific institutions, such as the National Research Council, the Research and Development Board, the National Science Foundation, and he has served at times as chairman of the Physiological Training Grant Committee and of the Physiology Study Section of the National Institutes of Health. His achievements have been widely recognized and earlier this year he received the Antonio Feltrinelli Prize for experimental medicine. The presentation of the Guggenheim International Astronautics Award will be made during the fifteenth Congress of the International Astronautical Federation, which will be held in Warsaw during September 7–12. The Award, which carries a prize of 1,000 dollars, has been made annually since 1961, but this is the first time that it has been awarded to a scientist working in the field of physiological research.

British Aviation Research

REPLYING to a question in the House of Commons on July 8, the Minister of Aviation, Mr. J. Amery, said that the Ministry's research and development establishments, in co-operation with industry, were devoting considerable effort to problems of approach and landing guidance, long-range navigation, communications, ground data handling and processing systems, the application of automation to future air traffic control systems and the use of micro-electronics techniques for civil aviation equipment. His department would also finance most of the British share in the development of the *Concord* supersonic transport aircraft, which entails the development of advanced electronic systems. Links with industry had recently been strengthened and they were very much aware of the need for the fullest dissemination of information.

Research and Development for Power

IN a written answer in the House of Commons on July 29, the Parliamentary Secretary to the Ministry of Power, Mr. J. Peyton, stated that the combined expenditure on research and development by the nationalized coal, gas and electricity industries had increased from about £6 million in 1958–59 to about £12 million in 1963–64. In conjunction with manufacturers, the National Coal Board had made significant progress in developing equipment for the widespread mechanization of coal winning, and more recently for applying remote control techniques to mining. Pioneer research by the Gas Council had led to the development of new processes which were bringing about a technological revolution in the production of gas. The Central Electricity Generating Board had expanded its central research laboratories and built new laboratories for nuclear and engineering research.

Solway Firth Barrage

IN reply to questions in the House of Commons on July 22, Mr. G. Campbell, Under-Secretary of State for Scotland, said that the proposal for a barrage in the Solway Firth was being examined jointly by the Scottish Development Group in its investigation of South-west Scotland and by the North-west England Regional Development Group. The Secretary of State for Scotland was aware of the interest of the University of Strathclyde in this problem and he was sure that it was being examined urgently. The Scottish Office was considering all representations which had been made on this subject, including the memoranda submitted by Dr. R. Drew.

The Price of Education

In reply to questions in the House of Lords on July 7, the Earl of Bessborough said that, for the present year, capital and recurrent Exchequer grants to the universities were estimated at £133 million compared with £58 million in 1959, when there were 24 university institutions, compared with the present 33. Over the same period the number of full-time students had risen from 104,000 to 125,000, and of full-time teachers from 12,000 to 15,000. These figures did not include the colleges of advanced technology and certain Scottish institutions which were achieving university status. The proportion of women students had risen from about 24 to 27 per cent. In the House of Commons on July 6, in reply to a question, the Secretary of State for Education and Science, Mr. Q. Hogg, stated that the total educational expenditure of public authorities in Great Britain, including expenditure on school meals and milk, rose from £479 million in 1952–53 to £1,277 million in 1962–63, or from 3·4 per cent to 5·1 per cent of the gross national product. In terms of constant prices the increase was estimated at about 75 per cent over the period, about half being attributable to an increase in the number of pupils and students.

British Aid to Development

In a written answer in the House of Commons on July 30, the Chief Secretary to the Treasury, Mr. J. Boyd-Carpenter, stated that the Government had announced to the United Nations Conference on Trade and Development Britain's intention of increasing her contribution to the United Nations Special Fund and to the Expanded Programme of Technical Assistance, to contribute to the African Development Bank, and to examine sympathetically the possibility of assisting other regional development banks. Britain was contributing in one form or another £7·1 million to the resources of the Inter-American Development Bank and her annual contribution to the International Development Association had been increased. At the recent meeting of Commonwealth Prime Ministers proposals were announced for a scheme of Commonwealth Development Projects, increased capital aid for higher education and an expansion of training facilities for senior administrators from developing countries in the Commonwealth. On this the Prime Minister had said in the House of Commons on July 23 that the proposals for a Commonwealth Foundation to encourage professional exchanges had been remitted to Commonwealth officials for study. He stated that he would not exclude the idea of a Foundation extending its activities to include training and exchanges of technical personnel. Much would depend on the funds available and the Foundation was devised essentially to promote professional links. Mr. Boyd-Carpenter continued that Britain would, at the third Commonwealth Education Conference at Ottawa in August, make proposals to expand and improve the Commonwealth Educational Co-operation Scheme. Recent specific bilateral commitments included provision of £52 million of economic aid for Kenya over the next three years, £51 million for Malta over the next ten years subject to satisfactory continuation of the defence arrangements, and increased aid for the Sudan. Expenditure on non-military aid in 1963–64 was £175 million and on military aid £30 million.

Japanese Aid

In the past decade Japan's gross national product has risen by about 10 per cent per annum, and in the non-Communist world only the United States, West Germany, the United Kingdom and France have a higher gross national product. With a programme of aid to developing countries of £60 million a year, she is also the fifth largest of the non-Communist donors, but a survey, *Japanese Aid*, by J. White, issued by the Overseas Development Institute, concludes that most of this is designed to help Japan's economic expansion rather than developing countries (Pp. 78. London: Overseas Development Institute, Ltd., 1964. 6*s*.). The survey reviews first the motives and objectives of Japanese aid, and then the mechanisms used and the flow of resources. It is pointed out that Japanese aid should not be judged by Western standards and attention is directed to some defects in the present system. This appears to be based on principles of selection which have little to do with the requirements of the recipients and neither enhances the programmes of other donors nor is enhanced by them. The booklet should contribute to a better understanding between Japan and the West, and Mr. White suggests that in practice Japan should be encouraged to participate to a greater extent in programmes which require detailed consultation and co-operation with other donors, and to administer a higher proportion of its aid on the basis of Government-to-Government agreements.

Infant and Neo-natal Mortality

The Office of Health Economics set up in 1962 by the Association of the British Pharmaceutical Industry has recently published a pamphlet entitled *Infants at Risk*, which gives an account of infant and neo-natal mortality, and makes a number of historical comparisons (Pp. 36. London: Office of Health Economics, 1964. 2*s*.). As is well known, infant mortality in Britain has been declining since the beginning of the twentieth century, but the rate of decline has slackened since the mid-nineteen-fifties. However, the social pattern of infant mortality has persisted almost unchanged since Edwardian days: in other words, different social groups in the community have benefited uniformly. The recent slowing down in the rate of decline means that Britain now lags behind countries such as Sweden, and a reduction of the British infant mortality rate to the Swedish level would mean a reduction of 4,000 infant deaths per annum. The report suggests that a more extensive use of ante-natal services on the part of expectant mothers might be instrumental in highlighting their present inadequacies and help in reducing the wastage immediately after birth.

Scientific Research in British Universities and Colleges, 1963–64

The 1964 edition of *Scientific Research in British Universities and Colleges* contains brief notes on scientific research in progress in British universities and colleges (including colleges of technology), and describes the nature of the projects in sufficient detail to indicate the scope of the research carried out by the various science departments and individual teams of investigators (Pp. xxv + 727. London: H.M.S.O., 1964. 35*s*. net). The social sciences and industrial administration are not included except where work in these fields normally occurs within the science faculty or technology department. Universities and colleges are listed alphabetically and under each are entered departments, and in many cases sub-departments and affiliated institutions, etc. The staff of each department are listed along with their qualifications and present fields of research. Indication is made where members of staff are affiliates of the Agricultural Research Council or Medical Research Council. The three indexes, "List of Subject Headings", "Name Index" and "Subject Index", make this publication one of the most useful guides to scientific research in British universities and colleges. The publication is issued jointly by the Department of Scientific and Industrial Research and the British Council.

Soviet Technical Literature

Tematicheskiy Plan—1964 is a complete listing in English by subject-matter of all books scheduled for publication by the Soviet Academy of Sciences in 1964 (Pp. iv + 132. London: Scientific Information Consultants, Ltd., 1964. 70*s*.; 10 dollars). Each entry gives author, title, sponsoring agency, size (in terms of printing sheets), size of edition and scheduled time of publication. Except where otherwise stated, all books are published by the Academy of Sciences. Synopses can be supplied on request at a cost of 7*s*. 6*d*. each, including postage. Some 1,255 titles are listed.

The Directorate for Scientific Affairs of the Organization for Economic Co-operation and Development has issued an index to issues 1 to 12 of the bulletin *Russian Technical Literature*, covering the period February 1960–October 1963 (Pp. 58. Paris: The Directorate for Scientific Affairs of the Organization for Economic Co-operation and Development, 1963). Entries are arranged alphabetically under author and subject, and entries relating to original contributions are differentiated. Titles of translated books are entered in the language into which they have been translated.

Bulletin of the International Computation Centre

The April issue of the *Bulletin of the International Computation Centre* in Rome contains three interesting papers concerned with the use of integrated computer systems in research and education—the latter both from the point of view of administration and of instruction. A paper by Tadatoshi Sakai, who is head of the Data Processing Section of the Bureau of Statistics, attached to the Prime Minister's Office in Japan, is of particular interest in showing the way in which the Japanese have adapted some notions on automatic programming to their IBM 705 data-processing system. In addition to the scientific papers there are a number of book reviews and notes of forthcoming conferences in the field of computation.

A Television Station in the Desert

According to a recent article in *The Lamp* (45, No. 4; Winter 1963), quarterly publication of the Standard Oil Company (New Jersey), Baghdad was the first television transmitting station to be established in the Middle East. In 1957 the Arabian American Oil Company ('Aramco'), an affiliate of Standard Oil, sponsored the setting up of the second station at Dhahran in the desert region of eastern Saudi Arabia. This was later followed by the establishment of television stations in Beirut, Cairo, Damascus, Kuwait, Abadan and Tehran. 'Channel 2 Dhahran', as it is called, can claim certain distinctions. In the first place 'Aramco Television' is probably the only social and cultural facility of its kind operated by an industrial firm. Secondly, it is the only station broadcasting entirely in Arabic. When it first came on the air the intention of the Company was to provide entertainment, information and education for 11,000 local employees and their families. "This audience is vastly outnumbered to-day by an estimated 100,000 or more viewers who can be reached by the Dhahran transmitter and a newly opened relay station sixty miles away. The number of receivers in the region has grown to about 16,000, and selling and servicing sets has provided new jobs and a brisk business for Saudi Arab merchants." The Dhahran station operates from a building situated not far from the original discovery oil-well in this desert region, the antenna being sited on the top of an old drilling rig. The station includes studio and control room for live programmes, film-processing laboratory, offices and a 'dubbing' booth; this last facility is of great importance because by means of 'dubbed-in' dialogue rendered by people who speak fluent Arabic, the characters and themes of many well-known American television films and productions are thus made available to these desert audiences. As regards programme policy, Aramco television devotes about one-third of its air-time (32 hours per week) to information and education; local events are covered by the station's own camera and sound-truck; Arabic-speaking doctors discuss hygiene, and pre- and post-natal care, among other subjects concerned with the health of the community. Although provision is made for non-Arabic viewers to enjoy imported films, by tuning their sets to a wave-length broadcasting the original soundtrack, one of the perhaps unexpected results of this enterprise has been to encourage many to learn Arabic.

New Barley Varieties in Europe

The European Brewery Convention *Report of the Barley Committee: Trials, 1962* (Pp. 138. 1964), presents the results of comparative trials of new barley varieties in twelve European countries both from the agricultural and malting points of view. From the first point of view, the trials consisted of (*a*) comparisons of the variety 'Kenia', which was regarded as the standard, with three obligatory varieties, and (*b*) local trials of some thirty additional varieties. Perhaps the major importance of these results in scientific literature is not the numerical values and assessment of specific qualities; rather is it to emphasize the complex organization required to give an overall picture of the acceptability of a new barley variety and perhaps of any agricultural crop when account has to be taken of climatic differences from country to country, climatic variations from year to year and differences in, for example, agricultural methods and susceptibility to disease in varying localities. Nevertheless, the summarized results and the country-by-country reports contain a wealth of tabulated information of a kind which would be very difficult to locate elsewhere. In addition, the *Report* includes summaries of papers presented at a joint meeting at which wider topics such as quality in malting barley, the development of barley breeding programmes and specific problems such as premature sprouting were considered. Radical new information is necessarily limited, but it will probably be helpful in similar fields to see how appreciation has grown of the value of regional agricultural experience and of objectively assessing a crop in terms which go far beyond the first consideration of yield per acre.

British Palæozoic Fossils

A genuine welcome is accorded the appearance of the Natural History Museum's publication *British Palæozoic Fossils* which completes the set of three very reasonably priced handbooks illustrating a representative selection of British fossils from the beginning of Cambrian times onwards (Pp. vi + 208 (69 plates). London: British Museum (Natural History), 1964. 12*s*. 6*d*.). Though intended primarily as an aid to the interested layman, this series also provides a wealth of readily accessible information for the specialist, and one may cite, by way of example, the synonyms given, where necessary, for the species selected for illustration. In this third handbook, an introductory chapter outlines the geological history of the British Isles during the Palæozoic Era, while subsequent sections include stratigraphical tables for each of the six systems involved, the geological distribution of the species illustrated, and brief notes on the intricacies of species nomenclature. The greater part of the book (pp. 54–191), however, is devoted to annotated illustrations of the 443 species selected to represent the Palæozoic. Having in mind the problems which must have confronted the authors, one is reluctant to criticize, but it is felt that certain improvements could have been implemented and at no extra cost. Thus, the illustrations are frequently too heavily shaded, giving insufficient contrast and consequent loss of detail, and it is unfortunate that less than 50 per cent of the species depicted are on display in the Museum. But such drawbacks are slight in comparison with the services rendered by this handbook.

Canadian Anthropology

A valuable collection of a pre-First World War field survey with excavations appears in the November 1963 issue of the *National Museum of Canada Anthropology Papers* (No. 4. *The W. B. Nickerson Survey and Excava-*

tions, 1912–15, of the Southern Manitoba Mounds Region. By Katherine H. Capes. Pp. iii + 178 (19 plates). Ottawa: Queen's Printer, 1963). This investigation utilizes the extensive field notes of Nickerson to produce a full report of his work and to show the relationship of the burial mounds of the area to those of other regions. On the basis of form, burial site and grave goods, and on distribution, the author suggests that the mounds form a north-western periphery to a great burial mound complex on the Northern Plains, evolving perhaps from Middle Woodland antecedents, and introduced into southern Manitoba by the Assiniboine.

A recent number of *Études Anthropologiques, Musée National du Canada* (No. 6, March 1964), describes the excavation of an Early Woodland site near the north bank of the St. Lawrence River (*Le Gisement de Batiscan. Notes sur des vestiges laissés par une peuplade de culture Sylvicole inférieure dans la valle du Saint-Laurient.* Par L'Abbe Rene Levesque, F. Fitz Osborne et J. V. Wright. Pp. 49 (5 plates). Ottawa: Queen's Printer, 1964). Although little organic material survived at this eroded site, diagnostic pottery and stone tools were recovered from a protected and homogeneous occupation layer. This provided one of the few culturally pure sites of Early Woodland nature in the north-east. While some quantitative analysis of the material has been attempted here, the materials thereby available would have been of greater value had the analysis been more comprehensive and the illustrations of artefacts more legible.

Index to Publications of the Bureau of American Ethnology

The Bureau of American Ethnology has published an index to the first 100 numbers of its *Bulletin*, which is likely to be of immense value, even though the *Bulletins* are now well advanced in their second century (*Bulletin* No. 178: *Index to Bulletins 1–100 of the Bureau of American Ethnology*, with *Index to Contributions to N. American Ethnology, Introductions and Miscellaneous Publications.* By Biren Bonnerjea. Pp. vi + 726. Washington, D.C.: Government Printing Office, 1963. 3.50 dollars). In addition to the subject index, there are separate indexes of authors and titles, and of illustrations. For good measure, indexes of the ethnological material in three other series which are largely out of print are added, namely, *Contributions to North American Ethnology, Introductions,* and *Miscellaneous Publications.*

University News :

Leeds

Dr. G. W. Johnson has been appointed lecturer in the Department of Metallurgy. Mrs. J. Tough has been appointed lecturer in the Institute of Education.

London

The following titles have been conferred: professor of metallurgical chemistry, on Dr. C. B. Alcock, in respect of his post at the Imperial College of Science and Technology; professor of rural economy, on Dr. G. P. Wibberley, in respect of his post at Wye College; professor of histology, on Dr. F. R. Johnson, in respect of his post at the London Hospital Medical College; professor of embryology, on Dr. P. H. Spencer-Silver, in respect of his post at the Middlesex Hospital Medical School; reader in biophysics, on Mr. D. K. Hill, in respect of his post at the Postgraduate Medical School of London; reader in hæmatology, on Mr. J. G. Humble, in respect of his post at Westminster Medical School; reader in psychology, on Dr. R. J. Audley, in respect of his post at University College.

Sheffield

Prof. R. S. Waters, professor of geography in the University of Canterbury, New Zealand, has been appointed to a chair of geology.

Battersea College of Technology

Battersea College of Technology, in anticipation of the granting of university status, has conferred the title of professor on the following heads of departments: Dr. F. M. Arscott (mathematics); Dr. L. R. B. Elton (physics); Dr. V. S. Griffiths (spectroscopy and chemical physics); Dr. Z. S. Makowski (civil engineering); Dr. J. E. Salmon (chemistry); Dr. S. R. Tailby (chemical engineering). A petition is in preparation for presentation to H.M. The Queen in Council for a royal charter incorporating the University, which it is hoped may be entitled the University of Surrey.

The International Institute for Conservation of Historic and Artistic Works

At the annual general meeting of the International Institute for Conservation of Historic and Artistic Works the following officers were elected: *President*, Dr. A. van Schendel; *Vice-President*, Mr. N. Brommelle; *Secretary-General*, Mr. N. Reid. Mr. F. I. G. Rawlins, the first secretary-general of the Institute and vice-president, was elected an Honorary Fellow of the Institute.

Announcements

The Elwell Award papers for 1964 will be presented at an ordinary meeting of the Midlands Section of the Society for Analytical Chemistry, which will be held in the University of Birmingham on September 16.

A half-day meeting of the Thin-Layer Chromatography Group of the Society for Analytical Chemistry will be held in Nottingham on September 23. Further information can be obtained from the Society for Analytical Chemistry, 14 Belgrave Square, London, S.W.1.

An international conference on "The Earth Sciences" will be held at the Massachusetts Institute of Technology during September 30–October 2. Further information can be obtained from Dr. H. G. Houghton, Department of Meteorology, Massachusetts Institute of Technology, Cambridge 39, Massachusetts.

A joint meeting of the Microchemical Methods Group and the Scottish Section of the Society for Analytical Chemistry on "Automatic Methods of Analysis" will be held in the University of Aberdeen during September 25–26. Further information can be obtained from the Society for Analytical Chemistry, 14 Belgrave Square, London, S.W.1.

The *Australian Science Index*, April 1964 (8, No. 4), contains a further 300 entries of articles published in Australian scientific and technical periodicals. The entries are classified under general; physical sciences, engineering, technology and biological sciences, agriculture; and there are subdivisions of sciences, etc. There is also an author index and a subject index.

A course of instruction in "Powder Technology", leading to a College postgraduate diploma, will be held in King's College, University of London, commencing in October, under the direction of Prof. H. E. Rose. The course, which will extend over one academic year, is designed for students having a first degree in engineering, physics, chemistry or certain other approved branches of applied science. Further information can be obtained from A. Davies, King's College, Strand, London, W.C.2. The fee for the course will be £87.

Erratum. In the communication entitled "Ammonium Production in Soil under Waterlogged Conditions as an Index of Nitrogen Availability", by S. A. Waring and Prof. J. M. Bremner, which appeared on p. 951 of the February 29 issue of *Nature*, it is stated in the twenty-first line of the second paragraph that the standard sulphuric acid used was 0·0005 N, whereas the correct figure is 0·005 N.

SCIENCE INFORMATION

A SUCCESSFUL first conference was held by the Institute of Information Scientists at Merton College, Oxford, during July 17–19, attended by 64 persons. The conference dinner on the Saturday evening was also attended by Prof. J. W. S. Pringle, representing the College, and by Mr. L. Wilson, director of Aslib (Association of Special Libraries and Information Bureaux), who proposed the toast of the Institute and spoke of the successful growth of the Institute since its inauguration in 1958, and of the courses in information science started at Northampton College of Advanced Technology, London, on the basis of the Institute's syllabus. Of these courses, the full-time, one-year postgraduate course, leading to the Diploma of the College, was the first full course in information science to be given in any country; the two-year part-time evening courses, which were started in 1961, lead to the Certificate of the Institute. The Institute now has nearly 400 members, of whom some sixty are in various countries overseas.

Of the papers presented, two concerned information services direct to management. Miss P. H. Cutting outlined the work at Messrs. Urwick, Orr and Partners, where she is information officer, and Mr. S. J. Batchelder described the work of the information department of the Leeds Incorporated Chamber of Commerce, of which he is the secretary. The wide scope and extent of the services provided at Leeds were of great interest, and indicated that many firms were finding that the Chamber of Commerce could provide answers to technical as well as economic questions. Mr. Batchelder remarked, however, that there were still many small firms which had not yet realized the value of obtaining information to improve their productivity. This is a problem which the Department of Scientific and Industrial Research and other bodies have been attacking for many years.

An interesting point of view, provoking much discussion, was put forward by Dr. F. J. Wallace, senior research engineer at the Pressed Steel Co., Ltd., Cowley; he suggested that a research worker, especially an engineer, would prefer not to be given too much information early in the start of a new project. He would want to work with a general picture of the problem, and would welcome some basic data, but then needed a period in which to develop his own ideas before again seeking the services of an information department for the provision of detailed literature on specific points which he could then select. In the discussion, it was suggested that the engineer's outlook was, perhaps, always of a more practical and less theoretical nature and, therefore, different from that of, say, a chemist who generally required the full literature in advance of a project. The differences in the information requirements of workers in different subject fields would appear to deserve further investigation.

A paper entitled "Information work in A.D. 2000" was given by Mr. J. Farradane, the honorary secretary of the Institute and Senior Research Fellow (also course organizer) at Northampton College. This was a necessarily fanciful presentation of serious considerations of possible developments of present trends in information science within the next fifty years. He considered in particular the necessity for control of scientific publications by channelling better research work into a limited number of 'official' organs which would be reviewed, abstracted and indexed in large regional information centres; all other literature, especially trade literature, would receive secondary consideration or be ignored for the record. Abstracting would have to give place to reviews of groups of papers at a time. (In discussion, Miss I. M. Slade suggested that special regional applied science and technology centres would also be needed, and could deal with their appropriate literature.) He also suggested that mechanized storage and retrieval would never be satisfactorily performed by present types of computers, which were appropriate for handling data, but not linguistic information, and that machines based on a closer approximation to the working of the human brain would have to be developed. Close liaison between such centres and industrial and other information departments (the latter feeding back information) was also considered important.

Mr. J. S. Rippon (information officer, Metal Box Co., Ltd.) gave a detailed survey of the extent to which information services could relieve research workers of the need to undertake their own literature searches. Although the research worker must clearly undertake adequate personal reading, and make his own decisions, the information department provided an essential service in view of the complexities of the literature problem and could do useful pre-evaluation of the material found. It was important that management, and research and development personnel, should appreciate the full scope of possible services which could be provided by an efficient service.

The problems of foreign literature, and especially those of technical translation and its cost, were considered by Mr. F. Liebesny (intelligence officer, British Aluminium Co., Ltd.). Since literature written in English is now only little more than half the total, with Russian now in second place, the need for skills in reading languages and for accurate translation was rapidly increasing; the exacting qualities required for good work were not common. He suggested that the only satisfactory course, in the long run, was for children to be taught foreign languages as a regular cultural necessity from an early age. The technical complexities were such that it was doubtful whether mechanical translation, even with pre- and post-editing, would ever be an economic possibility, or even feasible.

Finally, Mr. J. Blackwell (B. H. Blackwell Ltd.) and Mr. C. W. Hanson (head of research, Aslib) discussed the need for a new effort in publicizing the value of information work (and the work of the Institute). Mr. Blackwell suggested that the matter should now be put in the hands of professional publicity experts so that the subject could, in particular, be brought convincingly to the attention of management. Mr. Hanson pointed out that, as with research, it was difficult to give evidence of the direct economic value of information services; cases which might show convincing evidence were often related to confidential matters and could thus not be published. Adequate information was necessary in order to keep up to date and abreast of competition. Researches carried out at Aslib had indicated the probable extent of wasted effort due to lack of adequate information in support of research, and this waste was considerable. He therefore supported the policy of increased publicity.

The conference provided a demonstration of the growing importance of information work since the Second World War and the consolidation of the profession of information scientist. It is expected that the full *Proceedings* will be published in the autumn.

J. FARRADANE

NOMENCLATURE OF MULTIPLE ENZYME FORMS

SINCE the original demonstration that some enzymes may exist in a number of different forms in the same species or the same tissue, a considerable literature has accumulated on the topic. There has been no unanimity in these papers on the method of identifying a particular form, as Wieme[1] has pointed out. In a later note, King and Thompson[2] stated that the specific question of the numbering of isoenzymes which have been separated by electrophoresis had been referred to the Standing Committee on Enzymes and the International Commission of Editors of Biochemical Journals. The Enzyme Commission in its report[3] had made no recommendation about multiple enzyme forms, and the International Union of Biochemistry, when it dissolved the Enzyme Commission and set up the Standing Committee on Enzymes[4], also set up a Sub-committee on Isoenzymes composed of the late E. J. King, C. L. Markert, R. J. Wieme, F. Wroblewski and E. C. Webb. After the death of E. J. King, N. O. Kaplan was appointed to the Sub-committee by the Bureau of International Union of Biochemistry. This Sub-committee reached certain decisions which have been approved by the Standing Committee on Enzymes and are set out here.

Multiple enzyme forms may be distinguished from one another by any of several means, for example, electrophoresis, chromatography, salt fractionation, ultracentrifugation, immunochemistry and reaction kinetics. The electrophoretic method has been most commonly used, particularly in clinical laboratories, and numbering systems which have been utilized have usually related to electrophoretic separation. Unfortunately, two quite different systems have been used; it is now recommended that:

"When multiple forms of an enzyme are identified by electrophoretic separation, they should be given consecutive numbers, the form having the highest mobility towards the anode being numbered one".

This system is in conformity with that universally used for the fractions obtained by electrophoresis of serum proteins.

Such numbering systems are probably to be regarded as temporary expedients until information is available about the chemical differences between the various forms. If the molecules of the different forms vary in the nature and arrangements of protein sub-units, a nomenclature should be used analogous to that which has been successfully used in the field of hæmoglobin chemistry.

The Sub-committee also considered the question of a suitable word to be used to describe multiple enzyme forms. Markert and Møller[5] originally proposed "the term *isozyme* to describe the different molecular forms in which proteins may exist with the same enzymatic specificity". Since then the forms *iso-enzyme* or *isoenzyme* have also been widely used, and the term has been limited to multiple forms in a single species. The majority of the Sub-committee felt that the latter forms were preferable as being more logical and in line with such terms as *isotope*.

It is, therefore, recommended that:

"Multiple enzyme forms in a single species should be known as *isoenzymes*, although since either form is readily intelligible this recommendation is not to be interpreted as excluding the use of 'isozyme' if any individual author prefers it".

EDWIN C. WEBB

THE MEDICAL RESEARCH COUNCIL

THE latest report of the Medical Research Council* again impresses us, as previous reports have done, by the immense range and outstandingly practical value of the research work supported by the Council and carried out in numerous research centres in Britain and abroad. Established in 1913 as the Medical Research Committee, the Council was created and was granted its Royal Charter in 1920, and in November 1963 it celebrated its fiftieth anniversary at a dinner at the Goldsmiths Hall, at which the guest of honour was the Minister for Science. The Council re-formulated in its report for 1960–61 its concept of the part it should play, that is, "to watch over the whole field of medical and related biological research, so as to foresee the needs and opportunities: to give support to any promising research in these fields irrespective of the agent concerned; to work in partnership with the universities and professions on the one hand, and the various departments of Government on the other, so that new knowledge may be made available as the need arises". Following this aim, the Council has supported research in two main ways: by employing its own staff in its own institutes and research units; and by helping the work of the staffs of other agencies such as universities or hospitals by means of temporary or block research grants or by setting up research groups. Thus, apart from the National Institute for Medical Research at Hampstead, the Council has established 72 research units, of which four are abroad (one each in Gambia and Uganda and two in Jamaica) (see also *Nature*, **200**, 1039; 1963). During 1962–63 the Council set up three new research units: one, now in Cambridge, is investigating abnormal hæmoglobins: another, at Oxford, is investigating the psychological aspects of speech and language; while another, at the Imperial College of Science and Technology, is investigating metabolic reactions in the tissues of higher animals and in micro-organisms. Five other new research groups are devoted to biomechanics, megaloblastic anæmia, respiration and energy metabolism in the new-born, the immunology of certain skin diseases, and genetic problems in orthopædic conditions such as club foot and congenital dislocation of the hip. During the year 1962–63, research workers at the Medical Research Council published 4,730 papers in various scientific journals.

After paying a well-deserved tribute to the Rockefeller Foundation and its work, this report records the value the Council places on its happy relationships with this Foundation and its gratitude for the help given by the Foundation to medical research in the United Kingdom, especially by its establishment of the Rockefeller travelling fellowships between the years 1923 and 1963. Since their foundation, 203 fellowships have been awarded and many of the Fellows have become university officers of high rank. In 1964 the fellowships will be discontinued, but the Council will now award travelling fellowships of its own to replace the Rockefeller awards.

* Committee of Privy Council for Medical Research, Report of the Medical Research Council for the year 1962–1963. Pp. vii + 280 + 3 plates. (Cmnd. 2382.) (London: H.M.S.O., 1964.) 16*s*. 6*d*. net.

The report refers to the much-publicized subject of "Investigations on Human Subjects", and in this report 4½ pages are devoted to an important statement of the Council's views as to the considerations which should govern medical men who may propose for one reason or another to carry out experiments on human volunteers in order to advance beneficent knowledge. This statement will be heartily welcomed by all medical men and research workers. Important also and of great interest to all medical men and biologists is the section of the report entitled "Some Aspects of Medical Research", which will be published separately together with the Council's statement on responsibility in investigations on human subjects, under the title *Current Medical Research* (H.M.S.O. 4*s*. 6*d*.). As most readers will know, this section has been a feature of previous reports and has been published separately under the same title. This year it discusses the theoretical basis of organ transplantation; chromosome damage in man following exposure to ionizing radiations; clinical genetics and its applications (illustrated by 3 plates); recent studies on the control of ovarian function; microbial drug resistance; the chemotherapy of cancer; protein turnover in the central nervous system; and epidemiological research in psychiatry. All these articles have valuable bibliographies.

The rest of the report is devoted to an extensive summary of all the research work being done under the auspices of the Council, with details of the personnel employed in various capacities and indexes of their names and of the subjects they are working on and of the establishments in which they are working.

Taken as a whole, the report provides a valuable epitome of the main trends of the medical and biological research now being done not only in Britain but also in the tropics and elsewhere. The Council's work is unique. It deserves the widest publicity, for a nobler example could scarcely be found of the devoted co-operation of men and women of all grades of skill and experience for the benefit of their fellows all over the world.

G. LAPAGE

A HALF-CENTURY OF FRUIT RESEARCH

SINCE there have been less than forty half-centuries since the beginning of our present dating era, a jubilee provides a sufficient lapse of time over which to review progress in any field of sustained human effort. That East Malling Research Station came into being before the First World War was a major achievement, for money and effort were then but sparsely invested in the pursuit of new knowledge. The Station's first contribution to the fruit-growing industry was spectacular—the classification of rootstocks to give, for the first time, reliable, regulated production in orchards—and the name of its early director, R. G. (later Sir Ronald) Hatton, is inseparably linked with this. It was almost inevitable that subsequent contributions had to become more detailed—more intensive investigations of smaller parts of the whole problem of fruit production. Papers delivered during the three-day jubilee celebrations therefore give a unique opportunity for reviewing the work at East Malling as a practical whole*.

A true perspective was introduced at the outset in a paper by W. S. Rogers and D. W. Way, who, speaking of strawberry culture, stated bluntly "the need is for cheaper production and greater economy of labour, and the most likely contribution to this, on the cultural side, is in the use of herbicides". This conclusion followed a gratifyingly long-term review of all aspects of culture, for W. S. Rogers has been concerned with the trials for thirty-six years. R. I. C. Holliday spoke of the herbicides, of which simazine has proved the outstanding material so far for soft fruits. The work on rootstocks still continues, and W. S. Rogers discussed the features of Malling-Merton 104, 106, 111 and Malling XXV among others. Trees are also being worked 12 in. above the ground to give a 'built-in' insurance against the soil-borne fungus causing collar rot. Sufficient water is a basic need for any crop, and J. E. Goode demonstrated average increases per acre of 4 cwt. of black currants per in. of water applied as irrigation. D. W. P. Greenham, investigating problems of manuring and soil management, has also linked them with water needs. Dessert apples have not responded greatly to applications of phosphate or potassium, and after being planted for 32 years have only responded to light dressings of nitrogen during the past ten. This work seems to indicate the need for careful timing of the applications of water and nitrogen to give the maximum desired effect. The long-term nature of this work also is particularly valuable. Still on the subject of management, J. F. Wilson showed that proper composting of hop bines and trash after picking by stationary machine destroys the *Verticillium* fungus causing wilt. This is a most welcome adaptation to a modern economic tendency, and provides better facilities for checking the spread of *Verticillium* than those previously possible.

It takes a great deal of detailed research to simplify and improve measures of direct control of fungal and bacterial diseases, but there are three most welcome instances of this. *Botrytis* fruit rot of strawberries is a tantalizing disease of greatly varying severity between localities in the same season, and between seasons in the same locality. M. H. Moore has shown that much infection arises from earlier attack of the fungus during flowering, so a spray of thiram or captan then is far more effective than later. Apple scab and apple mildew are now being controlled by sprays designed to reduce infection in the spring, and *Gloeosporium* diseases in store by reducing infection in the orchard between July and September (J. E. Crosse). Spores of the *Verticillium* wilt fungus of hops are relatively short-lived in the soil (G. W. F. Sewell and J. F. Wilson). They do not attack grasses, thus suggesting measures of control by grassing down for short periods and linking with the control by composting mentioned here. Life-cycle investigations of codling moth and tortrix have also led to more effective timing of sprays against these insects, as described by G. H. L. Dicker. There are now highly efficient insecticides, but their very efficiency brought an increase of fruit-tree red spider mite which requires separate control.

Virus diseases limit fruit production greatly, and A. F. Posnette reviewed the methods of virus control—relative isolation of stocks, the planting of healthy material, the control of aphids and other vectors and the thrilling development of heat therapy. The recognition of leaf-hopper and soil nematode vectors has brought new methods of control, but the older methods of planting only virus-free stocks are still highly effective, for "trees (now ten years old) of our cherry and plum mother tree clones have yielded three times the crop produced by virus-infected trees often used for planting orchards in the past". J. T. Legg showed that degeneration of the hop can be explained by the joint attack of 'nettlehead' and 'line pattern' viruses, but here again, vigour can be maintained by planting only virus-tested stocks supplied by the Station through the Ministry of Agriculture's A-plus scheme.

* The Kent Incorporated Society for Promoting Experiments in Horticulture. Jubilee Annual Report of the East Malling Research Station, Maidstone, Kent, 1st October, 1962, to 30th September, 1963. Pp. xxx + 208. (Fifty-first year.) (East Malling, Maidstone: East Malling Research Station, 1964.) 17*s*. 6*d*.: 2.50 dollars.

R. V. Harris, in an introductory paper on hop problems, outlined, *inter alia*, the part that could be played in disease control by the breeding of resistant or tolerant varieties. There are always variations within such varieties, but P. W. Talboys concluded that "variation in response to local environmental factors will always tend to be large in varieties of intermediate resistance, but small in very sensitive or very resistant varieties". He also showed that resistance to *Verticillium* wilt depends on the more rapid completion of endodermal suberization, and the production of highly tolerant varieties is thus placed on a sure basis. East Malling has produced new varieties of black currant and a whole range of raspberries; R. L. Knight and Elizabeth Keep discussed patterns for remodelling varieties for resistance to aphids and *Botrytis* fungi, black currant varieties for new strig type and resistance to gall mite, gooseberry for spinelessness and resistance to American gooseberry mildew, and all for high yield and quality. There are also some interesting interspecific crosses.

One might perhaps predict for the future that, as the great practical work of the Station is now to reduce costs for the industry, more assessment will become necessary of the relative expenditure required for the various new operations introduced by research. There is nothing mercenary about this, for as the World wants more food, it wants it without the expenditure of undue human energy, and the scientific measure of such energy is ultimately based on its cash value. In reviewing the sustained work of the Station as a whole I have, unfortunately, omitted mention of twenty-five detailed papers, a general review and four bulletins for fruit growers which indeed occupy the bulk of the report. Apologies to the authors of these, but warmest congratulations on the Jubilee, thus fortified by an acute appreciation of the Station's work. J. GRAINGER

SCIENCE IN THE JUNIOR SCHOOL

IN the initial competition for the Guinness Awards for Science Teachers in Training, held in 1963, the first prize was gained for their joint work by two students, Sheila Stafford and David Horswill, of the City of Leeds Training College. A slightly edited version of their entry has now been published as a special Supplement to *The Science Teacher* (7, No. 7; July 1964). It needs to be appreciated that, at the time when they were producing their essay, the classroom experience of these two students was limited mainly to their periods of school practice and observation of teachers in action, so that they were drawing on their own academic studies, which included among others the writings of Susan Isaacs, J. Piaget, and Cyril Burt.

Following a trend which is gathering strength, they have broken away from the tradition that for young children nature study provides the best introduction to science. Instead, they consider that the aim should be to help boys and girls to gain confidence in scientific methods of enquiry and experiment, and train them to think methodically and logically, so that, within the scope of their abilities, they may gain an understanding of selected aspects of the world around them, in accordance with the needs of society. There should be no fixed syllabus, although, while allowing for flexibility, the course should not lack cohesion; and the driving-power should come from the children's own interests, the teacher sensing "when to follow, when to discuss, explain, teach or guide". In this way they believe the teacher can provide opportunities for progressive observation and experiment which will lead to deeper understanding and the formulation of simple, general laws—as, for example, those relating to elementary magnetism and the reflexion of light.

The essay includes sections on such topics as the help teachers can give in building up concepts, project work, and the value of class discussion; and it ends with an outline syllabus for children of seven to eleven years old. Although somewhat discursive and repetitive, it is a commendable piece of work, well in line with modern developments in the junior school; and it indicates that the scheme of Guinness Awards for Science Teachers in Training is serving a useful cause. It also highlights the need for more attention to be directed, at full research level, to a still greater cause, that of gaining a better understanding of individual attitudes, interests and abilities, in relation to science, throughout the whole of the educational period. R. WEATHERALL

INDUSTRIAL DESIGN

IN a debate in the House of Lords on June 17 Lord Peddie directed attention to the annual report of the Council of Industrial Design and referred to the recent Fielden Report on *Engineering Design*. The latter had expressed the view that Britain's share of international trade in engineering goods had been declining because, in spite of many notable successes, many British products were being outclassed in performance, reliability and sales appeal. Lord Peddie referred to the importance of raising the standards of design. He thought that design in industry was never more important than it is to-day, and he also thought it unfortunate that industrial design was mentally closely identified with art. During the past twenty years the Council of Industrial Design had played a significant part in increasing the awareness that good design was an expression of creative genius and of the importance of the whole subject. But he thought that it was necessary to increase substantially the work of the Council and to extend its activities into designs not at present covered by the Design Centre, capital goods and engineering industries. He thought a closer association would be justified between the Council and the Department of Scientific and Industrial Research. It was encouraging to see that the Royal College of Arts was now recognizing the importance of greater attention to the problem of industrial design, and Lord Peddie also referred to the proposal for a university on design and technology in northern Middlesex.

The Minister of State (Board of Trade), Lord Drumalbyn, referred briefly to the development of industrial design to put the question of design into perspective. He pointed out that the new profession of industrial designing had formally been recognized less than thirty years ago (1936) when the Royal Society of Arts founded the distinction of Royal Designer for Industry, of which there were now 48 in addition to 13 honorary foreign holders of the distinction. The Council of Industrial Design and its Scottish Committee had been formed in 1944 to promote by all practical means the improvement of design in the products of British industry, and in 1956 the Design Centre had been established at 28 Haymarket, London, S.W.1: the

Design Centre in Glasgow was opened in the following year. Small Design Centres with duplicate copies of the *Design Index* had recently been set up in Bristol, Nottingham and Manchester with financial support from local interests. The Council was trying to convince firms that it was in their interest to employ qualified designers and to give them their proper place in the managerial structure. It also sought to encourage a progressive attitude towards design among retailers and their customers and the recognition that the pressure for good design must come largely from the users and from the trade. At the present time the Council was concentrating on seeking to persuade buyers in the services, Government departments, local authorities, hotels, hospitals, offices, etc., to give serious thought to the design of what they bought. Lord Drumalbyn pointed out that a critical and well-informed public taste tone was important if Britain's manufacturers were to have well-designed goods to offer in competitive export markets. The grant to the Council in 1963 was £250,000 and this had been increased to £325,000 in the current year. In its new development of thematic exhibitions to show manufacturers how the industrial designer could be of service in designing such products as aircraft, vehicles, machine tools, scientific instruments, etc., the Council worked in close co-operation with the Federation of British Industries and the Department of Scientific and Industrial Research as well as the British Productivity Council.

Other speakers in the debate mentioned the importance of the education of the designer, particularly those working in the field of industrial design, and Viscount Eccles pointed out that scientific and technical education were proving a most powerful stimulant to better industrial design. Baroness Burton of Coventry thought that industrial design was now being given more careful consideration by many sections of the economy, but suggested that research into consumer needs was much more constructive than collecting complaints about the unsatisfactory products. Baroness Elliot of Harwood asked for some help and encouragement of craftsmen.

In replying on the debate, Lord Drumalbyn said that the point about postgraduate schools was very much in the mind of the Secretary for Education and Science, and suggestions from the Coldstream Council were being considered. He agreed that there was need for greater encouragement and improvement in the status of designers, but thought that more attention was being given to the display of craft goods than Baroness Elliot of Harwood had suggested.

VOLCANIC DUST COLLECTED AT AN ALTITUDE OF 20 KM

By DR. S. C. MOSSOP

C.S.I.R.O. Division of Radiophysics, University Grounds, Sydney

THE eruption of Mt. Agung, Bali (8° 25′ S., 115° 30′ E.), on March 17, 1963, caused the ejection of large quantities of volcanic dust to great heights in the stratosphere. Optical effects have been reported from both the southern hemisphere[1] and the northern[2]. This article deals with the concentration and size distribution of volcanic dust at an altitude of 20 km over a period of a year subsequent to the eruption. These measurements were made using techniques developed for the detection of extra-terrestrial particles, a purpose which the incursion of volcanic dust into the stratosphere effectively frustrated from April 1963 onwards.

Particles were collected at an altitude of 20 km by the use of a 'dust probe' carried by a *U*-2 aircraft of the U.S. Air Force. The collecting surfaces were electron microscope grids covered with carbon-collodion films and mounted on a 3-mm wide metal strip. This was housed in a dust-tight cover from which it could be caused to protrude for the desired time by the aircraft pilot. In this way the electron microscope grids could be exposed normal to the airstream, to collect airborne dust by impaction. Following Ranz and Wong[3], it can be shown that this system collects virtually all particles larger than $0{\cdot}2\mu$ in diameter of density 2 g/cm^3 under the exposure conditions.

Collections were made with varying durations of exposure while the aircraft was on a north-south track at longitude 145° E. The flights fall into two groups which we will designate northerly, between latitudes 15° and 35° S. and southerly, between 40° and 45° S.

The nature of particles collected by this technique prior to the eruption of Mt. Agung has been described elsewhere[4]. Typically they consisted of flattened 'rosettes' of water-soluble material of about 1μ diameter, within which were found denser water-insoluble particles of about one-tenth this diameter. The latter are thought to be mainly of extra-terrestrial origin, and to form nuclei on which the soluble material, ammonium sulphate and persulphate[5], is deposited when produced by gaseous reactions at these altitudes. The flattened, rather than shattered, nature of the sulphate particles indicates that they are not completely dry when collected. Their typical indented appearance in the electron microscope is illustrated in Fig. 1.

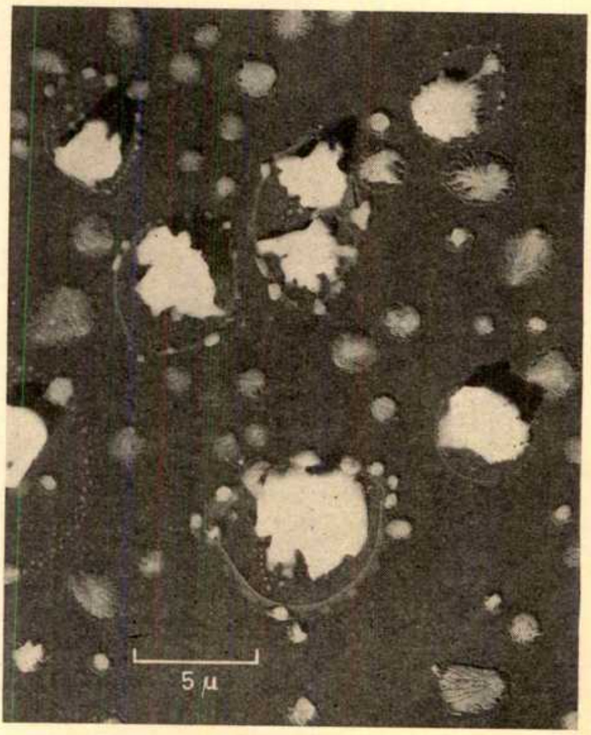

Fig. 1. Particles collected at 20 km between latitudes 44° and 40° S. on May 21, 1963, with metal shadowing. The large particles which cast an appreciable shadow are volcanic particles encased in soluble material, while the smaller flat 'rosettes' are typical of particles present at this level before the incursion of volcanic dust

Table 1. SIZE AND CONCENTRATION OF VOLCANIC PARTICLES AT 20 KM

Date	Elapsed time since eruption (days)	Latitude limits of collection (degrees south latitude)	Concentration (particles per l.)	Sampled volume (l.)	Particle dimensions (μ)		
					Maximum	Minimum	Median
11.4.63	25	15–35	8	17	3·6	0·4	1·1

18.6.63	93	45–40	84	2·6	2·4	0·2	0·65
3.7.63	108	40–44	89	2·1	1·7	0·1	0·55
30.7.63	135	41–44	102	2·6	2·0	0·1	0·45
3.12.63	261	43–44	38	1·3	0·8	0·1	0·25
7.4.64	387	41–45	35	2·0	1·0	0·1	0·2

This description applies to collections of particles made during the period January 29–March 14, 1963. Particle concentrations averaged about 30 per litre. Larger concentrations have been reported at this altitude at other times and places[5,6].

Particles of an entirely different appearance were found in a collection made on the following sampling mission on April 11, 1963, between latitudes 15° and 35° S., and in all subsequent collections at 20 km. These particles were insoluble in water, electron-dense, angular, and much larger than the non-soluble particles observed before this date. Their appearance and size, coupled with the fact that their first detection coincided with reports of vivid sunset and sunrise displays moving southward from Mt. Agung, left little doubt that the new particles were in fact volcanic dust.

As in the case of the stratospheric particles previously examined, the volcanic dust particles were covered in water-soluble material as illustrated in Fig. 1. By floating the electron microscope grids on water, specimen side uppermost, this soluble material was removed by dialysis. A typical collection of volcanic particles revealed in this way is shown in Fig. 2.

The concentration of volcanic dust in our collections was obtained by examining electron micrographs at a magnification of 7,000. The diameter of each particle was taken as the average of two dimensions at right angles to one another. In this way the size distributions shown in Figs. 3 and 4 were derived. The swept volumes corresponding to the examined area are shown in Table 1 and range from 1·3 to 83 l. depending on particle concentration. It is of interest to note that 8-μ particles were carried as far south as 41° S., and that 1-μ particles were still present at this level a year after the eruption.

At first there was no difficulty in distinguishing the volcanic dust from other insoluble stratospheric particles. From December 1963 onwards, however, many volcanic dust particles as small as 0·1μ in diameter were present, and at this size the distinguishing criterion of angularity, as against the rounded, nodular shape of non-volcanic particles, was difficult to apply with certainty. These most recent measurements may therefore underestimate

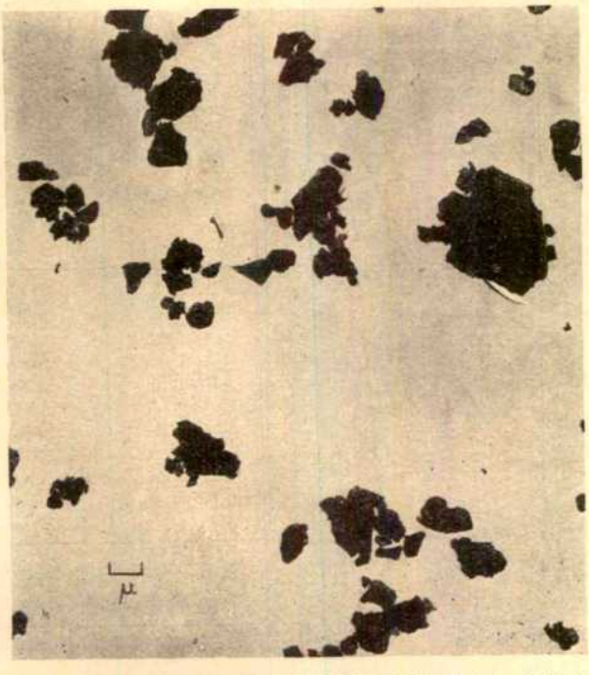

Fig. 2. Volcanic particles collected at 20 km altitude, between latitudes 15° and 21° S. on July 9, 1963. Water-soluble material has been removed by dialysis

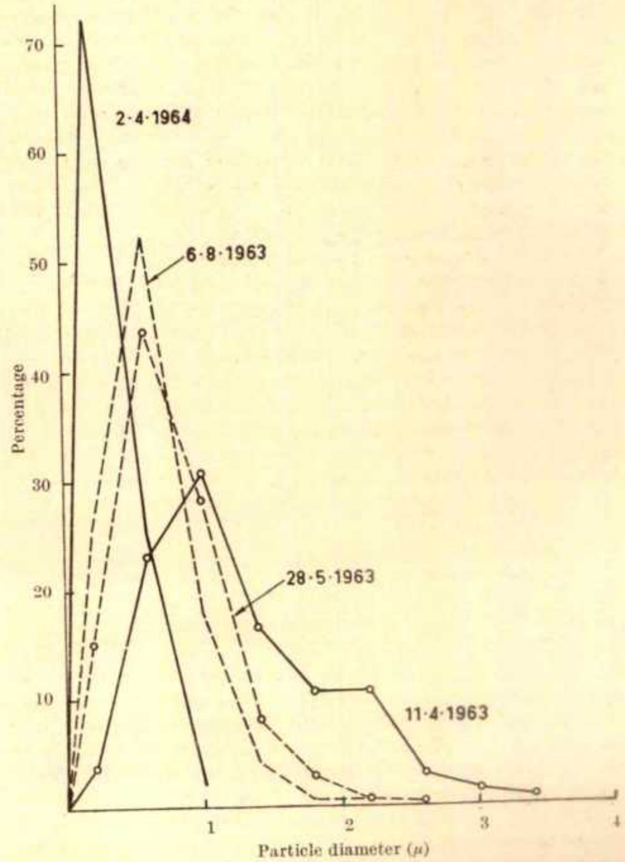

Fig. 3. Size distribution of volcanic dust particles collected at an altitude of 20 km on northerly flights (between 15° and 35° S. latitude), plotted at diameter intervals of 0·4μ

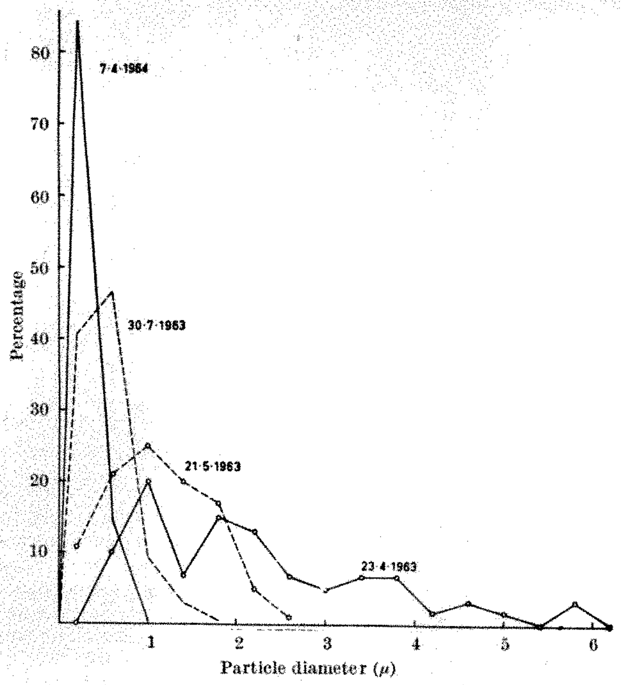

Fig. 4. Size distribution of volcanic dust particles collected at an altitude of 20 km on southerly flights (between 40° and 45° S. latitude), plotted at diameter intervals of 0·4μ

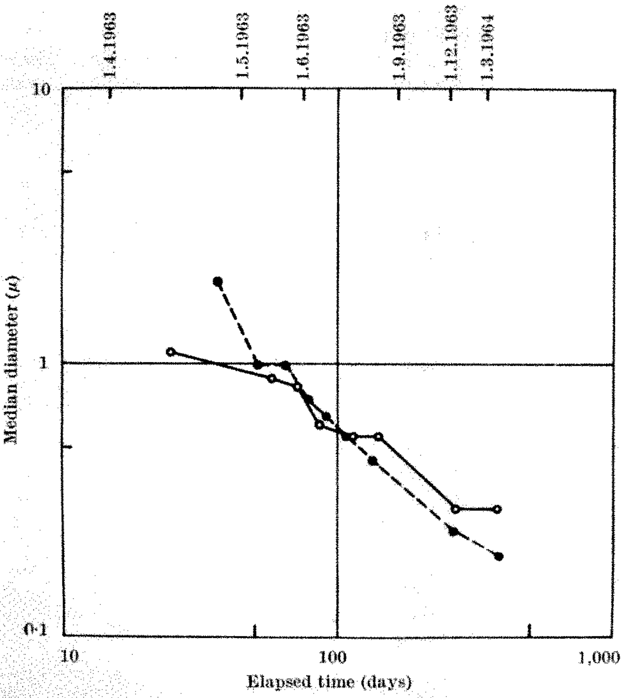

Fig. 5. Change of median diameter of volcanic dust particles with time. Full line indicates data from northerly sampling flights, broken line southerly

the concentration of the smallest volcanic particles and cause corresponding errors in the estimate of median size.

As shown in Fig. 5, the median sizes at the two sampling latitudes were very similar apart from the first southerly collection when only the largest of the southward-diffusing particles had descended to the 20 km level.

Fig. 6 shows that for a period of 80–150 days after the eruption a concentration of about 100 particles per litre prevailed at this altitude between latitudes 20° and 40° S. The mean diameter of the volcanic particles ranged from 0·8 to 0·5μ and these sizes were increased to an unknown extent by the coating of soluble material. The arrival of these high concentrations of dust was marked at Sydney (latitude 34° S.) by the disappearance of the vivid sunset and sunrise colours that had been apparent from April 14, 1963, onwards, presumably owing to the heavy attenuation of all twilight wave-lengths. These phenomena afterwards reappeared and have persisted at Sydney until June 1964 at least.

A careful search was made for spherical particles in 15 of our collections dated April 11–December 3, 1963. The total number of particles examined was of the order of 1,000 in each case. Only on one occasion, May 7, 1963, did the collected particles contain spheres and spherules.

It therefore appears that in the size range below 10μ that we are concerned with, spheres usually constituted less than 0·1 per cent of the total number of volcanic particles. This particular eruption therefore lends no support to the suggestion of Fredricksson and Martin[7] that volcanic sources provide an appreciable proportion of the black spheres and spherules found in polar ice, and in deep-sea sediments.

In the collection of May 7, 1963, there were 82 spheres and spherules, ranging from 0·5 to 5μ diameter, median value 1·7, among the total of 1,050 particles examined. As compared with this, Hodge and Wright[8] find on average that only 1·4 per cent of particles are spherules in the magnetic components of various volcanic dusts. There is therefore strong reason to believe that the spheres collected on May 7 were of extra-terrestrial origin. Their concentration at the sampled level was about two per litre.

It has previously been noted that dust particles in the stratosphere become coated with soluble material. After the incursion of dust from Mt. Agung, the quantity of this coating material seems to have increased and its

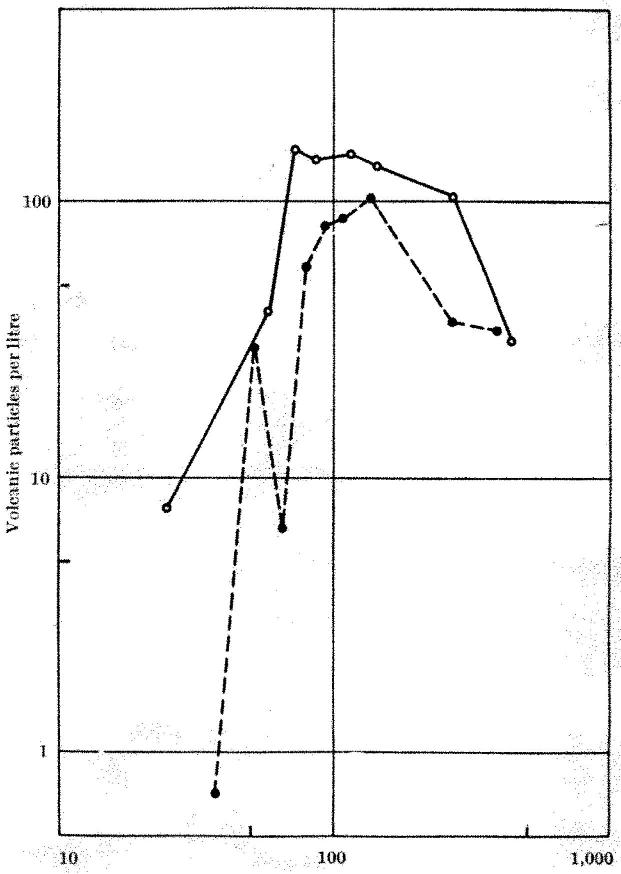

Fig. 6. Change of concentration of volcanic dust particles with time. Full line indicates data from northerly sampling flights, broken line southerly

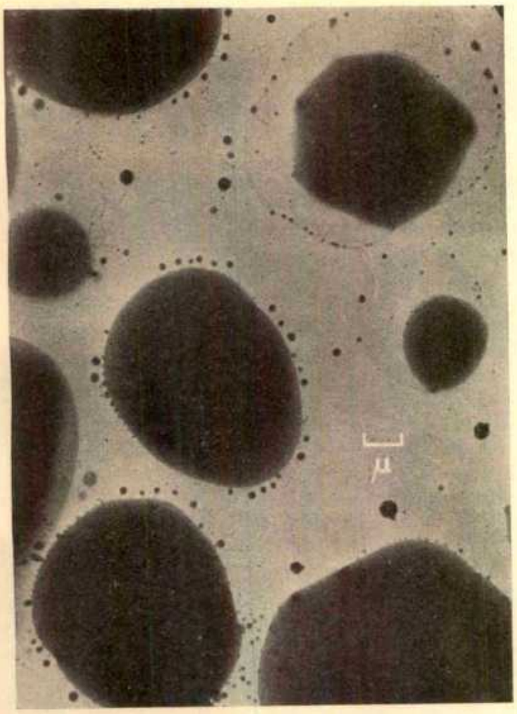

Fig. 7. Fluid particles collected at 20 km on April 7, 1964, between latitudes 41° and 45° S.

nature to have changed. This change was immediately apparent in the northerly samples. The water-soluble material is much more fluid and spreads over the collecting surface, sometimes in a continuous layer. In the case of the southerly collections this change did not become marked until June, and the 'rosette' structure of the dried sulphate particles can still be seen in the collection of May 21 (Fig. 1). In subsequent collections the coating material was much more fluid, as illustrated in Fig. 7.

This fluid material did not evaporate to any marked degree in the electron microscope vacuum but could be driven off by an intense electron beam. It caused blackening and corrosion of exposed parts of the copper electron microscope grids. The material collected on the aircraft windshield is acid to litmus paper and painfully acid to the tongue. More sophisticated tests are in preparation.

The most likely composition of this material is thought to be sulphuric acid. Reports of the Mt. Agung eruption mention the sulphurous fumes present[9] and the high sulphur content of the solid products[10]. The entry of large quantities of sulphur-bearing gases into the stratosphere might cause an excess of sulphur as compared with the ammonia present so that the action of ozone would form sulphuric acid in addition to the usual ammonium sulphates.

I thank the personnel of *O.L* 11, 4080 Strategic Reconaissance Wing, U.S. Air Force, for carrying and operating the particle-sampling apparatus on their aircraft. I also thank the Sydney University Electron Microscope Unit for electron microscopy and in particular Mr. C. D. Shorey for his assistance.

EVIDENCE FOR ASYMMETRY OF JUPITER'S VAN ALLEN BELT

By J. A. ROBERTS and M. M. KOMESAROFF

C.S.I.R.O. Division of Radiophysics, University Grounds, Sydney

MOST of the decimetric radio emission from Jupiter is believed to be synchrotron radiation from the electrons of a Van Allen belt surrounding the planet. Using the C.S.I.R.O. 210-ft. telescope at Parkes, New South Wales, we have recently examined the polarization of this radiation at wave-lengths of 6–100 cm and will submit a detailed report of the observations to *Icarus*. This article discusses two interesting features which suggest that the belt is not symmetrically disposed about the planet.

The Van Allen belt radiation is substantially linearly polarized, and Morris and Berge[1] have shown that as the planet rotates the direction of the polarization rocks through about ± 10°. Their suggested explanation of this effect, namely, a tilt of about 10° between the direction of the magnetic dipole axis and the axis of rotation of the planet, appears to be generally accepted. Several other authors have investigated this effect[2–6], but our observations, in which the linear polarization is completely determined with reasonably good signal/noise ratio at intervals of 15–45 min, serve to define the variation much more clearly and show it to possess a characteristic asymmetry. In addition they demonstrate unambiguously another feature which was inferred indirectly by others[1,5,6], namely, the beaming of the radiation, which manifests itself as a variation of the total intensity as the planet rotates.

Fig. 1 shows the variation of the total intensity as a function of the system III longitude of the central meridian. There are seen to be two maxima and minima per revolution, the minimum near longitude 200° being deeper. The curves are reasonably symmetrical about longitudes 18° and 198°.

To a first approximation this observed variation of intensity may be ascribed to the change, as the planet rotates, of the magnetic latitude of the Earth relative to a magnetic dipole centred on Jupiter. Fig. 2*a* shows the predicted variation of this latitude, when the dipole is assumed to lie in the plane of longitude 18° and 198°, and to be tilted at 10° to the rotational axis. The different depths of the two minima result from the tilt of the North rotational pole of the planet towards the Earth. The resemblance of this curve to the observed total intensity curve (Fig. 1*a*) is striking, and when, as in Fig. 2*b*, the intensities are replotted as a function of magnetic latitude it is seen that to a good approximation they are a function of the magnetic latitude alone. This is the result expected for a centred dipole.

In attempting to relate this observed beaming to the distribution of the pitch angle, α, of the electrons in the belt we have used the published computations of Thorne[7] supplemented by further calculations which he communicated to us privately. The observed beaming and the degree of polarization could be accounted for by the

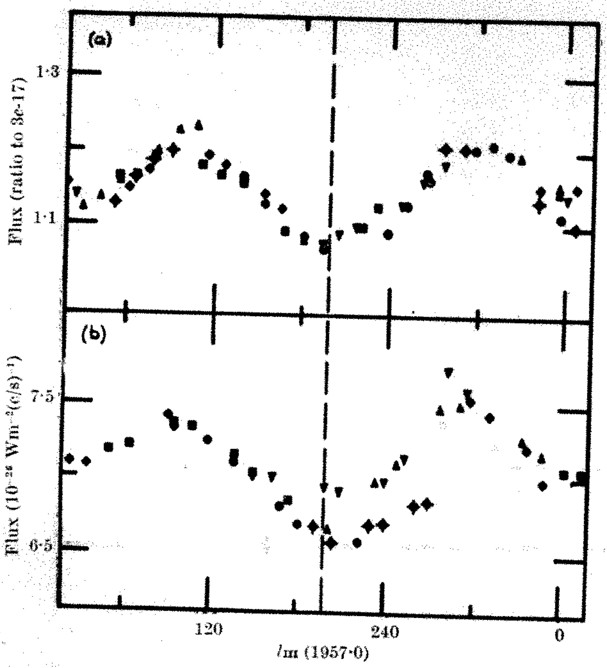

Fig. 1. Variation of total intensity of Jupiter emission with system III longitude. The intensity has been normalized to a polar semi-diameter of 22·75" arc (4.04 A.U.). The significance of the symbols is indicated in the caption to Fig. 3. (*a*) 21 cm, August 1963. (*b*) 11 cm, November 1963

superposition of two distributions of the form $\sin^9 \alpha$, in which one-quarter of the electrons were in very flat helices ($q \approx 25$) while the remainder were nearly isotropically distributed ($q \approx 2$). Such a double-humped distribution might suggest two radiation belts, an idea already proposed for other reasons by Chang and Davis[8] and Warwick[9].

Departures from the centred dipole case are apparent in Fig. 2*b* in the small but systematic displacement of the values for longitudes near 18° (shown by squares) relative to the values for longitudes near 198° (circles). This separation is not removed by changing the assumed tilt of the dipole by a few degrees, and it seems to represent a genuine asymmetry of the source. Clearer evidence for an asymmetry is provided by the variation of the direction of polarization with longitude.

The variation of the direction of polarization with planetary rotation is shown in Fig. 3. It is obvious that the direction does not vary sinusoidally. The curve is distinctly asymmetric: the downward cross-over is steeper than the upward cross-over and crosses the centre line at an earlier phase.

The effect does not appear to be transitory, as the partially incomplete curve for August–September 1962 (Fig. 3*b*) shows the same features as the curve for August 1963 (Fig. 3*a*). This comparison also shows that the rotation period of the magnetic field structure is very close to the system III period determined by the decametric radio bursts. The curves for 1962 and 1963 coincide within the accuracy of the measurements and fix the rotation period as coincident with the I.A.U.[10,11] system III within ±0·5 sec.

Although casual inspection of Fig. 3*c* suggests that the asymmetry is less marked at a wave-length of 11 cm, the differences between the 11 cm and the 21 cm data are, in fact, scarcely significant. Evidently Faraday rotation, which would be four times greater at 21 cm than at 11 cm, is not sensibly affecting the form of Fig. 3*a*.

It is easily shown that if the emitting area were completely symmetrical about an axis through the centre of the planet, but inclined at an angle ~10° to the rotational axis, the resulting variation of the direction of polarization would be a symmetrical curve and very nearly sinusoidal. Hence the observations imply some asymmetry of the belt in longitude. At the upward cross-over at longitude 17° the slope of the curve is much nearer the slope of a sinusoid of amplitude 9° or 10° than at the downward cross-over[12]. This suggests that near longitude 17° the belt may be less affected by the asymmetry. Since the total intensity curves (Fig. 1) show symmetry about a similar longitude (18° and 198°) it seems possible that a basic dipole (inclined at 9° or 10°) intersects the surface at longitude 18° in the southern hemisphere and 198° in the northern hemisphere.

The nature of the asymmetry of the belt is not clear, but it probably reflects some permanent departure of the magnetic field from the centred dipole-configuration. An asymmetrical magnetic field has already been suggested to explain the 360° (rather than 180°) periodicity in the occurrence of the decametric radio bursts[9,13–16]. If Ellis and McCulloch's[16] representation of the field as that of a centred dipole plus a local anomaly is correct, the present observations imply that the effect of the anomaly is still evident at several radii from the planet. On the other hand, Warwick[12] has shown that with a pure dipole model, but with the dipole displaced to the south, shadowing by the planet will produce qualitatively the type of asymmetry observed. Further discussion requires the extension of theoretical developments already begun[7,8,17] to provide two-dimensional distributions of the intensity and polarization for the dipole case (to test the shadowing theory), and alternatively an analysis of the non-dipolar case.

We wish to express our gratitude to the many people who have contributed to the acquisition of the data and their subsequent analysis and discussion. In particular we would like to thank Mr. K. S. Thorne and Dr. J. W. Warwick for making available their unpublished calculations, and Mr. C. S. Higgins and Mr. D. W. Orchiston

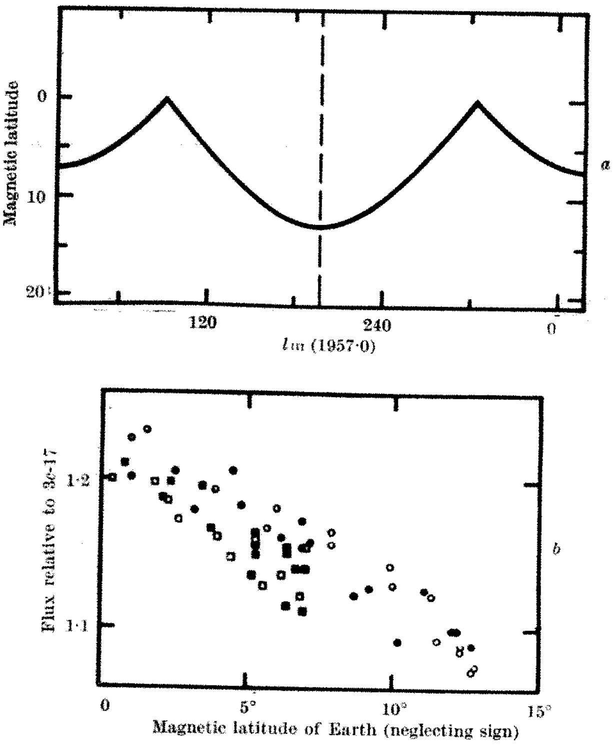

Fig. 2. *a*, The computed magnetic latitude of the Earth with respect to an assumed magnetic dipole inclined at 10° to Jupiter's rotational axis, the pole in the northern hemisphere being at $l_{\text{III}} = 198°$. A 2·9° tilt of the north rotational pole towards the Earth has been included, this being the value appropriate to the 1963 August observations. *b*, Observed total intensity at 21 cm as a function of the magnetic latitude of the Earth. This figure is derived from the data of Figs. 1*a* and 2*a*. Points corresponding to the four longitude ranges in 2*a* are distinguished thus: 18°–92° (□), 92°–198° (○), 198°–304° (●), 304°–18° (■)

STRUCTURAL IMPLICATIONS OF PALÆOMAGNETISM IN MIOCENE LAVAS OF NORTH-EASTERN OREGON, SOUTH-EASTERN WASHINGTON AND WEST-CENTRAL IDAHO

By N. D. WATKINS*

Department of Geophysics, Stanford University, Stanford, California

A PALÆOMAGNETIC survey of the Miocene lavas of south-eastern Oregon[1] was extended northwards during the summer of 1963. This communication concerns the lavas sampled in seven widely separated sections close to the sharp bend of the suspected gigantic structural feature or orocline, as proposed by Carey[2] (Figs. 1 and 3).

Waters[3] has described the lithologic variation in four of the seven sections, and has divided the Columbia River Basalt into two distinct varieties. In at least one section (Fig. 3, section *G*, Imnaha) both the younger Yakima and older Picture Gorge Basalt outcrop. The type section of the older basalt lies under the Middle to Late Miocene Mascall formation[4], and the Yakima Basalt is intercalated with Middle or late Miocene flora (*ibid.*). A few Early Pliocene lavas[5] may be present at the top of sections *E* and *F*.

More than three hundred accurately orientated cores, representing at least two cores from each lava, have been taken from a total of 154 lavas. It is probable that some of these represent repeated sampling of the same lava in different sections. The sections sampled are the largest local outcrops available, and the nature of the exposures, most of which are along the steep canyons of the Snake River and its tributaries, has in most cases enabled complete sections of successive lavas to be sampled.

Campbell and Runcorn[6] have examined the palæomagnetic properties of the Columbia River lavas, and point out that normally and reversely magnetized lavas occur in approximately equal numbers. Their results showed considerable scatter in direction of natural remanent magnetism. Lack of apparatus for removing unstable components[7] at that time no doubt contributed to this condition. Cox[8] found unusual directions of natural remanent magnetism in Eocene lavas in southern Idaho, and Irving[9] suggested that the anomalous natural remanent magnetism might be a function of tectonic rotation, since the area is still tectonically active.

The magnetic properties of each core have been determined using a spinner magnetometer and a triaxial demagnetizing apparatus[10]. Following experiments in which samples from at least four lavas in each section were subjected to progressive demagnetization in alternating magnetic fields[11], a field of 200 œ was chosen as sufficient to remove unstable components. Application of this field to each specimen resulted in a great reduction of scatter of natural remanent magnetism. Statistical analysis of the mean natural remanent magnetism in each lava has been carried out for all sections, using the methods of Fisher[12], and the results are presented in Table 1.

Table 1. STATISTICAL ANALYSIS OF NATURAL REMANENT MAGNETISM (NRM) IN EACH SECTION

Section	*N*	*D*	*I*	*R*	α95°
A	22	337° 07′	+66° 17′	21·22	6·1
B	10	334° 29′	+66° 20′	9·14	15·7
C	16	339° 08′	+73° 04′	15·08	9·2
D	30	1° 57′	+67° 47′	28·53	6·0
E	18	359° 01′	+54° 04′	17·13	8·0
F	22	0° 05′	+68° 01′	20·92	8·6
G	36	12° 45′	+61° 43′	33·28	6·9

N, No. of lavas in section; *D*, mean declination of NRM; *I*, mean inclination; *R*, resultant vector, assigning unit vector to each lava; α95°, semi-vertical angle of 95 per cent confidence cone. All reversed directions of NRM have been transposed to the northern hemisphere.

The natural remanent magnetism in all cores after removal of viscous components is presented, for two of the seven sections, in Fig. 2. The size of the unstable component in some lavas is large enough to produce pseudo-normally magnetized lavas, which Mumme[13] has described elsewhere. Removal of this unstable component to produce stable reversely magnetized lavas has resulted in the reduction of the number of the successive variations in polarity in most sections. Should

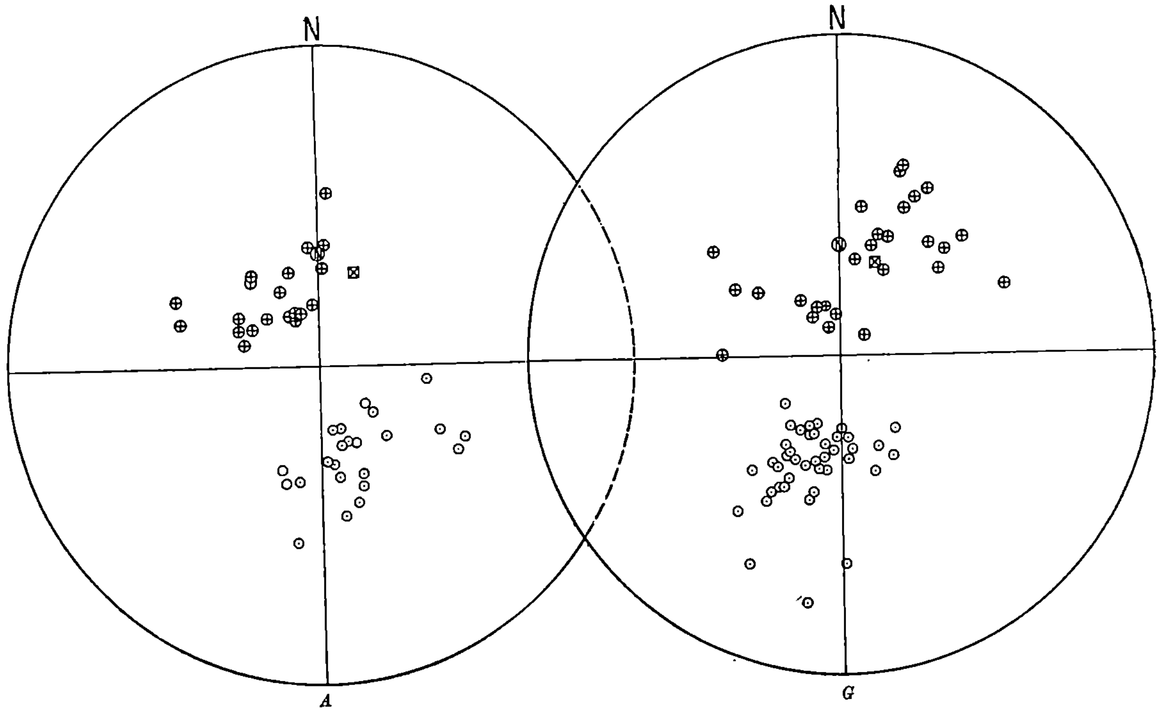

Fig. 2. Remanent magnetism in sections *A* and *G* after treatment in alternating magnetic fields. Left, Snake River; right, Imnaha. ⊕, Lower hemisphere; ○, upper hemisphere; (N), direction of geocentric dipole field; ☒, direction of present geomagnetic field

the surface geologist integrate field measurements of natural remanent magnetism[14] into stratigraphic work in this area, as Einarsson[15] and others have done elsewhere, pseudo-normally magnetized lavas would be encountered. In terms of the implied Miocene geomagnetic field this would be misleading, although there is no reason why such a lava should not be a suitable mapping unit, if the property is homogeneous in the magnetically unstable lava.

All sections feature both polarities. This polarity variation in single sections is one of several properties contrasting with properties revealed in the palæomagnetic survey of Miocene lavas of the Basin and Range area of the Columbia Plateaux to the south[1]. Here eight of ten sections possess only a single polarity in up to forty successive lavas. This difference implies a more rapid rate of extrusion in the southern region, if magnetic polarity epochs encountered are of the same order of duration as those defined in younger rocks[16]. In the present survey, the number of successive polarity variations in each section increases eastward. This may be due to the time-span of sections increasing eastwards.

The most significant result of the survey is illustrated in Fig. 3. The mean palæomagnetic declinations, determined from the mean direction of natural remanent magnetism in all lavas in each section, are plotted at each section location. The sections well to the north of the Oregon–Washington border have declinations differing from those sections to the south. (This fact is very obvious in Fig. 2.) The conditions may be caused by one of the following circumstances :

(1) The sections north and south of the Oregon–Washington border are not contemporaneous. Their different mean palæomagnetic declinations are due to the fact that insufficient time is represented by the sections to average out non-axial dipole components to the spin axis. If the polarity epochs encountered in the sections are of the same order as those defined for more recent rocks by Cox, Doell and Dalrymple[16], then the time represented would be at least five million years. The duration of the persistence of non-axial dipole conditions is fundamental in the palæomagnetic model, particularly in the application of data to inter-continental studies. The time-span required to average non-axial components to the spin axis has previously been suggested to range from ten thousand years[17] up to one million years[18].

(2) The sections north of the Oregon–Washington border are not contemporaneous with those to the south. Sufficient time is represented in the sections to average non-axial dipole components to the spin axis, but the spin axis moved considerably in Miocene items.

(3) The sections involved are roughly contemporaneous. The spin axis did not move considerably during the Miocene period, and the different declinations are the result of post-Miocene differential tectonic rotation, in the same sense as the orocline indicated in Fig. 1. Similar explanations of non-coincident palæomagnetic data are common in the literature. Wise[19] has summarized the diverse geological, geophysical and geochemical data which support a tectonic origin for the broad features of this part of the Cordillera. He does, however, point out factors contradicting the implied sense of rotation. Recently, Bodvarsson and Walker[20] have presented evidence for crustal drift in Iceland, and suggest that consideration be given to similar phenomena in the other great flood basalt areas. The enormous dyke swarms

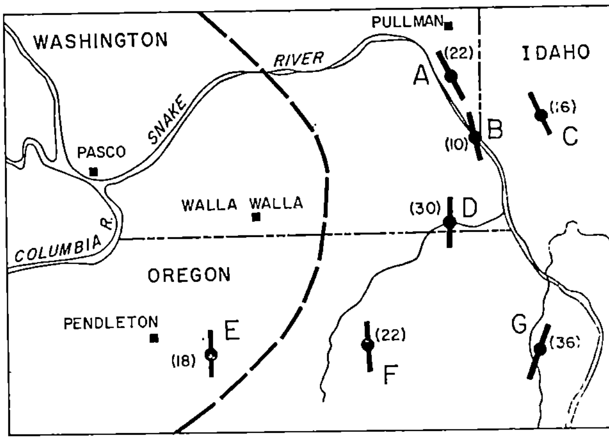

Fig. 3. Mean palæomagnetic declinations in seven sections of Miocene lavas in South-eastern Washington, North-eastern Oregon and West-central Idaho. No. in brackets is No. of lavas in each section

at Grande Ronde (in the area of section *D*) and Cornucopia (south of section *G*), described briefly by Waters[3], complement the ideas of Bodvarsson and Walker[20], who state that large-scale intrusion of dykes is a significant factor in crustal spreading in the great Icelandic lava pile. It can be stated that the palæomagnetic data are consistent with crustal spreading of the part of the Columbia Plateaux under consideration, but by no means are independent proof of the event.

Since it has been shown[1] that the Miocene geomagnetic field may be subject to apparently sudden movement, and due to the uncertainty of the time required to average non-axial dipole components to the spin axis, the possibility that ambient geomagnetic field variation may be the cause of the declination variations described in this communication must be stressed.

The ambiguity in interpretation of the observations should be resolved to a large extent by further collection in north-central Washington, and by dating of the lavas concerned in order to determine the degree of contemporaneity.

I thank Drs. A. Cox and R. Doell of the U.S. Geological Survey for the loan of equipment, and Prof. A. C. Waters of the University of California, Santa Barbara, for guidance in selection of the sections. This work was carried under a National Science Foundation administered U.S.–Japan Co-operation Programme grant to Stanford University.

RHEID AND RIGID ROTATIONS

By E. S. O'DRISCOLL

Department of Economic Geology, University of Adelaide

IN rocks deformed by rheid folding, rotational phenomena displayed by componental segregates appear to allow contradictory kinematic interpretations where the accepted sense of individual rotation cannot readily be reconciled with the proposed mechanism of environmental shearing. The subject of rheid deformation by solid laminar flow, as developed by Carey[1], provides idealized concepts that are readily susceptible of analysis through the use of laminar models where planar translations by rotational and irrotational shear are conceived. Such models as have been described[2-7] represent ideal rheid deformations in homogeneous isotropic material in terms of direct shear movement.

To facilitate geological field investigations of flow phenomena, specifically those related to the effects of rotation and stretching of dissimilar bodies embedded in a strained rheid matrix, I have recently used a combination plasti-laminar model in which to observe the behaviour of inhomogeneous material aggregates enclosed in a rheid medium that deforms by plane laminar flow resulting from experimentally controlled progressive shear deformation. These aggregates include the idealized extremes of both rigid and rheid bodies as well as intermediate anisotropic bodies that, by virtue of preferred internal slip surfaces, behave both as rigid and rheid bodies according to variations of internal shear induced in them during the controlled progress of matrix deformation. The examination of these 'rheoplex' models has disclosed some curious and seemingly paradoxical rotational and orientational qualities that are interdependent and consistent with the one superimposed deformation, although their counterparts in the field might otherwise be regarded as cogenetically incompatible.

The essential feature of the models is a rheid matrix of silicone putty (*P*, Fig. 1), which is uniformly rabbeted in the upper edge-surface (*L*, Fig. 1) of a standard laminar model. This attachment provides a direct coupling whereby transcurrent movement of the 'basement' is reproduced directly in the rheid matrix by plane laminar flow without producing visible shear planes. Within this matrix are set small bodies of various shapes and orientations. In the accompanying illustrations, rigid bodies, marked *G*, remain undeformed but free to rotate in the matrix. Rheid bodies, marked *H*, are represented by shapes engraved in the matrix, and these may be regarded as bodies of the same rheidity as the matrix and deforming with it by internal laminar flow parallel to the superimposed shear according to a direct function of the strain ellipse. Anisotropic bodies, marked *N*, are small hand-set laminar prisms, free to deform by internal laminal slip (or induced shear) which may be variously divergent from the superimposed direct shear, depending

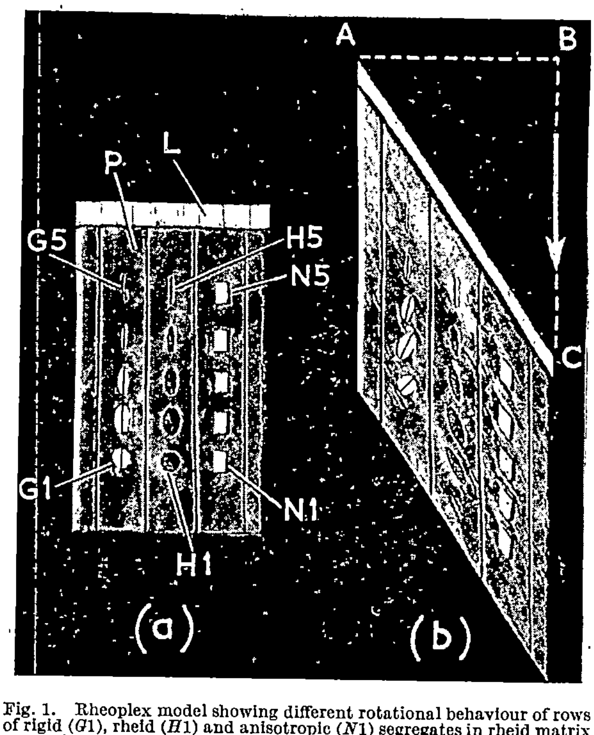

Fig. 1. Rheoplex model showing different rotational behaviour of rows of rigid (*G*1), rheid (*H*1) and anisotropic (*N*1) segregates in rheid matrix deformed by laminar flow imposed by shear parallel to rows

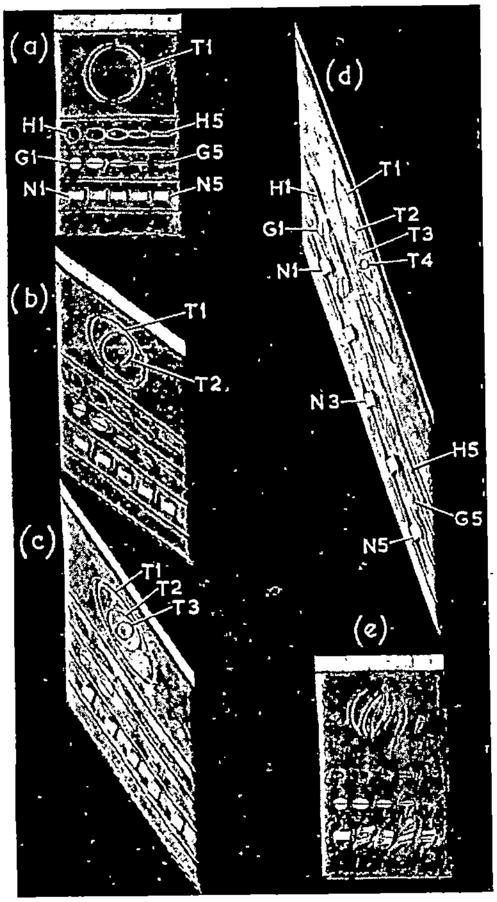

Fig. 2. Similar model to Fig. 1, except that imposed shear is perpendicular to rows of segregates. *e* shows attempted restoration by 'unshearing'

on the initial orientations of the bodies. The anisotropic *N*-bodies may be regarded as combining the behaviour of the rigid *G*-bodies and the rheid *H*-bodies depending on the divergence between the direct and the induced shear planes. By adaptation of the terms described by Wood[8], the *G*-, *H*- and *N*-bodies are called segregates, and the long axis of each segregate is called the segregate axis. Groups of segregates are called aggregates, and the long axis of distribution of such a group is called the aggregate axis.

Fig. 1*a* shows a rheoplex model containing three parallel rows of segregates embedded in a rheid matrix, *P*. The left-hand row of rigid bodies, marked *G*, contains five segregates ranging from circular (*G*1) to linear (*G*5) shape. The segregate axes of these bodies coincide with their aggregate axis, which, in turn, is parallel to the shear planes in the laminar basement, *L*. The centre row of five rheid segregates, *H*1–*H*5, has shapes and alignments identical with those of the corresponding *G*-segregates by which their respective deformational behaviour may be the more easily compared. The right-hand row contains five rectangular laminated anisotropic segregates, *N*1–*N*5, which have their segregate axes, their aggregate axis and their internal laminæ all parallel to the shear direction of the basement.

Fig. 1*b* shows the effect of a uniform superimposed right lateral shear (tan *BAC*) applied to the basement, *L*, and transmitted to the rheid matrix, *P*. It is seen that the rigid *G*-segregates rotate in a right lateral sense in sympathy with the superimposed shear, whereas the rheid *H*-segregates rotate in the opposite sense, the amount of rotation of a particular segregate in each case depending on its formal aspect ratio (length/breadth). The *N*-segregates behave in a composite manner. They deform internally by right lateral induced shear, and also rotate slightly in a right lateral sense so that their internal laminal directions assume a left-hand *en échelon* alignment along the aggregate axis. This pattern is to be compared with the left-hand *en échelon* of the rigid *G*-segregates. However, the formal long axes of the *N*-segregates now assume new diagonal positions in right-hand *en échelon* alignment, which is to be compared with the behaviour of the rheid *H*-segregates.

In the foregoing terms the remaining illustrations are largely self-explanatory. Fig. 2 shows an example where the *G*-, *H*- and *N*-segregates have their aggregate axes initially perpendicular to the superimposed shear direction. At each stage of deformation by right-hand rotational shear, a time-circle, *T*, is added to the matrix to provide a progressive deformation history, as shown by *T*1, *T*2, *T*3 and *T*4 in Fig. 2*d*. Figs. 2*a*, *b*, *c* and *d* may be compared with the right limb of a shear fold anticline during progressive deformation in which the rows of segregates define the strata, and the segregate and aggregate axes coincide initially with the bedding planes. It will be seen that for a considerable part of the deformation, the rigid *G*-segregates rotate in a left-hand sense relative to their bed, that is "in a sense just opposite of that assumed in shear folding"[9]. In the extreme deformation of Fig. 2*d*, this sense is eventually reversed. The rheid *H*-segregates behave in a contrary manner except that their sense of rotation relative to their bed does not suffer a reversal in Fig. 2*d*. Instead, the *H*-segregates are stretched to more than three times their original lengths in the plane of the bedding. It may be noted that the distance between segregates increases progressively, in contrast to Fig. 1 where the initial spacing is largely maintained during 'bedding slip'. In Figs. 2*b* and *c*, the *N*-segregates display a composite behaviour. The shear induced in them initially as left-hand internal slip in Fig. 2*c* has afterwards suffered a reversal in Fig. 2*d* in which the segregates have been restored by internal 'unshearing' to nearly their original shapes. Fig. 2*e* shows the restoration of the entire model matrix to its original shape by complete reversal of the superimposed direct shear. Both the *G*- and *H*-segregates are restored with considerable fidelity, but the *N*-segregates have undergone irreversible changes. It may also be noted in Fig. 2*e* that the matrix surface has developed a set of strain striations which supersede those in Fig. 2*c*. To the extent that these striæ or 'folds' could become fixed during deformation, a cross-fold relationship

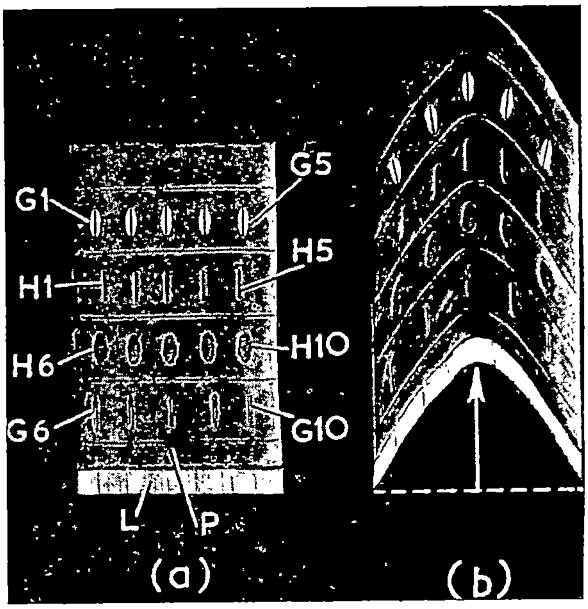

Fig. 3. Rheoplex model of anticline in which shear folding produces respectively divergent, parallel and convergent orientations in successive bands of particular segregates

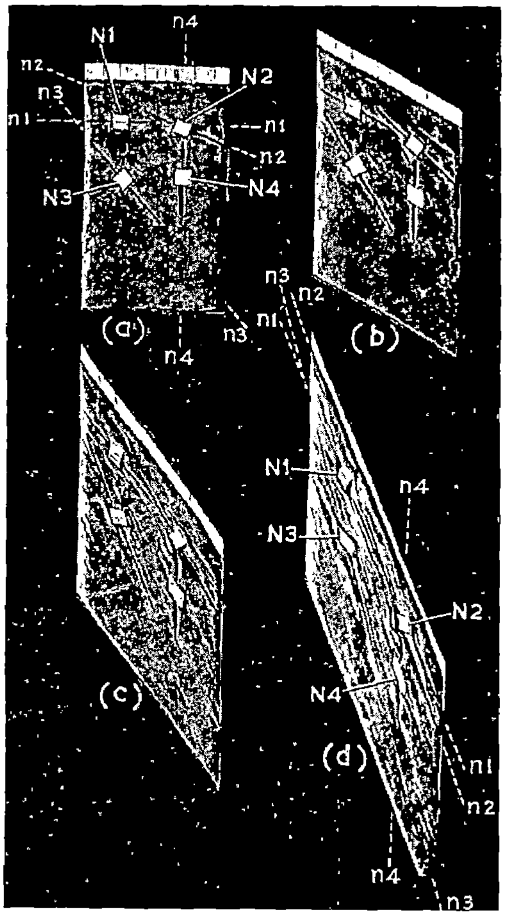

Fig. 4. Four identical anisotropic segregates deform differently according to their initial orientations in rheid matrix deformed by laminar flow

is established by the reversal in sense of the superimposed shear.

Fig. 3 illustrates the case where both the segregate axes and the superimposed shear are perpendicular to the aggregate axes. In Fig. 3*a*, the aggregate axes, *G*1–*G*5 and *G*6–*G*10, which may be equated to stratal bedding, are the locus of rigid segregates respectively of low and high aspect ratio, while *H*6–*H*10 and *H*1–*H*5 represent the corresponding sets of rheid segregates. Fig. 3*b* shows the effect of superimposing an anticlinal fold by axial plane shear. The segregates of high aspect ratio, *H*1–*H*5 and *G*6–*G*10, resist rotation and remain in the axial (shear) plane. Of those of lower aspect ratio, the *G*1–*G*5 segregates assume orientations corresponding to slaty[10] cleavage divergent toward the anticlinal crest, while the *H*6–*H*10 segregates assume orientations convergent toward the anticlinal crest after the manner of fracture[10] cleavage. This model suggests an analogy to the attitude of fold cleavage where it is determined by the orientation of mineral segregates, varying with the strata, which have originated as mimetic growths in early axial plane cleavage, and thereafter responded unequally and differentially to continuing deformation. In this context, three accepted types of cleavage orientation may be causally united under the one shear fold system.

Fig. 4 illustrates the different behaviour of four similar *N*-segregates according to their initial orientation with respect to the superimposed shear. The axes *n*1, *n*2, etc., are specified as the respective aggregate axes of the individual segregates, corresponding to their internal laminal direction before deformation. When right lateral shear is imposed, the subsequent internal deformation of the segregates is alternatively by right-hand or left-hand slip, or, as in *N*2, by both, successively, according to the stage of movement. In the advanced stage of this type of shear deformation, as in Fig. 4*d*, all formal elongations and all aggregate axes except those in the shear plane (for example, *n*4) tend to become parallel to the gross strain elongation.

Fig. 5 illustrates how the one uniform shear may appear to produce contrary rotations in similar *G*-segregates according to the initial angle of shear with the bedding planes (aggregate axes). Thus, *G*3 and *G*4 (Fig. 5*a*) rotate anticlockwise with respect to their aggregate axis (Fig. 5*b*), whereas *G*7 and *G*8 do the opposite. Of particular interest is the 'rigid area' divided in two parts (*G*9 and *G*10) by a line of scission perpendicular to the superimposed shear direction. It may be seen in Figs. 5*a* and *b* that although the 'basement' shearing is in a left lateral sense, not only do the rigid areas, *G*9 and *G*10, move in a right lateral sense with respect to one another, but the 'fault' separating them also rotates relatively in the same sense. In this context, the 'sense of rotation' is a relative matter depending on the interaction of rigid and rheid qualities which vary according to initial orientations as well as to the stage of deformation.

It is of interest to consider a composite segregate that consists of a rigid nucleus with a rheid periphery (as if *G*1 were inside *H*1 in Fig. 2), or one that grows by progressive syntectonic accretion, especially if the accretion is polarized along the infinitesimal strain axis. With appropriate orientation, a superimposed clockwise shear can cause such a segregate to assume a formal '*S*-structure' even though the shear rotates both the segregate and its environment in a clockwise sense with respect to a fixed direction. This is of importance when recalling that an *S*-structure in a mineral segregate is accepted as indicating anticlockwise rotation[11]. On a global scale it is also of interest to extend the implications of Fig. 5 to the conclusion that sub-crustal rheid flow in a given direction may induce fault movements in crustal blocks that may appear to contradict it in both direction and rotational sense.

The role of model presentations must be kept in proper perspective and their limitations appreciated. As Suppes[12] claims, a model drastically simplifies the true physical phenomena and describes only certain aspects of them. In this way, the idealized extremes shown in rheoplex models may be regarded as qualitative components effective in varying degrees in an ultimate deformation which is variously a compromise between rigidity and rheidity. The separate representation of these properties is intended to help the elucidation of what Simpson[13]

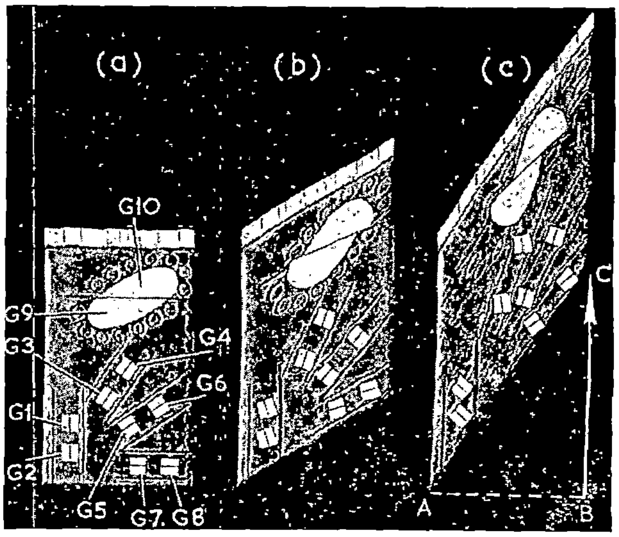

Fig. 5. Left lateral shear of rheid matrix induces contrary rotational effects in various rigid bodies disposed within it

distinguishes as "immanent" qualities, that characterize particular relationships, from "configurational" qualities, that are related to particular materials.

RECOMBINATION OF CHLORINE ATOMS

By E. HUTTON

Rocket Propulsion Establishment, Westcott, Bucks

THE recombination of chlorine atoms has been the subject of two recent communications[1,2], Linnett and Booth[1] having obtained a value for the overall termolecular rate constant which is approximately two orders of magnitude less than that reported by Bader and Ogryzlo[2].

Both authors used the isothermal calorimetric technique[3] to measure the decay of the atom concentration. This method is known to give results of dubious reliability in the presence of excited species, and it is sometimes found that only a fraction of the energy of the atom recombination is accommodated on the catalytic wire[4]. We have used an alternative technique to monitor the atom concentration, and have therefore measured our rate constants by an independent method.

The atoms were produced in a flow system by a radio-frequency discharge through pure chlorine gas. The reaction cell was of 2·9 cm internal diameter and the walls were 'poisoned' with sulphuric acid[5].

Downstream from the point of injection of the chlorine atoms a multiperforated jet permitted the addition of nitrosyl chloride gas, which was used to estimate the absolute value of the atom concentrations by means of the fast reaction:

$$\mathrm{Cl} + \mathrm{NOCl} \rightarrow \mathrm{Cl_2} + \mathrm{NO}$$

Chlorine was obtained from Imperial Chemical Industries, Ltd., and quoted as 99·99 per cent pure. The nitrosyl chloride was prepared by the reaction of nitric oxide with molecular chlorine and was purified by fractional vaporization. Pressures were measured on a McLeod gauge filled with sulphuric acid, which was standardized against a conventional mercury McLeod gauge.

For each experiment the absolute value of the chlorine atom concentration was determined at one position in the reaction tube by titration with nitrosyl chloride, and the relative concentrations of the atoms along the remainder of the tube were obtained by measurement of the intensity (I) of the red glow emitted from the recombining gas.

The dependence of I on the chlorine atom concentration was determined[6], and hence absolute values for its concentration obtained at several positions along the tube.

If the recombination mechanism is expressed[1,2]:

$$\mathrm{Cl} + \mathrm{Cl} + \mathrm{Cl_2} \xrightarrow{k_{\mathrm{Cl}_2}} \mathrm{Cl_2} + \mathrm{Cl_2}$$

$$\mathrm{Cl} + \mathrm{wall} \xrightarrow{k_w} \tfrac{1}{2}\,\mathrm{Cl_2}$$

then

$$\frac{-\mathrm{d[Cl]}}{\mathrm{d}t} = 2\,k_{\mathrm{Cl}_2}\,[\mathrm{Cl}]^2\,[\mathrm{Cl_2}] + k_w\,[\mathrm{Cl}] \qquad (1)$$

From low-pressure experiments at low chlorine atom concentration a value for k_w of 0·70 sec^{-1} was obtained corresponding to a wall recombination efficiency (γ) = $3{\cdot}5 \times 10^{-5}$, which is in good agreement with previous work[2].

k_{Cl_2} was determined over a range of pressure and chlorine atom concentrations (Fig. 1); our results are approximately half those obtained by Bader and Ogryzlo, and k_{Cl_2} decreases with increase in chlorine atom concentration. Bader and Ogryzlo's results, which are plotted for comparison on the same graph, show the same general trend.

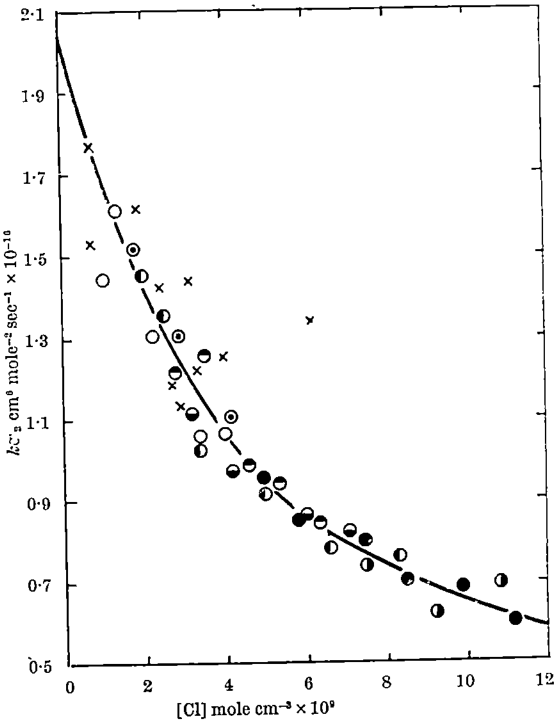

Fig. 1. Experimental values of k_{Cl_2} at the pressures (torr): ⊙, 2·03; ○, 1·65; ◐, 1·21; ⊖, 0·91; ⊖, 0·66; ◑, 0·58; ●, 0·33; ×, values obtained by Bader and Ogryzlo (divided by 2 for comparison)

Such a decrease is not in accordance with equation (1), which must therefore represent an over-simplified presentation of the reaction.

A more detailed mechanism for the removal of the chlorine atoms is:

$$\mathrm{Cl} + \mathrm{Cl_2} \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} \mathrm{Cl_3}$$

$$\mathrm{Cl_3} + \mathrm{Cl} \xrightarrow{k_2} \mathrm{Cl_2} + \mathrm{Cl_2}$$

$$\mathrm{Cl} + \mathrm{wall} \xrightarrow{k_w} \tfrac{1}{2}\,\mathrm{Cl_2}$$

Hence:

$$\frac{-\mathrm{d[Cl]}}{\mathrm{d}t} = \frac{2\,k_1\,k_2[\mathrm{Cl}]^2\,[\mathrm{Cl_2}]}{k_{-1} + k_2[\mathrm{Cl}]} + k_w[\mathrm{Cl}] \qquad (2)$$

From equations (1) and (2) the measured overall termolecular rate constant (k_{Cl_2}) is given by:

$$k_{\mathrm{Cl}_2} = \frac{k_1\,k_2}{k_{-1} + k_2\,[\mathrm{Cl}]}$$

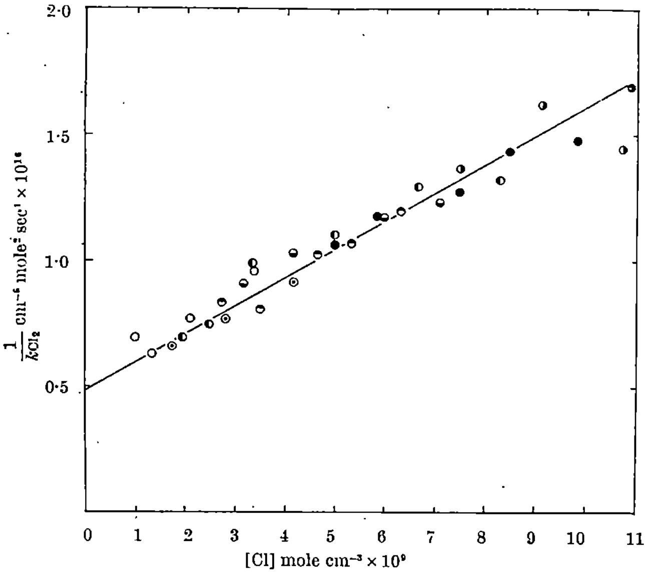

Fig. 2. Dependence of the reciprocal of the termolecular rate 'constant' on the atomic chlorine concentration

or:

$$\frac{1}{k_{Cl_2}} = \frac{[Cl]}{k_1} + \frac{k_{-1}}{k_1 k_2}$$

At very low concentrations where $k_{-1} \gg k_2$ [Cl], then $(k_{Cl_2})_{[Cl]\to 0} = \frac{k_1 k_2}{k_{-1}}$. $\frac{1}{k_{Cl_2}}$ is plotted against [Cl] in Fig. 2. The slope of the line gives $\frac{1}{k_1}$ and from the intercept we obtain $\frac{k_{-1}}{k_1 k_2}$.

From Fig. 2:

$$k_1 = 9{\cdot}09 \times 10^7 \text{ cm}^3 \text{ mole}^{-1} \text{ sec}^{-1}$$

and

$$\frac{k_1 k_2}{k_{-1}} = 2{\cdot}04 \times 10^{16} \text{ cm}^6 \text{ mole}^{-2} \text{ sec}^{-1}$$

hence

$$\frac{k_2}{k_{-1}} = 2{\cdot}24 \times 10^8 \text{ cm}^3 \text{ mole}^{-1}$$

If we assume that the reaction of Cl and Cl_3 takes place with unit collisional efficiency, then we obtain an upper limit for k_2 of $1{\cdot}7 \times 10^{14}$ cm^3 mole^{-1} sec^{-1} and, by substitution, $k_{-1} \leqslant 7{\cdot}6 \times 10^5$ sec^{-1}.

At low atom concentrations:

$$\frac{[Cl_3]}{[Cl]} = \frac{k_1 [Cl_2]}{k_{-1}}$$

and at a pressure of 2 torr:

$$[Cl_3] \geqslant 1{\cdot}2 \times 10^{-5} [Cl]$$

The value of the termolecular rate constant obtained for chlorine atom recombination at very low atom concentrations ($2{\cdot}04 \times 10^{16}$ cm^6 mole^{-2} sec^{-1}) is in fairly good agreement with the value of 4×10^{16} cm^6 mole^{-2} sec^{-1} obtained by extrapolating Bader and Ogryzlo's data from experiments carried out in pure chlorine, and is in good agreement with their data from indirect determinations in the presence of inert gases.

A full account of this work is to be published in detail elsewhere. I thank Mr. H. Williams for helpful discussion and criticism.

QUANTITATIVE DETERMINATION OF PROGESTERONE IN HUMAN PLASMA BY THIN-LAYER AND GAS-LIQUID RADIOCHROMATOGRAPHY

By WILLIAM P. COLLINS and DR. IAN F. SOMMERVILLE
Endocrine Laboratory Unit, Chelsea Hospital for Women and Institute of Obstetrics and Gynæcology, University of London

IN 1954, progesterone was isolated from human peripheral venous blood and the concentration determined in samples collected during late pregnancy[1]. Later, although several methods were developed for the determination of the hormone in plasma samples of reasonable volume[2-4], it was apparent that a considerable increase in sensitivity would be required for the determination of plasma concentrations in early pregnancy and the menstrual cycle. For this purpose and to achieve a higher degree of specificity, the method developed in this department[2,4] which involved alumina chromatography and the formation of the isonicotinic acid hydrazone, was modified by the introduction of preliminary purification on silica gel, followed by paper chromatography and the formation of the thiosemicarbazone. There was a ten-fold increase in sensitivity and, using an internal standard of progesterone-4-^{14}C, the method was suitable for the assay of 10-ml. samples collected during the luteal phase of the menstrual cycle[5]. Further information on the plasma concentration of the hormone during the cycle has been obtained by a double isotope dilution technique[6] and the application of a fluorimetric method has been reported[7]. However, the former technique is time-consuming and expensive, while the latter is liable to interference by non-specific material.

In general, physicochemical methods for the determination of steroids in blood are inconveniently laborious—specificity being achieved by the use of several chromatographic steps and re-chromatography of a derivative. The time involved in the analysis may be from 3 to 14 days. The introduction of gas-liquid chromatography for steroid analysis offered the hope of a more rapid and, at the same time, highly sensitive and specific method. There were, however, two main problems—to effect adequate preliminary separation without resort to laborious techniques and to ensure that the method is quantitative. The present report describes the manner in which the former has been resolved by the use of two-dimensional thin-layer chromatography; the latter by the simultaneous determination of an isotopically labelled internal standard in terms of integrated radioactivity. The new method has a high degree of specificity and the sensitivity is adequate for the determination of the hormone in 5-ml. samples of pregnancy plasma and 10-ml. samples collected during the menstrual cycle. The time involved is three hours plus the duration of the gas-liquid radiochromatography (40–80 min depending on choice of temperature and stationary phase).

While this work was in progress there were preliminary reports on the application of gas-liquid chromato-

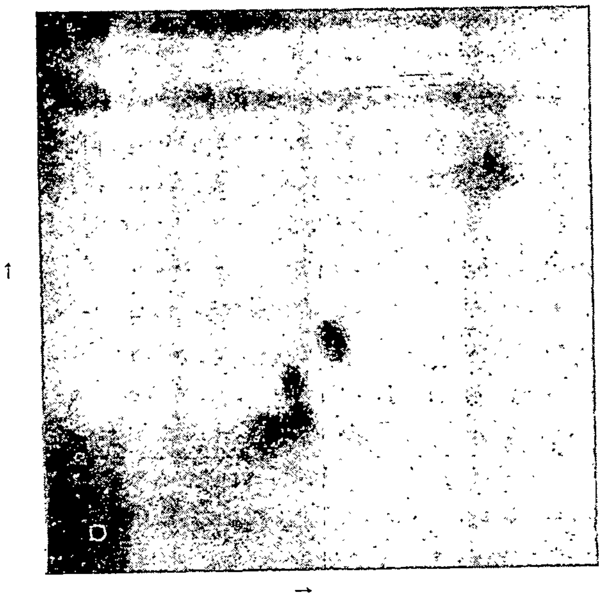

Fig. 1. Two-dimensional thin-layer chromatogram showing 20α-hydroxy-pregn-4-en-3-one (left); Δ4-androstene-3,20-dione (right); 20β-hydroxy-pregn-4-en-3-one (above); progesterone (right)

graphy to the determination of progesterone in extracts of human myometrium[8] and to the identification of the hormone in human pregnancy plasma[9].

All solvents are purified by standard techniques and redistilled prior to use. The stationary phase for thin-layer chromatography is 'Kieselgel' with calcium sulphate binder and fluorescent indicator from Camag, Ltd. (obtained from Griffin and George Ltd., London). Gas-liquid radiochromatography is performed on a Pye panchromatograph with a macro-argon ionization detector; the radioactivity being measured simultaneously by a gas proportional counter coupled to an Ekco ratemeter (type *N701A*) which incorporates an integration unit. The instrument was modified so that all the effluent gas from the column passes through the argon detector before combustion. The columns are 5′ in length, and for the routine method the stationary phase is 1 per cent *cyclo*hexane-dimethanol succinate (CDMS) on 'Gas Chrom. *P*.' 60–80 mesh (W. G. Pye and Co. Ltd., Cambridge). Progesterone-4-^{14}C (21·7 mc./mM) was obtained from the Radiochemical Centre, Amersham, Bucks.

Peripheral venous blood is withdrawn by a non-greased syringe, transferred to a centrifuge tube containing heparin B.P. (10 units/ml. blood), centrifuged and the plasma removed. An internal standard of 0·25 μg progesterone-4-^{14}C is added to each sample. After the addition of an equal volume of N/3 sodium hydroxide, the mixture is shaken for 5 min; extracted with 2 × 100 ml. ether; the extract washed with 20 ml. distilled water and evaporated to dryness *in vacuo*. The extract is then transferred with 3 × 5 ml. methanol/chloroform (1 : 1) to a small conical test tube and evaporated to dryness under nitrogen at 60° C (a small volume of the same mixture is added to wash the extract into the tip of the tube and after re-evaporation the tube may be stored in a desiccator).

Glass plates 20 cm × 20 cm are coated with 'Kieselgel' and stored in a desiccator prior to use. The extracts are applied to separate plates (using a glass capillary and 3 × 0·05 ml. methanol : chloroform, 1 : 1) on a spot 2 cm in from either side of the right-hand corner. The first system used is benzene/ethyl acetate (3 : 2), the solvent front being allowed to travel 15 cm. The plates are then removed, thoroughly dried, turned through 90°, and re-run in ether/dimethylformamide (99 : 1), the solvent front again advancing 15 cm. The plates are then removed and dried. The compounds are located under ultra-violet light (2537 Å) and demarcated with a fine needle. As an additional safeguard, the position of the steroid may be located by extrapolation from two standards applied to the contralateral corners of the plate at the beginning of each chromatogram. The silica gel containing the compound is loosened with a microspatula; aspirated on to a filter disk (1 cm diam., No. 3 grade); eluted with 3 × 0·5 ml. ethanol under positive pressure and the eluate evaporated under nitrogen at 60° C. (The elution apparatus was devised in the department by Dr. M. I. Stern.) Fig. 1 is a photograph of the ultra-violet absorption of four authentic steroid standards, and Fig. 2 shows the result obtained in an extract of pregnancy plasma. In some instances, examination of the plate in ultra-violet light reveals other compounds which are under investigation.

Where gas-liquid chromatography is not available, the progesterone in the eluate can be determined by formation of the thiosemicarbazone and the recovery of the internal standard obtained by liquid scintillation counting.

For gas-liquid radiochromatography, the eluate is transferred with 3 × 20 μl. methanol/chloroform (1 : 1) to the centre of a rectangle of folded stainless-steel gauze (previously flamed and held in a clamp over a warm surface) which is dropped on to the top of a 1 per cent CDMS column after cessation of the gas-flow. All conditions are carefully standardized and the chromatography carried out at 210° C. The retention time of progesterone at this temperature is 72 min and the relative retention time of other steroids can be expressed in terms of cholestane or using progesterone itself as the marker. For routine work it is permissible to shorten the retention time of progesterone by using a higher temperature. The amount of progesterone on the differential trace from the argon detector is calculated from the peak area (mm^2) and reference to a calibration curve. From this, the amount of internal standard recovered (calculated from integrator units on the radiochromatography recorder) is subtracted and the results corrected for loss. Table 1 shows the relationship between μg progesterone, peak height, area and integrator units at one of the concentrations used for the calibration. Peak height is not satisfactory at relevant concentrations whereas satisfactory calibration curves are obtained from peak area and integrator units. The sensitivity of the argon detector

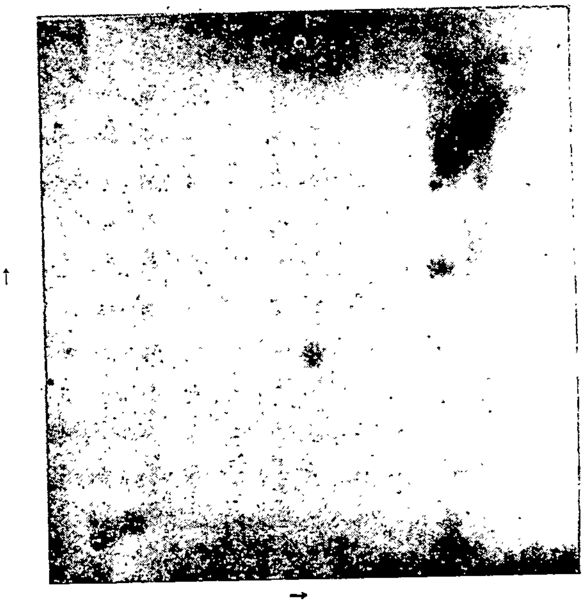

Fig. 2. Two-dimensional thin-layer chromatogram showing progesterone (centre of plate) from extract of 8 ml. pregnancy plasma (spot includes internal standard)

is tested daily by calculating the peak area (and recovery) of a sample of pure progesterone-4-^{14}C. In this connexion, it was found that a small proportion (2·5 per cent) of the standard consists of an isotopically labelled component (possibly the 17α-epimer) which appears immediately before the main peak.

* Full-scale deflexion.

For the determination of progesterone during the luteal phase of the menstrual cycle and pregnancy, adequate sensitivity is obtained on the panchromatograph with a current range of 10^{-9} amp; the ratemeter at minimum sensitivity (full-scale deflexion 1,000 p.p.s. × 1/3 recorder sensitivity) and a chart speed of 5″/h. This permits determination of 0·01 μg. However, as shown in Table 1, higher sensitivity can be obtained by decreasing the attenuation or amplifying the signal from the argon detector through a second integrator and by increasing the chart speed.

Figs. 3 and 4 are photographs of differential traces at 10^{-9} amp. It will be seen that there is adequate separation of a variety of steroids which in the thin-layer system have R_F values close to that of progesterone. Δ4-Androstenedione is not shown in Fig. 3, but it has a retention time between that of 5β-pregnane-3,20-dione and Δ^5-pregnen-3β-ol-20-one. At this sensitivity progesterone is the only steroid present in the eluate from plasma collected during the luteal phase of the cycle or pregnancy. It will be noted that the minimum of non-steroid material is applied to the column and this obviates contamination of the detector.

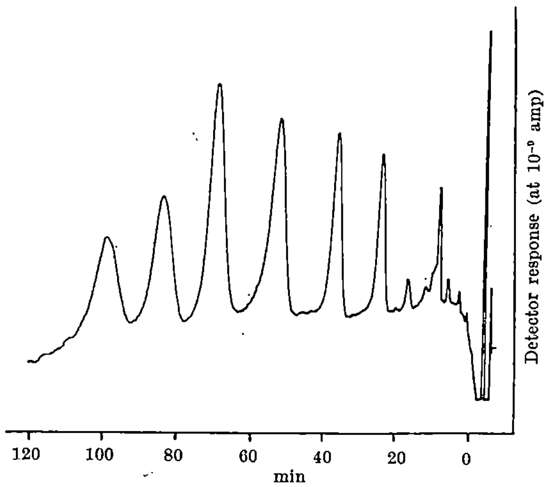

Fig. 3. Differential trace from macro-argon detector (1 per cent CDMS; 210° C, 10^{-9} amp; 1,000 V; chart speed 5″/h). Peaks represent from right to left: solvent; 5β-androstane-3,20-dione; 5β-pregnane-3,20-dione; Δ^5-pregnen-3β-ol-20-one; progesterone, 20β-hydroxy-pregn-4-en-3-one; 20α-hydroxy-pregn-4-en-3-one

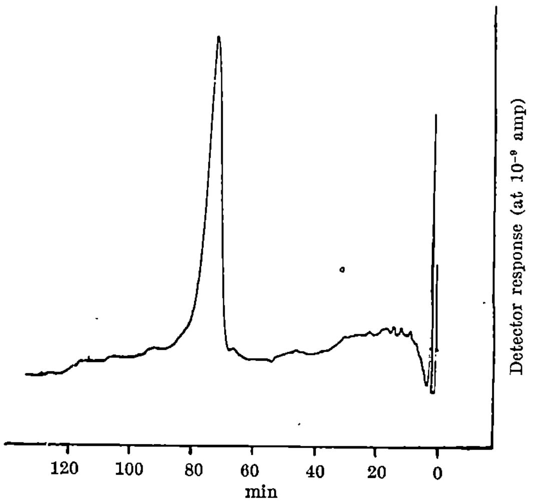

Fig. 4. Same conditions as Fig. 3: progesterone (endogenous plus internal standard) eluted from plate shown in Fig. 2

Table 2 shows examples of the application of the method and includes replicate determinations and the recoveries of the internal standards. The latter are usually higher than 80 per cent, and the loss appears to be mainly due to the technique of transferring the eluate to the metal gauze (since a similar loss occurs in a proportion of standards).

Table 2. Male Plasma

Subject No.	Age (yr)	Internal standard (μg)	Recovery (%)	Progesterone (μg/100 ml.)
1	28	—	—	0·20
2	30	—	—	0·27
3	55	0·5	75·6	0·30
3	55	0·5	81·5	0·29

Female Plasma

(*a*) Early pregnancy (replicates on pool)

Recovery of internal standard (%)	Progesterone μg/5 ml. aliquot
84	0·22
100	0·21
20	0·22
85	0·19

(*b*) Menstrual cycle

Subject No.	Age (yr)	Day of cycle	Duration (days)	Recovery of internal standard (%)	Progesterone (μg/100 ml.)
1	28	4	32	24	0·52
2	23	9	29	95	0·75
3	24	10	30	76	0·97
4	18	13	32	96	0·9
5	17	17	29	12	3·9
6	34	19	28	101	1·4
7	35	19	28	90	2·3
8	38	21	27	99	0·6
8	38	23	27	100	0·53
4	18	24	30	100	1·1
3	24	26	30	94	1·1
9	25	28	35	80	1·1

Very occasionally (for example, three of the recoveries in Table 2), major loss has occurred due to a faulty seal between the base of the column and the molecular entrainer. The analysis may be repeated or the result corrected in terms of the recovery of internal standard. The validity of the correction is indicated by the results of the replicate determinations on pooled pregnancy plasma.

Finally, with regard to specificity, this is achieved by the two-dimensional thin-layer chromatography and by the 1 per cent 'CDMS' column. The simultaneous recording of radioactivity confirms the identity of the progesterone peak at each analysis. If other Δ^4-3-ketones are detected on the thin-layer plate, these can be eluted separately or as a group and then subjected to gas-liquid chromatography. Further evidence on specificity has been obtained by the use of other stationary phases—1 per cent neopentyl glycol adipate (NPGA) and the silicone polymers, 3 per cent '*QF*-1' and 3 per cent '*SE*-30'. In addition, the 1 : 1 dimethylhydrazone and the *bis*ethylene ketal derivatives of endogenous progesterone have been chromatographed on 1 per cent CDMS and 3 per cent '*QF*-1'.

ENZYMATIC CONVERSION OF ALL-*cis*-POLYUNSATURATED FATTY ACIDS INTO PROSTAGLANDINS

By D. A. VAN DORP, R. K. BEERTHUIS, D. H. NUGTEREN and H. VONKEMAN

Unilever Research Laboratory, Vlaardingen, Holland

IN view of the results obtained by our group[1] and by S. Bergström *et al.*[2] the relationship between essential fatty acids and prostaglandin seems now established. In both laboratories arachidonic acid could be converted into prostaglandin E_2 (PGE_2) in high yield.

It has further been predicted[1,2] that 'homo-γ-linolenic acid' (all-*cis*-eicosa-8,11,14-trienoic acid) will act as precursor for PGE_1, which has now been proved. Moreover, we were interested to find out whether the enzyme system could also convert other polyunsaturated acids of related structures. This appeared to be the case.

All-*cis*-[1-^{14}C]-eicosa-8,11,14-trienoic acid was obtained by carboxylation of the Grignard derivative of all *cis*-1-bromo-7,10,13-nonadecatriene with $^{14}CO_2$. The product was purified as methyl ester by column and thin-layer chromatography over silver nitrate[3,4] and saponified; the specific activity of the acid was 32 × 10^6 d.p.m./mg, the purity 98 per cent as checked by gas–liquid chromatography, and the *trans* content less than 1 per cent as determined by infra-red spectroscopy.

The vesicular glands of sheep were collected immediately on slaughter and stored up to 2 months on dry ice. After thawing, the glands were stripped of connective tissue and cut finely. This material was homogenized with a turmix in an equal volume of ice-cold 0·15 M phosphate buffer (*p*H 7·5).

1 mg [1-^{14}C]-eicosa-8,11,14-trienoic acid dissolved in 0·1 ml. 96 per cent ethanol was added to a homogenate obtained from 25 g glands, and the mixture incubated aerobically at 37° for 30 min. The incubation was terminated by addition of 160 ml. 96 per cent ethanol containing 2·4 ml. 1 N hydrochloric acid, and the prostaglandins were concentrated according to Samuelsson[5]. As control we used an equal amount of homogenate with the same radioactive substrate to which at the start 160 ml. of the acidified 96 per cent ethanol had been added.

From both concentrates 0·1 part was subjected to thin-layer chromatography on 'Silicagel *G*', using solvent system '*A* I' according to Greén and Samuelsson[6], the reference being PGE_1. The area with R_F equal to PGE_1 was scraped off, and the rest of the spots stained with iodine. In this way it could be checked whether the removal of PGE from the plate was complete; degradation of the PGE by iodine was avoided as much as possible, and other spots were made visible. The various spots were eluted from the 'Silicagel' with methanol, the methanol evaporated and the radioactivity measured in a Packard 'Tricarb' liquid scintillation spectrometer.

As seen in Fig. 1, the bulk of the radioactivity was present in the spot with the same mobility as the reference sample of PGE_1 (R_F 0·60), whereas the control did not show a peak of radioactivity in this region. In several incubation experiments we have observed the appearance of a peak *X* between the PGEs and the solvent front. The nature of peak *X* is not yet clear, but the fact that a similar peak did not appear in the controls indicates that it is also formed from the unsaturated fatty acid by an enzymatic reaction. Unconverted substrate remained for the greater part in the light petroleum used during the concentration procedure.

Thin-layer chromatography was repeated with another 0·1 part of the concentrate and the fraction with R_F 0·60 isolated and re-chromatographed on a thin-layer of 'Silicagel *G*' impregnated with 10 per cent silver nitrate using solvent system '*A* II'[6]. After development the zones were scraped off, eluted from the silica-gel[6], and the radioactivity measured. It was found for the greater part at R_F 0·86, which was equal to that of PGE_1 (R_F PGE_2 0·71) (Fig. 2).

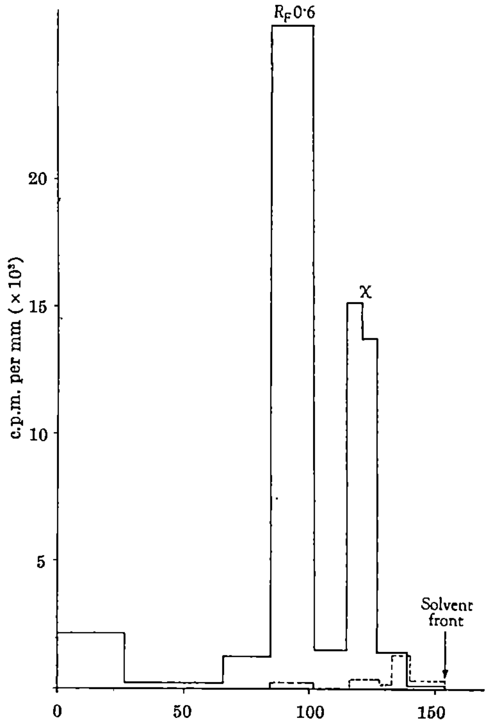

Fig. 1. Distribution of radioactivity (thin-layer chromatography on 'Silicagel *G*') of PG*E* concentrate obtained after incubation of [1-^{14}C]-homo-γ-linolenic acid with homogenate of vesicular glands of sheep (——); (- - - -) is the control

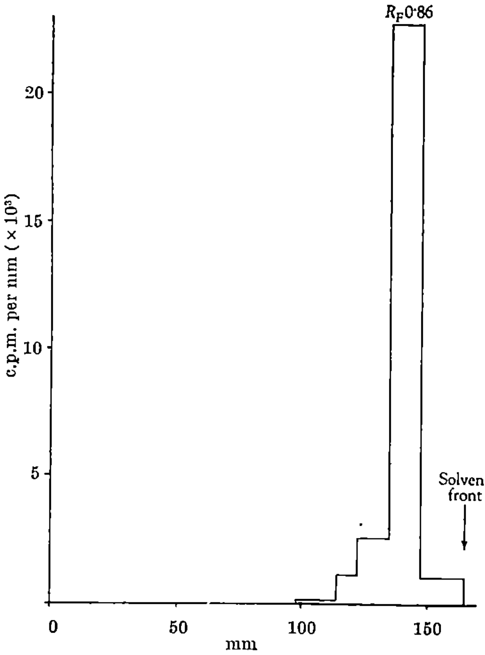

Fig. 2. Distribution of radioactivity (thin-layer chromatography on 'Silicagel *G*'/AgNO₃) of the PG*E* spot isolated on 'Silicagel *G*' (Fig. 1)

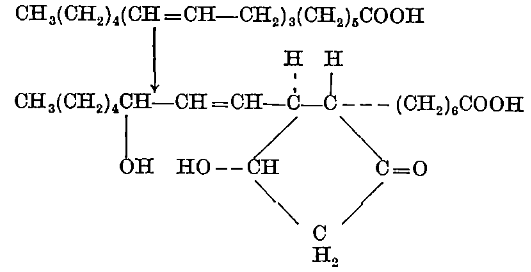
Based on the radioactivity found in the PGE_1 thus formed, it is concluded that homo-γ-linolenic acid was converted into PGE_1 to the extent of at least 18 per cent:



Conversions of straight-chain fatty acids with 18 and 19 carbon atoms containing 3 and 4 skipped double bonds* have also been investigated. A homogenate of the vesicular glands of sheep was made in the same way as described here and diluted with three times its volume of phosphate buffer. By centrifuging during 10 min at 4,000*g* the connective tissue was removed from the homogenate. The turbid and light-brown supernatant contained 5–10 mg protein and 2–5 μg PG*E*/ml. and was suitable as such for examining the conversion of non-labelled fatty acids into prostaglandins. To this end, 0·1 mg of a fatty acid in 2 ml. *tris* buffer (*p*H 9) was incubated with an amount of supernatant containing 10 mg protein. The PG*E* content after the incubations could be determined directly in the crude ethereal extract of the acidified incubation mixture by addition of methanolic potassium hydroxide (final concentration 0·5 N) followed by measuring the increase of the extinction at 280 mμ[7]. In this way we could demonstrate the conversion of all-*cis*-eicosa-8,11,14-trienoic acid ($\Delta^{8,11,14}$ $C_{20:3}$) (purity 92 per cent), all-*cis*-nonadeca-7,10,13-trienoic acid ($\Delta^{7,10,13}$ $C_{19:3}$) (purity > 98 per cent), all-*cis*-eicosa-5,8,11,14-tetraenoic acid ($\Delta^{5,8,11,14}$ $C_{20:4}$) (purity > 98 per cent) and all-*cis* - nonadeca - 4,7,10,13 - tetraenoic acid ($\Delta^{4,7,10,13}$ $C_{19:4}$) (purity 95 per cent) into prostaglandins and probably *nor*-prostaglandins.

The corresponding fatty acids with eighteen carbon atoms, all-*cis*-octadeca-6,9,12-trienoic acid (purity > 99 per cent) and all-*cis*-octadeca-3,6,9,12-tetraenoic acid (purity 92 per cent) appeared to be scarcely or not at all converted into prostaglandin-like substances.

Additional proof for the conversion of $\Delta^{4,7,10,13}$ $C_{19:4}$ into '*nor*-prostaglandin E_2' was obtained as follows:

Methyl nonadeca-4,7,10,13-tetraynoate was reduced with tritiated hydrogen gas* over Lindlar's catalyst. The crude methyl ester was purified by thin-layer chromatography on 'Silicagel *G*' impregnated with silver nitrate and afterwards saponified. The specific activity of [³H]-$\Delta^{4,7,10,13}$ $C_{19:4}$ thus obtained was 2×10^9 d.p.m./mg. This acid (0·1 mg) was incubated with a homogenate of 7·5 g vesicular glands of sheep in an equal volume of 0·15 M phosphate buffer (*p*H 7·5) during 30 min at 37°, and the incubation mixture worked up in the usual way. The prostaglandins were isolated from the concentrate by thin-layer chromatography on 'Silicagel *G*' (see aforementioned). To 0·3 part of this purified material non-radioactive PGE_1 (46 μg) and PGE_2 (39 μg) were added. The mixture was afterwards subjected to thin-layer chromatography on 'Silicagel *G*' impregnated with 10 per cent silver nitrate, and the various zones were scraped from the plate and eluted. The radioactivity of each fraction was measured as well as the increase of ultraviolet absorption at 280 mμ after treatment with alkali. Fig. 3 shows that the radioactive prostaglandin formed coincides with PGE_2, from which we conclude that the enzyme system had converted $\Delta^{4,7,10,13}$ $C_{19:4}$ into *nor*-PGE_2.

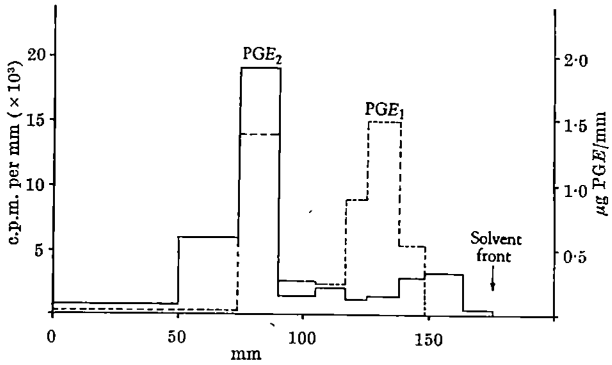


Fig. 3. Distribution of radioactivity (——) (thin-layer chromatography on 'Silicagel *G*'/AgNO₃) and of PG*E* (– – – –) after incubation of [³H]-$\Delta^{4,7,10,13}$ $C_{19:4}$ with a homogenate of vesicular glands of sheep and after addition of PGE_1 and PGE_2

In other experiments 30 mg $\Delta^{8,11,14}$ $C_{20:3}$ and 30 mg $\Delta^{7,10,13}$ $C_{19:3}$ were each dissolved in 60 ml. 0·2 M *tris* buffer (*p*H 9) and incubated with 240 ml. (2·4 g protein) of the aforementioned 4,000*g* supernatant during 2 h at 37°. The reaction mixtures were acidified and extracted with diethyl ether. Based on the molar extinction of 26,800 for PG*E* 278 (ref. 7) the ethereal extract contained 11·4 mg prostaglandin in the experiment with $C_{20:3}$ and 12·1 mg '*nor*-prostaglandin' with $C_{19:3}$. The control (incubation without added substrate) contained only 1·0 mg PG*E*. These experiments indicate that by incubation with a suitable fatty acid the amounts of prostaglandin present in the homogenate can be increased at least by a factor 10.

Part of the PGE_1 and the *nor*-PGE_1, obtained in the experiment described here, was purified by thin-layer chromatography on 'Silicagel *G*' and 'Silicagel *G*' impregnated with silver nitrate successively. The pure PGE_1 thus obtained was tested on guinea pig ileum against a pure preparation of PGE_2 prepared from vesicular glands of sheep. Its activity was about half that of PGE_2. The purified *nor*-PGE_1, containing maximum

---

* Of these acids all-*cis*-nonadeca-4,7,10,13-tetraenoic acid and all-*cis*-octadeca-3,6,9,12-tetraenoic acid have not yet been described in the literature. Their preparation will be the subject of a publication by H. J. J. Pabon, D. van der Steen and D. A. van Dorp.

* The reduction was carried out by Mr. J. Parmentier, Central Laboratories T.N.O., Delft, Holland.

5 per cent PGE_1, had scarcely any activity at all when compared with the same standard. It is interesting to note that all-*cis*-nonadeca-7,10,13-trienoic acid scarcely showed any essential fatty acid activity[8]. *Nor*-PGE_2 obtained from an incubation experiment with $\Delta^{4,7,10,13}$ $C_{19:4}$ was purified by the same techniques. After purification the sample still contained about 25 per cent PGE_2 derived from the original homogenate. Owing to this relatively high amount of natural PGE_2 we cannot yet give values for the biological activity of *nor*-PGE_2.

So far as the properties of the enzyme system are concerned, our first impressions can be summarized as follows: By centrifuging the 4,000*g* supernatant during 1 h at 100,000*g* 20 per cent of the protein was precipitated. This protein was able to convert the polyunsaturated fatty acids into prostaglandins while only little activity was shown by the remaining clear supernatant. It should be noted that a supernatant obtained by centrifuging a homogenate in 0·25 M sucrose at 20,000*g* during 1 h was found to be fully active[1].

When the incubations are carried out anaerobically, only small amounts of prostaglandins are formed, so oxygen is essential. Usually the incubations were carried out at *p*H 9, where the yield of PGE is at its maximum.

These investigations have once more shown the relation between essential fatty acids and prostaglandins.

We thank Prof. S. Bergström, of the Karolinska Institutet, Stockholm, for a sample of prostaglandin E_1 and E_2, and Dr. J. de Boer, of our laboratory, for testing the various samples for biological activity.

PHYTOHÆMAGGLUTININ-INDUCED CYTOTOXIC ACTION OF NORMAL LYMPHOID CELLS ON CELLS IN TISSUE CULTURE

By Dr. GÖRAN HOLM*, Dr. PETER PERLMANN* and Dr. BENGT WERNER†

Wenner-Gren Institute for Experimental Biology, University of Stockholm, and Departments of Medicine and Surgery, Seraphimer Hospital, Stockholm

THERE is some evidence that immunological cell injury can be mediated by lymphoid cells, most probably lymphocytes. When antigen-carrying 'target' cells, usually grown in monolayer culture, are exposed to lymphoid cells from spleen, lymph nodes, thoracic duct or peripheral blood of sensitized animals, an appreciable proportion of the target cells will be lysed within 24–36 h. This cell injury is immunologically specific and no complement needs to be added. Lymphocyte-induced cell damage has been found in autoimmune[1–4], isoimmune and heteroimmune systems[5–9]. It occurs under conditions where sera from the sensitized animals were found to have no effect[1,2,4,6,8]. Homologous lymphoid cells from non-sensitized animals seem to be inactive. However, a certain potentiating effect of serum from sensitized animals has been observed in some cases[1,5,10].

The mechanism of this lymphocyte activity is unknown. One of the main features observed in this reaction is the early aggregation of the lymphocytes round the target cells. This can be seen already 1–3 h after the beginning of the incubation, before any noticeable cell damage appears under the microscope[1]. This step, which obviously is immunologically specific, seems to be important for establishing a necessary close contact between lymphocytes and target cells. The second step, the tissue cell damage, may then represent either a specific or a non-specific activity of the lymphocytes (cf. ref. 10).

In order to examine the significance of lymphocyte-target cell aggregation for the initiation of cell damage, it seemed desirable to induce this phenomenon with lymphoid cells from non-sensitized animals. Phytohæmagglutinin (PHA), a crude extract from the bean *Phaseolus vulgaris*[11], was found suitable for this purpose. PHA is known to agglutinate red as well as white blood cells from many animal species. The addition of PHA to suspensions of lymphocytes stimulates cellular differentiation and proliferation[12]. The induction by PHA of lymphocyte-target cell aggregation and an aggregation-dependent target cell injury will be described in this article.

Primary cultures were set up from fœtal human kidneys (legal abortions) or from kidneys of new-born Sprague–Dawley rats after trypsinization (0·30 per cent trypsin in phosphate buffer, *p*H 7·6) of the minced tissue. The cells were grown in milk-dilution bottles, containing Eagle's medium[13] supplemented with 15 per cent heat-inactivated (30 min 56° C) calf serum and 100 I.U. of penicillin and 100 μg of streptomycin per ml. After 1–2 days, 2 μc. of thymidine labelled with carbon-14 (spec. activity 30·4 mc./mM, Radiochemical Centre, Amersham, England) was added and the incubation was continued for an additional 2–4 days. The cultures were finally washed twice with medium and the cells were afterwards removed from the bottles by treatment with trypsin. The cells were washed three times with cold medium. The number of living cells was determined by counting in a Bürker chamber, after staining with trypan blue. Monolayer cultures of HeLa cells were prepared in the same way.

Lymphoid cells were isolated from heparinized peripheral blood, taken from a cubital vein of normal persons or by heart puncture from normal Sprague–Dawley rats (randomly bred). Human lymphocytes were also isolated from lymph obtained from uræmic patients by drainage of the thoracic duct. An equal volume of 6 per cent dextran (Macrodex, Pharmacia, Sweden) was added to the blood and the red cells were allowed to sediment for 30–60 min at room temperature. After centrifugation at 400 r.p.m. for 5 min, the supernatant, containing white cells, was pipetted off and centrifuged at 1,500 r.p.m. for 5 min. Contaminating red cells were lysed by treatment of the sediment with 0·35 per cent sodium chloride for 1 min[14]. The white cells were suspended in Eagle's medium containing 5 per cent calf serum, and were allowed to stand for 1–2 h at room temperature, during which time most of the remaining granulocytes were adsorbed to the glass. Before use, the cell suspension consisting mainly of monocytes and lymphocytes was washed twice with medium.

		,,	Rat	358	14·6	383	2·9
			—	282	16·5	365	16·0

* All 6 samples of lymphoid cells in this column were obtained from different donors.

Varying numbers (1–10 × 10^6) of these white cells were mixed with labelled target cells (10^5) in roller tubes, suspended in Eagle's medium (5 per cent calf serum). The final volume of the incubation mixture was 1·5 ml.; 0·1 ml. of PHA-extract was added to some of the tubes. (The PHA-extract was prepared by extracting 40 g of crushed *Phaseolus vulgaris* beans with 200 ml. of 0·15 M phosphate buffer (*p*H 7·2) at 4° C for 24 h. The suspension was centrifuged at 4,500 r.p.m. for 30 min and the supernatant dialysed in the cold for 24 h against several changes of phosphate buffer.) The tubes were fitted loosely with screw caps, placed at 45° angle, and incubated at 37° C for 18 h in an atmosphere of air containing 5 per cent carbon dioxide.

After incubation, the tubes were centrifuged and the cell-free media were removed (supernatants I). In order to obtain a release of isotope from the damaged cells the sediments were treated with 0·25 per cent trypsin in phosphate buffer (*p*H 7·6) for 30 min at room temperature with occasional shaking[15]. After cooling with ice, the tubes were finally centrifuged at 2,000 r.p.m. for 6 min and the supernatants were withdrawn (supernatants II).

Deoxyribonucleic acid (DNA) was extracted from the supernatants and the cell sediments according to Schmidt–Thannhauser–Schneider[16]. After drying on plastic planchettes, isotope was determined at infinite thinness in a thin-window gas-flow counter (efficiency 10 per cent). The radioactivity (c.p.m.) released into supernatant II after trypsin treatment was expressed as per cent of the total radioactivity recovered in trypsin supernatant plus cells, and used as a measure of cell damage[15].

For morphological observations unlabelled target cells were incubated with lymphoid cells under the same conditions, but in Leighton-tubes containing coverslips. During incubation, the cells settled on the coverslips; these were then removed, washed once with phosphate buffer, fixed in methanol and stained with May–Grünwald and Giemsa.

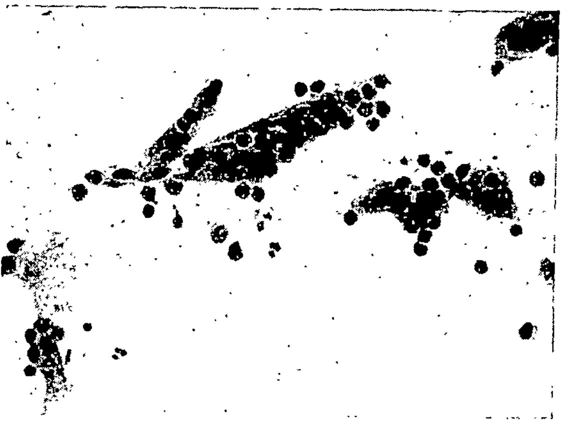

Fig. 1. Normal human lymphoid cells incubated with human fœtal kidney cells for 18 h in the presence of PHA (× 250)

The typical appearance of a culture of human fœtal kidney cells, incubated for 18 h with human lymphoid cells in the presence of PHA, is seen in Fig. 1. The aggregation of lymphocytes to each other and to target cells is striking. No such aggregation was observed in the absence of PHA (Fig. 2). Moreover, under the present conditions, PHA alone did not seem to affect the kidney cells.

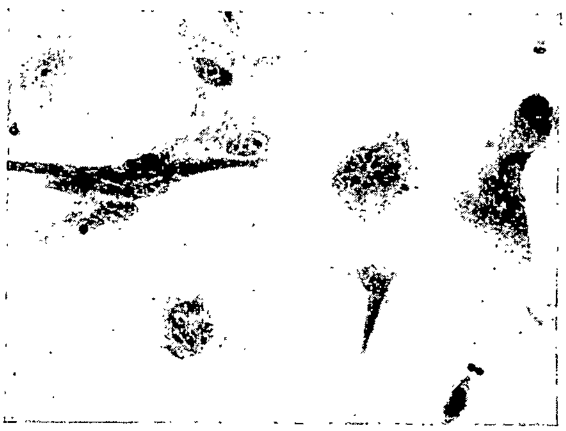

Fig. 2. Control culture from the same experiment as in Fig. 1. No PHA added (× 250)

Table 1 shows the cytotoxic effect of lymphoid cells from various sources, incubated with different target cells and PHA. As can be seen, regardless of the cell combinations used, isotope release was always higher in the presence of PHA than in its absence. However, the magnitude of this effect depended on the ratio of the lymphoid cells to the target cells. As a general rule, only a slight cytotoxicity was obtained with a ratio of 10 : 1, whereas a ratio of 100 : 1 gave a pronounced cytotoxic effect. A low ratio of lymphocytes to target cells may be an explanation of the weak cytotoxic effect seen in experiment 4, where the lymphoid cells were added to an unknown number of rat kidney cells, growing in monolayer culture. It will be noted that an increase of this ratio did not give rise to elevated cell damage in the controls, where PHA was absent. Under the experimental conditions used here, PHA alone caused no, or only negligible, damage of the target cells. (The contents of isotope in the incubation media (supernatants I) were variable, apparently depending on the health of the cells during cultivation[4]. However, since the release of isotope to supernatant I was not significantly elevated in the presence of PHA, it will not be discussed in this article.)

From these experiments it can be concluded that PHA induced a cytotoxic activity of the lymphoid cells.

In order to investigate whether or not these effects were due to the release of cytotoxic agents from the lymphoid cells, experiments were performed with lymphoid cells in 'Millipore' chambers. Normal human lymphoid cells (3×10^6) in 0·3 ml. of medium were placed in 'Millipore' chambers (diam. 14 mm, pore size 0·45μ), which were then incubated in Petri dishes with $1{\cdot}5 \times 10^5$ of human kidney cells in 5 ml. medium. The concentration of PHA was the same as in the experiments already described here. In some controls, PHA was omitted; in others the kidney cells were exposed to free lymphoid cells under similar conditions. Table 2 shows the results of a typical experiment. As can be seen, this arrangement prevented cell damage completely.

Table 2. EFFECT OF 'MILLIPORE' CHAMBERS (MC) ON THE PHA-INDUCED CYTOTOXICITY OF HUMAN LYMPHOID CELLS ON HUMAN FŒTAL KIDNEY CELLS

The lymphoid cell/target cell ratios (living cells) were 10 : 1. Time of incubation 18 h

Lymphoid cells	MC	PHA	Total radio-activity in DNA (c.p.m.)	Per cent released to Sup. II
+	+	+	453	7·8
+	–	+	743	14·5
+	–	–	957	6·2
–		+	1,244	7·9
–		–	928	6·2

In a second series of experiments, 100×10^6 human thoracic duct lymphocytes were grown in 10 ml. of medium for 24 h in the presence or absence of PHA. The media were then centrifuged and 1·5 ml. was added to 10^5 human fœtal kidney cells. No cell damage was observed after 18 h incubation (Table 3). Controls with living lymphocytes from the same donor gave positive results.

Table 3. EFFECT OF SUPERNATANTS FROM PHA-TREATED OR UNTREATED NORMAL HUMAN LYMPHOID CELLS ON HUMAN FŒTAL KIDNEY CELLS

Time of incubation 18 h

Lymphoid cells	Medium supplemented with	Total radioactivity in DNA (c.p.m.)	Per cent released to Sup. II
–	Sup. from PHA-treated cells	336	23·3
–	Sup. from untreated cells	289	20·6
+ *	PHA	181	38·6
+ *	—	358	21·2
–	PHA	329	22·8
–	—	300	25·8

* In these controls the lymphoid cell/target cell ratios (living cells) were 20 : 1.

These negative results are similar to those reported by other authors who used 'Millipore' chambers or various lymphocyte extracts in iso- and hetero-immune systems[7,10]. However, it is realized that cytotoxic agents, released from the lymphoid cells under these conditions, may become considerably diluted in the incubation medium. In contrast, when lymphoid cells are aggregated to target cells, cell damage may be produced, because of high local concentration of such agents in the contact areas between the cells[17].

Although the results presented here underline the importance of close contact between lymphoid cells and target cells in order to produce damage of the latter, they do not disclose how this injury is brought about. The simplest explanation would be to ascribe an entirely passive role to the lymphoid cells. Hence, one could envisage the target cells being damaged by the blocking of their surfaces by the lymphoid cells, thus depriving them of nutrients or inducing various metabolic disturbances. Although unlikely (cf. ref. 8), an explanation of this sort cannot yet be ruled out.

Alternatively, one could expect the lymphoid cells to play an active part in producing cell damage. The observation made in an isoimmune system, that hydrocortisone inhibits the cytotoxicity of immune lymphocytes but not their aggregation to target cells, would perhaps speak in favour of this assumption[18]. If this were the case, one may ask whether or not cytotoxic activity of the lymphoid cells was induced solely by their contact with the target cells, the contact being mediated by PHA in some unknown manner. However, when lymphoid cells from normal mice were non-specifically aggregated to mouse fibroblasts in monolayer by means of polylysine treatment, no obvious cell damage of the target cells was observed under the microscope[10]. If these findings can be confirmed and extended to other experimental systems, they would suggest that the injury of the target cells, in our experiments, could be an expression of a more general stimulation of the lymphoid cells by PHA, related to its mitogenic activity[19].

Obviously, it cannot be decided at present whether or not the target-cell injury observed in these experiments reflects the induction in the lymphoid cells of an immune response[20,21], possibly potentiated by PHA[15]. However, since target cells and lymphoid cells in our experiments were obtained from histoincompatible animals or human beings, experiments with inbred, histocompatible animals should throw some light on this point. Such experiments are in progress.

This work was supported by a grant from the Swedish Life Insurance Companies' Fund for Medical Research.

RADIATION-INDUCED CHANGES IN METABOLISM OF THYMINE IN RAT

By T. H. BATES, CHRISTINE I. SMITH and DR. HYLTON SMITH

U.K. Atomic Energy Authority, Chapelcross Works, Annan, Dumfriesshire, Scotland

IN an examination of the effects of X- and γ-irradiation on human beings, it was observed that increased urinary excretion of β-amino-isobutyric acid (BAIBA) occurred in some, but not all, patients[1]. Metabolism of the BAIBA precursor, thymine, is still obscure, but degradation occurs predominantly in the liver. Since human beings possess only a limited ability to destroy BAIBA, Armstrong *et al.*[2] suggest that the excessive excretion of BAIBA in normal people, where there is no evidence of marked tissue destruction, could reflect impairment of liver function. Thus the possibility exists that changes in liver function may have modified the excretion pattern in the patients examined by us. In order to evaluate this point, radioactive thymine was administered to irradiated rats and the excretion of radioactive metabolites was determined.

In an initial experiment, 14 Sprague–Dawley female rats were exposed to varying amounts of X-irradiation (0–803 r., 250 kV, 15 m.amp, 1 mm copper/1 mm aluminium filter) to total body. Urine was collected for 2 days before and 5 days after irradiation, and each sample was analysed for BAIBA by the method of Smith and Dymond[3]. The results in Table 1 show that the mean daily output of BAIBA did not differ between the pre- and post-irradiation periods—furthermore, no correlation existed between BAIBA excretion and irradiation dose.

Table 1. EFFECT OF X-IRRADIATION ON EXCRETION OF BAIBA IN THE RAT

Rat	Dose of X-radiation (r.)	Daily output of BAIBA in μM (pre-irradiation)	Daily output of BAIBA in μM (post-irradiation)

In man, thymine is first reduced to dihydrothymine. This is hydrolysed in two steps to β-ureido-isobutyric acid and finally BAIBA[4]. Pyrimidine ring cleavage occurs on the formation of β-ureido-isobutyric acid. BAIBA is then probably transaminated to form methyl malonic acid semi-aldehyde which is degraded via pyruvate and the tricarboxylic acid cycle. The pathway is similar in rat although there appears to be a reduced ability to convert thymine to dihydrothymine[5].

By using two differently carbon-14 labelled forms of thymine, it is possible to compare rates related to the formation and to the destruction of BAIBA. Thymine-2-^{14}C is metabolized with the liberation of $^{14}CO_2$ at the pyrimidine ring cleavage, whereas thymine-5-^{14}C does not produce $^{14}CO_2$ until decarboxylation of its metabolites in the tricarboxylic acid cycle. Thymine-2-^{14}C, obtained from the Radiochemical Centre, Amersham, was administered intraperitoneally to two groups of rats. One group served as the control. The other group was irradiated, several hours prior to injection of the thymine, with 2,000 rads to upper abdomen only. Each animal was given 1 μc. in 13 μg thymine and then placed in a metabolic unit which was continuously purged with air free of carbon dioxide and the latter in expired gases was collected by absorption in primene solution. $^{14}CO_2$ was determined by mixing an aliquot of this solution with *NE*213 liquid scintillator and assaying in an Ekco *N* 664*A* counter. The excretion of $^{14}CO_2$ was found to be similar in irradiated and non-irradiated groups, 90 per cent of the injected radiocarbon being recovered in the expired air within 4 h after injection. Thus the degradation of thymine to the point of ring cleavage was not affected by liver damage as a result of irradiation. Thymine-5-^{14}C was synthesized by the method of Henderson, Fink and Fink[6] with certain modifications. Using sodium propionate as starting material, these authors produced thymine labelled in the methyl group. In our synthesis, sodium propionate-2-^{14}C was converted to ethyl propionate. This was condensed with diethyl oxalate in the presence of sodium ethoxide to form the sodium salt of diethyl methyl oxosuccinate. Reduction of this by catalytic hydrogenation gave the ethyl ester of β-methylmalic acid which was saponified and finally condensed with urea in concentrated sulphuric acid to yield thymine. The product was salted out into methyl alcohol from the neutralized reaction mixture. The specific activity was 0·875 μc./mg and 0·07 μc. in 80 μg was administered to each animal of three groups. The first group acted as control,

Table 2 DISTRIBUTION OF CARBON-14 AT 5 DAYS AFTER THYMINE-5-^{14}C ADMINISTRATION

Treatment	Carbon-14 injected (per cent) Combined urines	Liver	Intestine
Control	14·4	2·4	3·8
Total-body irradiation (350 rads)	18·7	1·3	7·7
Upper abdomen (1,500 rads)	34·9	2·9	2·8

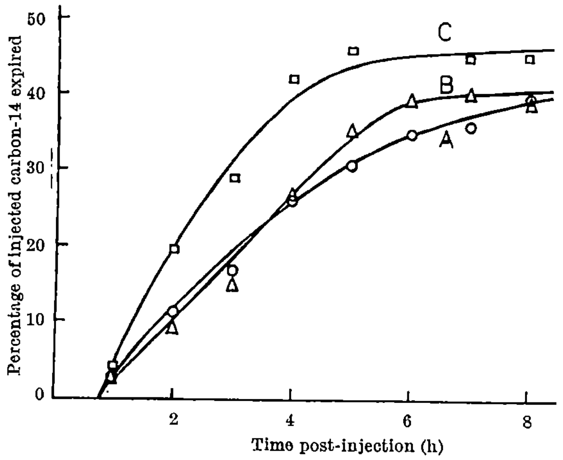

Fig. 1. Expiration rate of $^{14}CO_2$ resulting from the catabolism of thymine-5-^{14}C
A, control; *B*, total-body irradiated (350 rads); *C*, upper abdomen irradiated (1,500 rads)

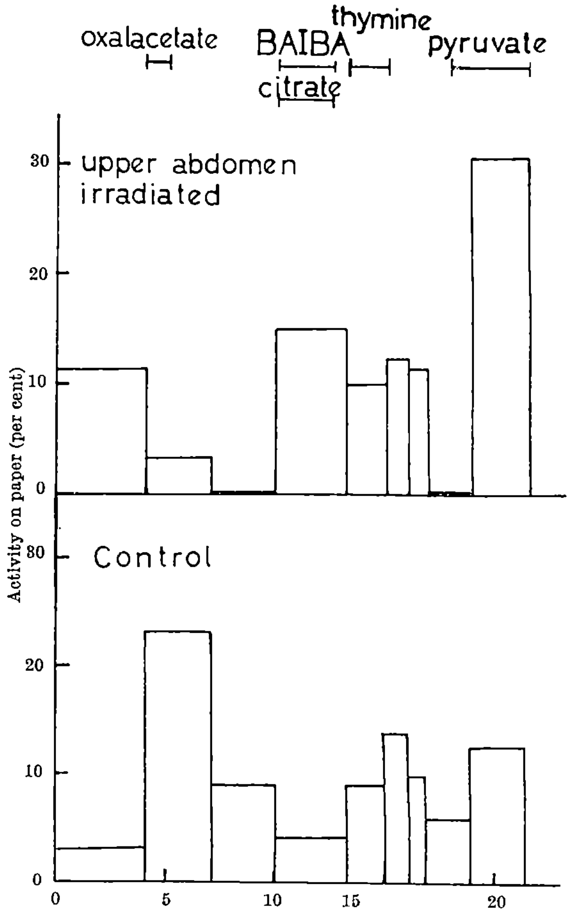

Fig. 2. Effect of irradiation on the distribution of carbon-14 compounds in rat urine
The positions of the migration bands of five substances are indicated. Solvent mixture, butanol : formic acid : water = 77 : 10 : 13

and the other groups were irradiated, 24 h prior to injection, with either 350 rads to total body or 1,500 rads to upper abdomen only. The 24-h delay allowed the development of biochemical injury before the introduction of thymine-^{14}C into metabolic pools. In addition to expired air, all urine was collected for five days after the thymine injection. After this period, the animals were killed and tissues analysed for carbon-14 content by combustion using an oxidation train incorporating a silver/vanadium oxide catalyst; the carbon dioxide was absorbed in primene solution. The results are shown in Table 2 and Fig. 1.

Within the first 8 h 45 per cent of the carbon-14 had been released as $^{14}CO_2$ in expired air and during the next four days 18 per cent was excreted by this route. The amount of $^{14}CO_2$ was similar in control and irradiated groups although the rate of release may have been higher in the irradiated groups. In the five post-injection days more than twice as much carbon-14 activity was found in the urine of the liver-irradiated group than in the controls. Chromatographic analysis (ascending, butanol/formic acid/H_2O, 77 : 10 : 13) followed by radio-assay of the separated bands revealed a significant difference in the distribution of activity on the papers. Identification of the areas of activity is tentatively ascribed as shown in Fig. 2. Analysis of control urine showed that the carbon-14 was associated with urea and metabolites of the Krebs cycle, whereas the activity in the liver-irradiated group was associated predominantly with a fast-moving, ultra-violet absorbing band, believed to be pyruvate. No accumulation of BAIBA occurred after irradiation and there appeared to be a decrease in the amount of radioactive urea formed. This was confirmed by comparing activities of urines before and after incubation with urease. The concomitant accumulation of pyruvate after irradiation is in agreement with the work of Rust[7], who associated the increase in pyruvate with increased glycogenesis after irradiation.

It is suggested in conclusion that irradiation involving moderate liver damage does not alter the rate of catabolism of thymine to BAIBA, but thereafter, accumulation of the metabolites of BAIBA occurs with the formation of carbohydrates as pyruvate builds up. These carbon-14 carbohydrate compounds are gradually metabolized during 4–5 days after the injection with the liberation of carbon-14 compounds predominantly in the urine.

We wish to thank Mr. G. S. Weir for carrying out the synthesis of thymine-5-^{14}C.

GALACTOSE-1-PHOSPHATE URIDYL TRANSFERASE ACTIVITY IN GALACTOSÆMIA

By WON GIN NG*, DR. WILLIAM R. BERGREN and GEORGE N. DONNELL

Departments of Biochemistry and of Pediatrics, School of Medicine, University of Southern California:
Biochemistry and Metabolic Research Divisions, Children's Hospital, Los Angeles

THE presence of some degree of galactose-1-phosphate uridyl transferase activity in galactosæmia has been suggested by a number of investigators. The work recorded here, based on an examination of intermediates of galactose oxidation, provides further evidence for the incompleteness of the enzymatic block.

Using a manometric procedure, Schwarz *et al.* found no demonstrable erythrocyte transferase activity in 10 of 23 galactosæmic children, but in the remainder an activity averaging 7 per cent of normal value was found[1]. Hsia *et al.*, on the basis of direct measurement of enzyme activity, also concluded that a low degree of activity was present in some patients[2]. Segal *et al.* have examined *in vivo* utilization of injected carbon-labelled galactose[3]. Recovery of carbon label in exhaled carbon dioxide was comparable to normal controls in two of eight galactosæmic individuals. In a separate *in vitro* investigation by Weinberg[4], whole blood and leucocytes from one of these individuals was able to convert galactose-1-^{14}C to labelled carbon dioxide at a substantially greater rate (12–15-fold) than observed with other galactosæmics in his group. However, the amount of galactose oxidized was only 5–8 per cent of normal. Erythrocyte transferase activity could not be demonstrated in any of the galactosæmic subjects, and Weinberg suggested that an alternate pathway might be operative in the unusual case, perhaps the uridine diphosphogalactose pyrophosphorylase system described by Isselbacher[5].

In addition to the patients previously reported, Isselbacher has found substantial *in vitro* production of carbon dioxide from labelled galactose by erythrocytes from two galactosæmic individuals of 20 and 11 years of age, respectively[6].

We have applied a modification of Weinberg's *in vitro* procedure to our own galactosæmia patients, including affected sibling pairs in five families. The results are shown in Table 1. The expected difference in carbon dioxide production between whole blood from galactosæmics and from normals was found, but three points are of particular interest. First, there was variation among galactosæmics in the capability of their blood cells to produce carbon dioxide from galactose. Secondly, three individuals differed markedly from the remaining ten. Thirdly, correspondence of values in sibling pairs suggested a familial influence.

Table 1. *In vitro* OXIDATION OF GALACTOSE-1-^{14}C BY WHOLE BLOOD*

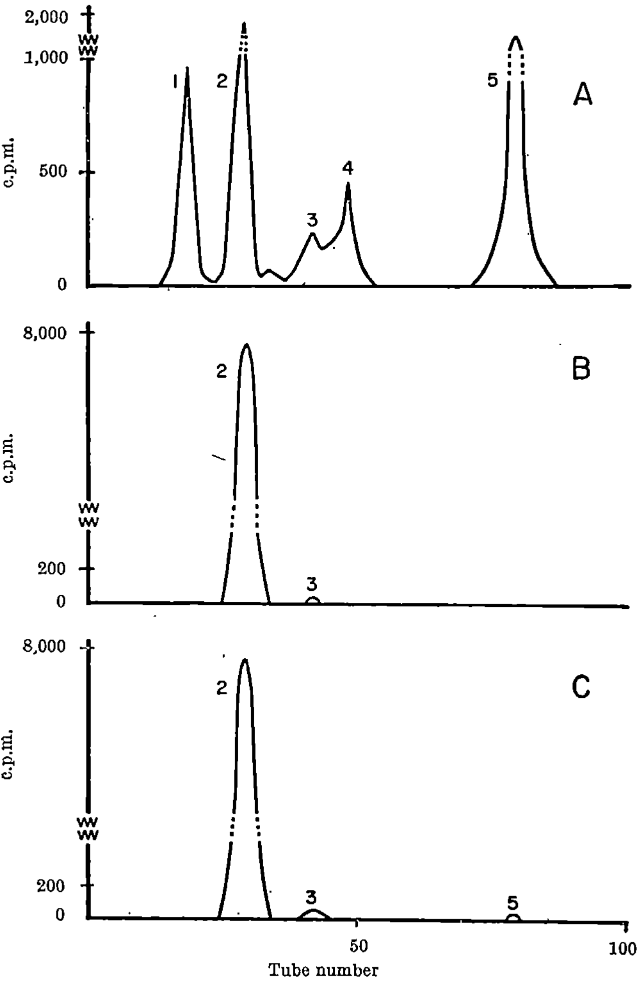

Fig. 1. Column chromatography of galactose intermediates. *A*, pattern for blood from normal person; *B*, from the usual galactosæmic patient; *C*, from one of the unusual galactosæmic individuals. The peaks represent components as follows: 1, lactic acid; 2, galactose-1-phosphate; 3, UDPHexose; 4, triose phosphate (and other compounds as yet unidentified); 5, diphosphoglyceric acid

obtained were incubated in the same manner as whole blood, utilizing the same labelled galactose pool. The relationships among the results were similar to the findings on whole blood. The amounts of labelled carbon dioxide produced by leucocytes from individuals 8*a* and 8*b* were almost negligible. In the case of individual No. 1, one of the unusual cases, the counts were substantially higher, but 20-fold less than produced by leucocytes from a normal control.

To examine for individual differences in more detail, labelled intermediates in the residue after incubation of whole blood with galactose-1-^{14}C were separated by gradient elution of 'Dowex-1-formate' columns[7]. Typical results are shown in Fig. 1. After incubation of blood from normal individuals, the principal labelled peaks, in order of emergence from the column, correspond to lactic acid, galactose-1-phosphate, uridine diphosphohexose (UDPHexose), triose-3-phosphate (and other compounds unidentified as yet) and finally diphosphoglyceric acid (DPGA). In the galactosæmia patients, the anticipated large amount of galactose-1-phosphate was found. Unexpectedly, a peak in the UDPHexose region also was obtained consistently. In the usual type of galactosæmic subject (less than 200 c.p.m. of labelled carbon dioxide), the amount of UDPHexose was very small. However, in the three unusual galactosæmics examined (1,306–1,829 c.p.m.), the UDPHexose peaks were markedly larger, and an additional small peak in the diphosphoglyceric acid area was present.

To determine the identity of the compounds in the UDPHexose region, appropriate eluates were concentrated by lyophilization. After adsorption on charcoal, labelled compounds were eluted with 50 per cent ethanol containing 0·1 per cent ammonia. This procedure was carried out separately for normal controls and for the three unusual galactosæmics. It was necessary to pool column eluates from several experiments for the usual galactosæmics. In all instances, on paper chromatography with ammonium acetate–ethanol at *p*H 7·5 (ref. 8), the radioactive material migrated to the same region as did known UDPGlucose or UDPGalactose. After acid hydrolysis and chromatography with pyridine–butanol–water[9], both labelled galactose and labelled glucose were identified. All galactosæmia bloods showed a ratio of glucose to galactose of 2 to 1: in contrast, the ratio for normal bloods was 1 to 3. These results reflect the relative differences in transferase and epimerase activity in the two groups under the non-equilibrium condition of the experiments. The presence of carbon label in the glucose, and also in the DPGA region of the column effluents, confirms their origin to be from galactose.

Erythrocyte galactose-1-phosphate uridyl transferase activity could not be detected by a UDPGlucose consumption assay[10] in any of the galactosæmic subjects investigated. The presence of carbon label in UDPHexose suggested either that the transferase assay used is not sufficiently sensitive to detect very low levels of transferase activity or that the UDPHexose was formed by some other route.

Isselbacher has described an alternate pathway for galactose utilization in liver by way of UDPGalactose pyrophosphorylase, an enzyme capable of converting galactose-1-phosphate to UDPGalactose in the presence of uridine triphosphate (UTP)[11]. Although Isselbacher has stated that this enzyme does not occur in erythrocytes[12], it was desirable to re-examine the possibility in the present connexion. Hæmolysates of erythrocytes from normal individuals, galactosæmia heterozygotes, and galactosæmics (including two of the three individuals with relatively high production of carbon dioxide) were incubated with galactose-1-^{14}C-1-phosphate, both in the presence and absence of UTP[11]. Labelled UDPHexose formed was measured and the results are shown in the first column of Table 2. No incorporation of label into UDPGalactose could be detected with hæmolysates from galactosæmic individuals. Incorporation was found with normal hæmolysates and to some extent with those from galactosæmia heterozygotes. By themselves, these results might indicate that UDPGal pyrophosphorylase activity is present in normal hæmolysates and in those from galactosæmia heterozygotes but not at all in those from galactosæmia homozygotes. If this were to be true, it

* Incubation mixture contained 0·2 μmoles Gal-1-^{14}C-1-P (15,000 c.p.m. in liquid scintillation system), 0·4 μmoles UTP, 5 μmoles $MgCl_2$, 0·4 m.moles glycine buffer (*p*H 8·1), Glu-1-P at final concentration as indicated, and 0·3 ml. of freshly prepared 50 per cent hæmolysate with total volume of 1 ml. Incubation period was 30 min at 37°. Isolation of UDPHexose by charcoal adsorption was in accord with a previous paper (ref. 16).

† Net increase over control without UTP.

would be necessary to postulate an additional enzymatic defect in galactosæmia.

A more likely explanation can be based on the conditions of the assay. Isselbacher has pointed out that apparent UDPGalactose pyrophosphorylase activity can result from a sequence of reactions involving glucose-1-phosphate, UDPGlucose pyrophosphorylase and transferase[11].

$$\text{G-1-P} + \text{UTP} \xrightarrow[]{\substack{\text{UDPG}\\ \text{Pyrophosphorylase}}} \text{UDPG} + \text{PP}$$

$$\text{UDPG} + \text{Gal}^{*}\text{-1-P} \xrightarrow{\text{Transferase}} \text{UDPGal}^{*} + \text{G-1-P}$$

The labelled UDPGal* produced would be indistinguishable from that arising from the reaction:

$$\text{Gal}^{*}\text{-1-P} + \text{UTP} \xrightarrow{\substack{\text{UDPGal}\\ \text{Pyrophosphorylase}}} \text{UDPGal}^{*} + \text{PP}$$

Since UDPGlucose pyrophosphorylase activity was found to be present in the hæmolysates used in this investigation[13], controls containing added glucose-1-phosphate were included (second column of Table 2). The addition of glucose-1-phosphate had no influence on the assay with galactosæmia hæmolysates, but it led to a marked net increase of incorporation (that is, in the presence of UTP) of galactose-1-^{14}C label into UDPHexose both with normal and with galactosæmia heterozygote hæmolysates at a glucose-1-phosphate concentration of 2×10^{-5} M. These results suggest that the incorporation found reflects the presence of galactose-1-phosphate uridyl transferase and that it does not represent a separate UDPGalactose pyrophosphorylase activity in erythrocytes. The difference in values between the normal and the galactosæmia heterozygote groups further suggests that this is the case. An estimated native glucose-1-phosphate level of 5×10^{-4} M in erythrocytes[14] could account for the incorporation recorded in column 1 of Table 2.

The present results are concordant with Isselbacher's earlier statement concerning the lack of UDPGalactose pyrophosphorylase activity in erythrocytes. The formation of labelled UDPHexose on incubation of galactosæmia erythrocytes with galactose-1-^{14}C must rest on some other basis. It appears that the enzymatic block in galactosæmia is incomplete. Any other explanation for the presence of carbon label in UDPHexose (and DPGA) under the experimental conditions seems remote. On the basis of the data, it cannot be decided if galactose-1-phosphate uridyl transferase activity is greatly reduced or if a modification in the enzyme is involved.

Recently, Segal *et al.* have discussed the possibility that during childhood some galactosæmia patients acquire an ability to metabolize galactose[15]. The present findings suggest, however, that galactose-1-phosphate uridyl transferase activity may be present in small, but varying, amount in all galactosæmics, possibly from birth. The ability of erythrocytes of some galactosæmics to produce carbon dioxide from galactose appears to be an inherited rather than acquired character.

REDUCTION IN RATE OF GROWTH OF HAIR IN MICE AS AN INDICATOR OF EXPOSURE TO CHRONIC LOW DOSAGE IONIZING RADIATION

By D. C. CHOW, PROF. S. ROTHMAN, DR. A. L. LORINCZ, DR. F. MALKINSON
and A. SANDBURG

Argonne Cancer Research Hospital*, Department of Medicine (Section of Dermatology),
University of Chicago, and U.S. Air Force Radiation Laboratory, Chicago

PRESENT-DAY biological criteria for assessing damage caused by chronic exposure to ionizing radiation include evaluation of one or more of the following: life-span shortening, mortality rate, cataract formation, hæmatological changes, incidence of tumours, and changes in certain enzyme activities[1–4]. Many of these changes develop slowly over long periods of time and require prolonged study of large numbers of animals. In this study observations are reported which indicate that, in mice, the rate of regrowth of hair after plucking is a sensitive, rapid and simple, dose-dependent biological index to damage caused by chronic, low dosage ionizing radiation.

CF No. 1 female mice which were 7–8 weeks old at the onset of irradiation were used in all experiments. Every time animals were taken out of the irradiation facilities for examination of hair growth, a suitable number of non-irradiated animals were removed from the next room to serve as controls.

Details of the chronic fast neutron and γ-radiation facilities, and the dosimetry for the various exposure positions within each facility, have been described previously[5,6]. In brief, the γ-exposures were given by means of a 10-c. cobalt-60 point source, and the fast neutron exposures were administered by using a 100-c. plutonium–beryllium line source. In the work described here, the animals in groups of 12 were exposed for 10 h each day (9 p.m. to 7 a.m.) in metal or plastic cages placed radially around the sources. The radiation exposure was initiated by elevating the source from its storage pit into the centre of the cage-array, and the duration of each exposure was controlled by appropriate timing mechanisms which, in turn, controlled the source-hoisting motors. The animals remained in the exposure facility during the 14-h period when the sources were shielded, since Health Physics surveys indicated that radiation exposure was negligible under these conditions. Food ('Rockland Laboratory Diet') and water were available at all times. The radiation-dose at each of the exposure positions in the γ facility was determined with Victoreen ionization chambers, which were calibrated against a radium standard and against a National Bureau of Standards calibrated chamber. Various chemical dosimeters were also used to verify the radiation dosimetry within this facility. The fast neutron dosimetry is based primarily on the specifications provided by the manufacturer, although additional measurements have been carried out with chemical dosimeters, with foils, and with a Hurst proportional counter. The γ-contamination within the fast neutron facility was estimated by using a neutron-insensitive chemical system, and proved to be negligible for this study.

* Operated by the University of Chicago for the U.S. Atomic Energy Commission.

In all animals, a 2 cm × 1·5 cm area on the mid-dorsal region was epilated by hand-plucking to induce anagen, that is, the growing phase of the hair cycle. The animals were then observed daily until a uniform sheen of new hairs appeared on the skin surface, which ordinarily occurred after 8–10 days. A small area of uniform new hair growth on each animal was outlined with a coloured marker, and 6 days later the hair was again plucked by hand from within the demarcated area. 300–400 of the plucked hairs were then placed in a Petri dish and floated on a small amount of water. Under a dissecting microscope, the four hair types of the mouse as indicated in Fig. 1 could easily be identified[7]. Intact, awl hairs were isolated and picked up with ophthalmological forceps and arranged parallel to one another on a standard 3·25 × 4 in. lantern-slide glass plate. A 4 cm × 1 cm strip of translucent graph paper (Keuffel and Esser No. 359*T*-14*LG*) was also placed on the glass plate which was then covered with another plate of the same size. After taping the two plates tightly together, the resulting 'slide' was projected on to a screen giving an approximately 19-fold image enlargement.

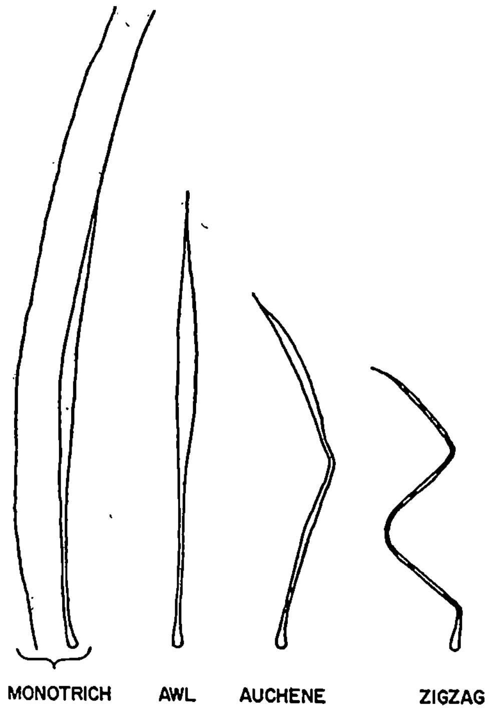

Fig. 1. Dry's four types of hair in mice

In the magnified images, hairs damaged slightly in plucking could easily be recognized. About 10 per cent of the mounted hairs were so damaged and excluded from measurement. For each animal, the lengths of 35 straight hairs with intact anagen bulbs were measured with a Swiss map plan measure (Charles Bruning Company Inc., Mount Prospect, Illinois, Catalogue No. 2375). Actual hair lengths were calculated by correcting their measured magnified lengths according to the magnification factor of the projected unit scale.

The animals irradiated with the cobalt-60 source received 31·3 r. daily doses of γ-radiation for varying periods of time. At the time of the first epilation, that is, 24 h after termination of irradiation, different groups of animals had accumulated total doses of 783–3,881 r. at the rate of 31·3 rads/day.

Table 1 shows that significant impairment of hair growth after induction of anagen is first observed after a total dosage of 1,064 r. has been accumulated, and increases in dose-dependent fashion at higher total dosage levels.

Table 1. Retardation of Hair Growth in Animals given 10-h Daily Doses of 31·3 r. γ-Radiation in the 10-c. Cobalt-60 Irradiation Facility

Group No.	No. of animals examined	Total dose of radiation received (r.)	Mean length of hair for group (mm)	Percentage retardation
GN-C	48	Nil	7·113 ± 0·036	—
G-I	8	783 (in 25 days)	7·033 ± 0·077	—
G-II	7	1,064 (in 34 days)	6·531 ± 0·061	8·1
G-III	7	1,314 (in 42 days)	6·045 ± 0·026	14·9
G-IV	4*	2,254 (in 72 days)	5·713 ± 0·054	19·6
G-V	7*	3,881 (in 124 days)	5·230 ± 0·030	26·4

* Three of 7 animals irradiated in Group *G*-IV and 7 of 14 in *G*-V died before completion of the experiment.

The animals irradiated with the 100-c. plutonium–beryllium source received varying doses (35–595 rads) of fast neutron radiation at the rate of 3·18 rads/day. Table 2 shows that, in these animals, the rate of hair growth is clearly retarded by fast neutrons at a total dose of 80 rads. From there on, the hair growth rates are progressively impaired as total dose increases.

Table 2. Retardation of Hair Growth in Animals given 10-h Daily Doses of 3·18 rads Fast Neutron Radiation in the 100-c. Plutonium–Beryllium Irradiation Facility

Group No.	No. of animals examined	Total dose of radiation received (rads)	Mean length of hair for group (mm)	Percentage retardation
GN-C	48	Nil	7·113 ± 0·036	—
N-I	9	35 (in 11 days)	7·081 ± 0·051	—
N-II	8	80 (in 25 days)	6·650 ± 0·042	6·4
N-III	8	117 (in 37 days)	6·529 ± 0·061	8·2
N-IV	7	229 (in 72 days)	6·228 ± 0·081	12·4
N-V	7	394 (in 124 days)	5·926 ± 0·023	16·6
N-VI	6	595 (in 187 days)	5·574 ± 0·034	21·5

Variations in length of hair in individual animals were always less than 1·5 per cent of the mean length and variations of the mean hair lengths between different animals in any one group were always under 1 per cent.

In the lower dosage ranges, where the general condition of the animals remained good, the relative biological effectiveness of chronic fast neutron radiation in retarding mouse hair growth was about 9 times that of γ-radiation. At the higher dose-levels this relative biological effectiveness was observed to drop sharply to about 4. The generally impaired nutritional state of these animals, together with smaller increments of hair growth retardation at these higher dosages, may account for this difference.

The quite substantial retardation of hair growth, at a dose-level as low as 80 rads of fast neutron radiation given in 25 days, is noteworthy in view of the absence of other gross signs of radiation damage in these animals. It is also of interest that microscopic examination of hairs at all dosage-levels studied failed to show dysplastic changes[8,9].

This work indicates that measurement of hair growth rates serves as an early, sensitive and simple, dose-dependent index to chronic low dosage radiation. Further studies of the duration and degree of reversibility of these hair growth effects might be of interest. In addition, manifestation of these effects can be recognized early, and large numbers of animals are not required for statistically valid data.

This work was supported (in part) by USPHS general research support grant 1–*S*01–*FR*–05067–01.

EMPEROR PENGUINS AT CAPE CROZIER

By Dr. BERNARD STONEHOUSE
Department of Zoology, University of Canterbury, Christchurch, New Zealand

THIS article discusses recent changes in the colony of emperor penguins (*Aptenodytes forsteri* Gray) at Cape Crozier, Ross Island (77° 25′ S., 167° 50′ W.), in the Ross Dependency, Antarctica. The colony was discovered by Lieut. Skelton, of Scott's party, in 1902. Its position on sea ice at the foot of the Ross Barrier was recorded first by Scott[1] and later in more detail by Wilson[2]. The subsequent history of the colony has been summarized by Caughley[3] and Budd[4], who have also discussed reasons for changes in its status and success. My own censuses of the colony in 1961–63 suggest that the changes are more marked than earlier evidence indicated, and are closely linked with movements of the main Barrier cliff at Cape Crozier. These investigations are part of a long-term conservation programme sponsored by the University of Canterbury.

Table 1. EMPEROR PENGUIN ADULTS AND CHICKS AT CAPE CROZIER, 1902–63
Numbers of dead chicks are shown in brackets

Date	Chicks	Adults	Ref.
18.10.02	30 (80)	400	1 (490)
8.11.02	0	—	1 (490)
12. 9.03	150 (18)	1,000	1 (491)
2.11.03	30 (63)	400	2 (10)
20. 7.11	25–50	100	10 (39)
23. 9.57	100–270	700–800	3 (252)
26.11.58	523 (58)	618	3 (255)
25.10.61	1,325 (101)	Over 2,000	Stonehouse (in the press)
4.12.62	1,250 (30)	1,000–1,200	,, ,,
20.11.63	805 (12)	1,050–1,300	,, ,,

Table 1 summarizes counts of chicks and adults on the colony since 1902. Even in its present state of prosperity the colony is small compared with some of the more northerly ones[5]: during the first decade of the century it may have been close to extinction. Comparisons of counts from different years may be made only with caution. Adult numbers vary with time of year, being high during courtship (late May and June at Cape Crozier), low in incubation (July to September) when only males are present, higher again when the females return in August and September, and variable in spring and early summer when chicks are being fed, young non-breeding adults are present, and casual visits are paid by parents which lost egg or chick earlier in the season. The adults, which are highly social, enter and leave the colony in groups, assemble in parties away from the colony (where they may easily be missed in a rapid count) and tend to travel only on fine days. Some further difficulties encountered in censusing adult emperor penguins are described by Budd[4]. Chick counts are more reliable, especially toward the end of the breeding season (October to December) when counting is easy and mortality low. Their value as indicators of population size increases when figures for two or three consecutive seasons are known, as winter mortality of eggs and chicks can be high in certain seasons: thus at Cape Crozier in 1903, September and October blizzards killed more than two-thirds of the chick population[2]. A reasonably stable population should, during a number of years, provide a consistent upper level of chick numbers late in the season, representing a minimal value for the number of breeding birds in the colony. Ideally, both chicks and adults must be counted as accurately as possible over a number of years before the true status of a colony can be determined.

Cape Crozier can now be reached in 30 min by helicopter from New Zealand and American bases in McMurdo Sound, and the Canterbury unit visits each spring for counting. In fine weather (a prerequisite of a flying visit) the assembly of chicks is herded gently into a slowly moving column and counted by at least two observers; a confirmatory count is taken as the chicks return to their original site. The mean value is likely to be accurate within 2–3 per cent. Dead chicks and abandoned eggs are also counted, but others may remain undetected under snow drifts below the ice cliffs. Adults are counted on the ground and from the air, but their dispersal over several square miles of sea ice may lead to counting errors of up to 20 per cent. Interesting comparisons with earlier accounts of the colony are already emerging from these brief annual visits.

When first described in 1902, the colony was very small and situated on sea ice under the high, seaward-facing cliff of the Ross Barrier. A shallow bay in the cliff offered some protection from southerly and south-easterly winds, but the colony site was open to the north and vulnerable to the disrupting influence of swells with a northerly component. The 1902 position appears in Skelton's photograph[6], and details of the junction between ice cliff and Ross Island appear in Debenham's report (ref. 7, map II inset), from which Fig. 1 of this article is taken. New sea ice fills the foreground of Skelton's photograph. The small number of chicks and disproportionately large number of adults present on the colony in both 1902 and 1903 were noted by Wilson[2]; his interpretation, that only one in ten of the breeding birds laid each year, has not received support from observations in other colonies[8,9]. The position of the breeding group at the edge of older sea ice suggests that a break-out in winter had already removed some of the breeding birds and chicks, and many of the bystanders were therefore likely to be bereaved adults whose eggs or chicks had drifted away and perished. Budd's[4] estimate of an original breeding population of 500–1,000 pairs covers our scant knowledge of the movements of adults in these circumstances. Assuming that each chick in September 1903 was accompanied by a single parent, and that the remaining adults represented three-quarters of the bereaved parents, a breeding colony of some 700 may be postulated for that year. The 1902 population is unlikely to have differed by more than 5–10 per cent, so that catastrophes involving between 75 and 95 per cent of the annual crop of eggs and chicks must have occurred between June and October of both years.

There is more direct evidence for a similar catastrophe in 1911. During the intervening years the ice cliff advanced more than a quarter of a mile at Cape Crozier (Fig. 1), eliminating the shallow bay and leaving the colony more than ever exposed to the sea and to the disrupting effect of swells. From his July visit, Wilson[10] concluded that the ice supporting the colony had already broken and re-formed, probably with the loss of part of the annual crop of eggs. The three eggs collected during his visit yielded embryos which were estimated by Glenister[11] to have been laid about the beginning of July, close to the peak period of laying postulated by Stonehouse[8] for this colony.

Thus the early position of the colony under the face of the Ross Barrier appears to have been precarious in the extreme. It is doubtful if the colony could for long have maintained its numbers in these circumstances, and the population may well have declined between 1902 and 1911. Its position before 1902 cannot be determined with any certainty, although the disparity between numbers of chicks and adults in that year suggests that breeding success had been higher in the immediate past. Wilson[6] compared the ice cliff with that shown in Bernacchi (ref. 12, plate 17), taken in 1899, and directed attention to remnants of shelf ice under the cliffs at Cape Crozier; the two pieces of evidence indicated to him that the barrier had recently retreated and the small bay of 1902–03 was newly formed. Bernacchi's map[12], based on Admiralty charts, certainly shows the end of the Barrier in a position well to the north of the cliffs at Cape Crozier, but the scale is small and its accuracy cannot be assumed. Colbeck's chart from the same expedition[13] shows the Barrier starting well to the south of 'Cape Crozier', although the outline of the land cannot be reconciled with modern maps.

The colony was visited by Balham in 1957 and Caughley in 1958. Both observers found it more favourably situated, in a deep enclave of sea ice behind the main cliff of the Ross Ice Shelf[3]. Many more chicks were present than on any of the earlier visits. Caughley estimated that the shelf had advanced two miles since 1911. The western end of the Barrier, which in 1903 lay to the south of the Knoll (a prominent point overlooking the colony site) and in 1911 pressed hard against the steep cliffs of Cape Crozier, had by 1958 passed north of the knoll and developed a prominent east–west split, partly separating a large frontal block from the main body of shelf ice. The advance has continued to the present day, and a second split or enclave has developed. Fig. 2, based on a recent map (N.Z.M.S. 175/16, 1962), shows the position of enclaves and colony in 1960 and 1961. The 1962 and 1963 positions of the colony were similar, and correspond with the position shown by Caughley for 1958. The more southerly of the two enclaves, which was not present in 1958 (Caughley, personal communication), may have widened slightly since 1961. The Barrier face now lies some 2·75 miles north of the Knoll, marking a total advance of nearly four miles from the 1902 position.

Since 1958 (and possibly some years before) the colony has formed each year under the north-facing cliff of the wider enclave, where it finds shelter from prevailing southerly and south-easterly winds. An interesting feature is its annual movement away from the sea during the incubation or guard stages, as shown by a succession of guano-stained patches on the smooth sea ice. In 1958 Caughley noted that the nucleus of the colony had moved in stages some 1,500 yards westward from its original site by late November, and a similar succession of sites was apparent in each of my visits in 1960–63. Thus the birds retreat toward the apex of the triangular enclave, possibly on to firmer ice which is less likely to disperse before December or January. Similar movements of a breeding colony have been described by Prévost[14] at Pointe Geologie.

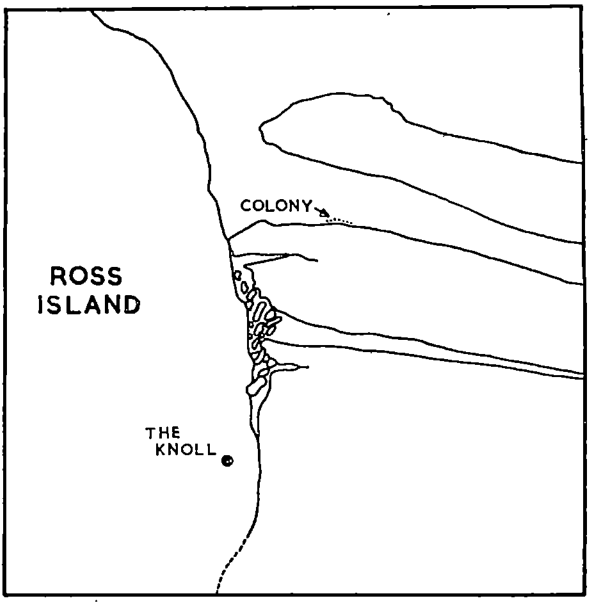

Fig. 2

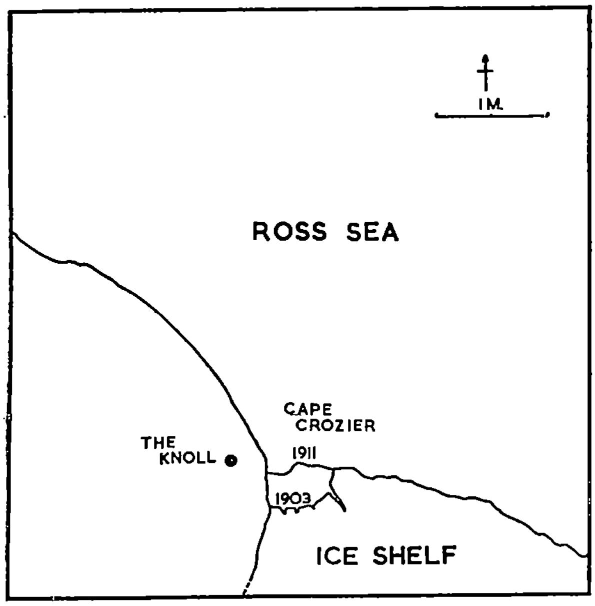

Fig. 1

In comparison with its situation earlier in the century, the colony now enjoys better protection from blizzards and a much longer period of stability late in the breeding season, as the sea ice is unlikely to disperse from the enclaves before mid-December. It is also completely protected from northerly swells early in the breeding season, thus avoiding the possibility of heavy losses through dispersion in June and July. Although sea ice north of the Barrier can probably be dispersed by wind and swell at any time of the year, ice within the enclaves is unlikely to suffer more than slight compression and tension from movement of the shelf blocks on either side. Its surface in early summer is usually buckled, but extremely solid and stable. Snow drifts build up in the lee of the cliffs, but the main spread of sea ice in the enclaves remains remarkably snow-free.

Observations at other colonies have shown that, at least toward the northern edge of their range, chicks are able to complete their moult before the group disperses[5,9], and both Caughley and Budd have questioned Wilson's[2] suggestion that chicks from Cape Crozier complete their moult after the dispersal of the sea ice in summer. However, it is clear that events in the breeding cycle at Cape Crozier occur about a month later than at the more northerly colonies; thus chicks at Pointe Geologie begin their moult early in November, while those at Cape Crozier show the first indications in late November or early December (Caughley in ref. 5 and personal observation). In 1962 at Cape Crozier only about 5–10 per cent of the chicks had lost down from their flipper tips by December 4; more than 50 per cent (including many only half to two-thirds grown) would not have completed their moult before late January or early February. In 1958 open water extended far down the enclave by mid-December, and it seems unlikely that firm ice would normally remain *in situ* after mid-January at the latest. Emperor penguin chicks, like those of king penguins[15], may be able to complete their moult long after their parents have left them, and large, well-fed chicks would not necessarily be at a disadvantage if their colony drifted out to sea in December or January. I see no reason, therefore, for discounting Wilson's suggestion on present evidence.

The census figures for 1961–63 indicate that the Cape Crozier colony is now enjoying a higher breeding success than at any time in its recorded history, and that the

Human Biology

AN INTRODUCTION TO HUMAN EVOLUTION, VARIATION, AND GROWTH

G. A. Harrison, J. S. Weiner, J. M. Tanner, and N. A. Barnicot

With a Foreword by P. B. Medawar

In five sections, this book attempts to synthesize, at an introductory level, present knowledge of the biological organization of past and present human populations. It is intended primarily for university undergraduates reading human biology, anthropology, or medicine, but should also be of value to all who are interested in the general biology of man. *Illustrated 42s net*

Numerical Problems in Advanced Physical Chemistry

J. H. Wolfenden, R. E. Richards and E. E. Richards

This is an attempt to bridge the gap at undergraduate level between the fundamental principles of physical chemistry and some of the actual experiments which are relevant to them. The problems remaining from the first edition have been entirely reworked and in some cases revised, and fifty-one new problems that include many modern topics have been added.
Second edition 30s net

Theories of Nuclear Fission

L. Wilets

The fundamental models of the fission process are presented, analysed and criticized. It is the book's aim to present theories as 'crisply' as feasible. The author not only surveys past contributions to the field, but also includes original material and outlines future avenues of research.

VITAMINE

ihre Chemie und Biochemie

Edited by Dr.-Ing. Ph.M. JIRI FRAGNER, Prague. Translated from the Czech by H. Liebster and E. Hachová of Prague, with a Preface by Prof. Dr. Dr. h.c. K. Täufel, Potsdam-Rehbrücke.

Vol. 1: About 930 pages, 48 illustrations, 117 tables, 16·7 × 24 cm., 1964, cloth-binding. Price about DM 82.

Vol. 2: About 770 pages, 33 illustrations, 83 tables, 39 diagrams, 1 folding dia. on one chart, 16·7 × 24 cm., cloth-binding. Price about DM 66. This volume will probably appear in spring 1965.

The books deal in full detail with all vitamins and factors of vitamin character. The first volume of this standard work includes a general and a special section, while the second volume is devoted exclusively to the treatment of the individual vitamins. The ten chapters of the general section examine numerous problems from the point of view of chemists and biologists, physicians, economists and dieticians, while the special section contains a full treatise of the vitamins in alphabetical sequence, based on the modern international nomenclature recommended by I.U.P.A.C. The book is distinguished for concise and clear presentation of all the subject-matter treated.

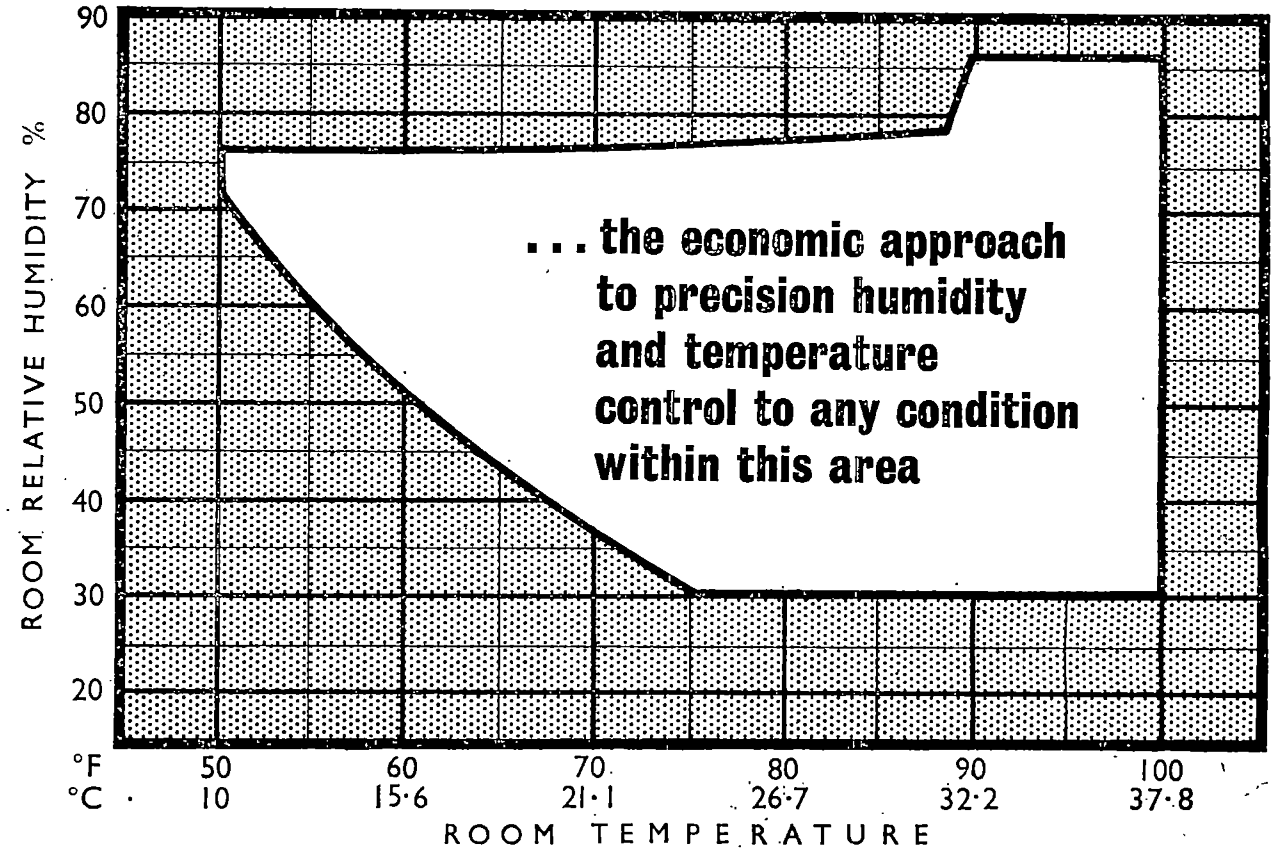
Thermocontrol air-conditioning cabinets



With Air Conditioning Cabinets of the type illustrated, rooms up to 3,000 cubic feet capacity can be conditioned and with agreed installation layouts can be maintained to within ±0.5° F. and ±0.75% R.H. settings overall. The unit is provided with an air outlet raised above bench level and a range of larger units is also available to special design for unusual applications.

The specification of the standard unit includes a replaceable glass-woven filter for air entering the cabinet; centrifugal fan with belt-driven fan motor and starter; cooling coil of up to 55,000 B.T.U.'s extraction per hour for reduction of either temperature or humidity; air heater with built-in high limit thermostat; room thermostat with relays to operate electric heater when the temperature is low, or cooling coil when the temperature is high; humidistat to control relative humidity through evaporative humidifier.

Our specialist Engineers will be pleased to examine and recommend condition equipment for your schemes to ensure maintaining stringent conditions at economic cost.

Water can be a problem

Where cooling water is not readily available and its installation would be difficult or costly – or, as in radioactive areas, expensive to dispose of – an air-cooled oil diffusion pump has outstanding advantages. Plug into the electrical supply and the pump is fully operational.

The AO33C is an air-cooled version of the tried and tested Metrovac water-cooled pump and is completely interchangeable with it as far as vacuum connections, overall length, and heater power are concerned.

Technical Data: Pumping speed for air (unbaffled) 130 1/sec (with Metrovac HB3 baffle valve) 80 1/sec.
Ultimate pressure at 20°-C ambient. Less than 5×10^{-6} torr.
Critical backing pressure 0.4 torr (400 millitorr).

Enquiries are invited for the A033C, or any type of vacuum equipment or component. Technical advice is freely available.

breeding stock has also increased considerably in the past few years. At least 1,450–1,500 pairs bred on the colony in 1961 and 1962, and a similar number may have laid in 1963, suffering higher mortality of eggs or chicks. The colony is visited frequently by members of New Zealand and United States expeditions in McMurdo Sound. While there is no evidence to suggest that normal helicopter movements within the area affect the colony adversely, low-flying aircraft early in the season could inflict serious losses by raising panic in incubating or brooding birds; recommendations are therefore being made against casual visits before the end of October, and flying regulations to cover the remainder of the season are being drafted for submission to New Zealand and American authorities. Plans for future investigations include a programme of chick banding, and reconnaisance flights late in the year to investigate the dispersal and breeding success of the colony.

I thank Prof. G. A. Knox (Department of Zoology, University of Canterbury) for his advice, T. Jacobs, O. Sutherland and I. Spellerberg, who helped with observations, and the Research Committee of the New Zealand University Grants Committee for financial support. Field help was most generously given by *VX* 6 Squadron, U.S. Navy, and the good offices of the Antarctic Division, Department of Scientific and Industrial Research (Mr. G. W. Markham), and the Ross Dependency Research Committee are gratefully acknowledged.
